Graph-Time Convolutional Autoencoders

Anonymous Author(s) Anonymous Affiliation Anonymous Email

Abstract

We introduce graph-time convolutional autoencoder (GTConvAE), a novel spa-2 tiotemporal architecture tailored to unsupervised learning for multivariate time 3 series on networks. The GTConvAE leverages product graphs to represent the 4 time series and a principled joint spatiotemporal convolution over this product 5 graph. Instead of fixing the product graph at the outset, we make it parametric 6 to attend to the spatiotemporal coupling for the task at hand. On top of this, we 7 propose temporal downsampling for the encoder to improve the receptive field 8 in a spatiotemporal manner without affecting the network structure; respectively. 9 In the decoder, we consider the opposite upsampling operator. We prove that the 10 GTConvAEs with graph integral Lipschitz filters are stable to relative network per-11 turbations, ultimately showing the role of the different components in the encoder 12 and decoder. Numerical experiments for denoising and anomaly detection in solar 13 and water networks corroborate our findings and showcase the effectiveness of the 14 GTConvAE compared with state-of-the-art alternatives. 15

16 **1** Introduction

17 Learning unsupervised representations from spatiotemporal network data is commonly encountered 18 in applications concerning multivariate data denoising [1], anomaly detection [2], missing data 19 imputation [3], and forecasting [4], to name just a few. The challenge is to develop models that 20 *jointly* capture the spatiotemporal dependencies in a computation- and data-efficient manner yet being 21 tractable so that to understand the role played by the network structure and the dynamics over it. The 22 autoencoder family of functions is of interest in this setting, but vanilla spatiotemporal forms [5–7] 23 that ignore the network structure suffer the well-known curse of dimensionality and lack inductive 24 learning capabilities [8].

Upon leveraging the network as an inductive bias [9], graph-time autoencoders have been recently 25 developed. These approaches are typically composed of two interleaving modules: one capturing 26 the spatial dependencies via graph neural networks (GNNs) [10] and one capturing the temporal 27 dependencies via temporal CNN or LTSM networks. For example, the work in [1] uses an edge-28 varying GNN [11] followed by a temporal convolution for motion denoising. The work in [12] 29 considers LSTMs and graph convolutions for variational spatiotemporal autoencoders, which have 30 been further investigated in [3, 13], respectively, for spatiotemporal data imputation as a graph-31 based matrix completion problem and dynamic topologies. Graph-time autoencoders over dynamic 32 topologies have also been investigated in [14, 15]. Lastly, [4] embeds the temporal information into 33 the edges of a graph and develops an autoencoder over this graph for forecasting purposes. 34

By working disjointly first on the graph and then on the temporal dimension of the graph embeddings, 35 these approaches fail to capture the joint spatiotemporal dependencies present in the raw data. It is 36 also challenging to analyze their theoretical properties and to attribute to what extent the benefit comes from one module over the other. This aspect has been investigated for supervised spatiotemporal 38 learning via GNNs [16–21] but not for autoencoders. The two works elaborating on this are [2] 39 and [22]. The work in [2] replicates the graph over time via the Cartesian product principle [23] 40 and uses an order one graph convolution [24] to learn spatiotemporal embeddings that are fed 41 into an LSTM module to improve the temporal memory, ultimately giving more importance to the 42 temporal dimension of the latent representation. Differently, [25] proposed a variational graph-time 43

autoencoder that its encoder is based on [17] and its decoder is a multi-layer perceptron; hence, being 44

suitable only for topological tasks such as dynamic link prediction but not for tasks concerning time 45

series over networks such as denoising or anomaly detection. 46

In this paper, we propose a GTConvAE that, differently from [2], captures *jointly* the spatiotemporal 47 coupling both in the raw data and the intermediate higher-level representations. The GTConvAE 48 operates over a parametric product graph [26] to attend to the spatiotemporal coupling for the task 49 at hand rather than fixing it at the outset. Differently from [17], the GTConvAE has a symmetric 50 structure with graph-time convolutions in both encoder and decoder, making it suitable for tasks 51 concerning network time series. We also study the capability of the GTConvAE to transfer learning 52 across different networks, which is of importance as practical topologies differ from the models used 53 during training (e.g., because of model uncertainness, perturbations, or dynamics). The latter has 54 been studied for traditional [27–29] and graph-time GNN models [20, 26, 30] but not for graph-time 55 autoencoders. 56

Our contribution in this paper is twofold. First, we propose a symmetric graph-time convolutional 57 autoencoder that jointly captures the spatiotemporal coupling in the data suited for tasks concerning 58 multivariate time series over networks. The GTConvAE represents the time series as a graph signal 59 over product graphs and uses the latter as an inductive bias to learn unsupervised representations. 60 The product graph is parametric to attend to the coupling for the specific task, and it generalizes 61 the popular choices of product graphs [31]. We also propose a temporal downsampling/upsampling 62 in the encoder/decoder to increase the spatiotemporal receptive field without affecting the network 63 structure; hence, preserving the inductive bias. Second, we prove GTConvAE is stable to relative 64 perturbations on the spatial graph; highlighting the role played by the encoder, decoder, parametric 65 product graph, convolutional filters, and downsampling/upsampling rate. Numerical experiments 66 about denoising and anomaly detection over solar and water networks corroborate our findings and 67 show a competitive performance compared with the more involved state-of-the-art alternatives. 68

The rest of this paper is organized as follows. Section 2 formulates the GTConvAE model and 69 Section 3 analyzes its theoretical properties. Numerical experiments are presented in Section 4 and 70 conclusions in Section 5. The proofs are collected in the appendix. 71

Graph-Time Convolutional Autoencoders 2 72

GTconvAE learns representations from N-dimensional multivariate time series $\mathbf{x}_t \in \mathbb{R}^N, t = 1, \dots, T$, collected in matrix $\mathbf{X} \in \mathbb{R}^{N \times T}$. These time series have a spatial network structure 73 74 represented by a graph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ composed of N nodes $\mathcal{V} = \{v_1, \dots, v_N\}$ and M edges. The *n*-th row of **X** contains the time series $\mathbf{x}^n = [x_1(n), \dots, x_T(n)]^\top$ on node v_n and the *t*-th column a 75 76 graph signal $\mathbf{x}_t = [x_t(1), \dots, x_t(N)]^{\top}$ at timestamp t [32, 33]. For example, the time series could 77 78 be nodal pressures measured over junction nodes in a water distribution network, while the pipe connections rule the spatial structure. The representations learned from the tuple $\{\mathcal{G}, \mathbf{X}\}$ can then be 79 used, among others, for anomaly detection [5], denoising dynamic data over graphs [1], and missing 80 data completion [3]. 81

The GTconvAE follows the standard encoder-decoder structure [34], but in each module, it *jointly* 82 83

captures the spatiotemporal structure in the data. We denote the GTconvAE as

$$\hat{\mathbf{X}} = \text{GTConvAE}(\mathbf{X}, \mathcal{G}; \mathcal{H}) := \text{DEC}(\text{ENC}(\mathbf{X}, \mathcal{G}; \mathcal{H}_e), \mathcal{G}; \mathcal{H}_d)$$

where the encoder $\text{ENC}(\cdot, \cdot; \mathcal{H}_e)$ and decoder $\text{DEC}(\cdot, \cdot; \mathcal{H}_d)$ are non-linear parametric functions and 84 where set $\mathcal{H} = \mathcal{H}_e \cup \mathcal{H}_d$ collects all parameters. The encoder takes as input the graph \mathcal{G} and the time 85 series X and produces higher-level representations $\mathbf{Z} \in \mathbb{R}^{N \times T_e}$. These representations are built in 86 a layered manner where each layer comprises: i) a joint graph-time convolutional filter to capture 87 the spatiotemporal dependencies in a principled manner; ii) a temporal downsampling module to 88 increase the receptive field without affecting the network structure; and iii) a pointwise nonlinearity 89 to have more complex representations. The decoder has a mirrored structure w.r.t. the encoder by 90 taking as input \mathbf{Z} and outputting an estimate of the input \mathbf{X} . The model parameters are estimated 91 end-to-end by minimizing a spatiotemporal regularized reconstruction loss $\mathcal{L}(\mathbf{X}, \hat{\mathbf{X}}, \mathcal{G}, \mathcal{H})$. 92

93 2.1 Product Graph Representation of Network Time Series

GTConvAE uses product graphs to represent the spatiotemporal dependencies in X [23]. Product 94 graphs have been proven successful for processing multivariate time series, such as imputing missing 95 values [35, 36], denoising [37], providing a spatiotemporal Fourier analysis [33], as well as building 96 vector autoregressive models [38], spatiotemporal scattering transforms [39], and graph-time neural 97 networks [26]. Specifically, denote by $\mathbf{S} \in \mathbb{R}^{N \times N}$ the graph shift operator (GSO) of the spatial graph 98 \mathcal{G} , e.g., adjacency, Laplacian. Consider also a temporal graph $\mathcal{G}_T = (\mathcal{V}_T, \mathcal{E}_T, \mathbf{S}_T)$, where the node 99 set $\mathcal{V}_T = \{1, \dots, T\}$ comprises the discrete-time instants, the edge set $\mathcal{E}_T \subseteq \mathcal{V}_T \times \mathcal{V}_T$ captures the temporal dependencies; e.g., a directed line or a cyclic graph, and $\mathbf{S}_T \in \mathbb{R}^{N \times N}$ is the respective 100 101 GSO [40, 41]. The time series \mathbf{x}^n now can be defined as a graph signal over temporal graph \mathbf{S}_T 102 where $x_t(n)$ is a scalar value assigned to the t-th node of \mathcal{G}_T . 103

The product graph representing the spatiotemporal patterns in **X** is denoted by $\mathcal{G}_{\diamond} = \mathcal{G}_T \diamond \mathcal{G} = (\mathcal{V}_{\diamond}, \mathcal{E}_{\diamond}, \mathbf{S}_{\diamond})$. The node set \mathcal{V}_{\diamond} is the Cartesian product between \mathcal{V}_T and \mathcal{V} which leads to NT distinct spatiotemporal nodes $i_{\diamond} = (n, t)$. The edge set \mathcal{E}_{\diamond} connects these nodes and the GSO $\mathbf{S}_{\diamond} \in \mathbb{R}^{NT \times NT}$ is dictated by the product graph. Fixing the product graph implies fixing the spatiotemporal dependencies in the data, which may lead to wrong inductive biases. To avoid this and improve flexibility, we consider a parametric product graph whose GSO is of the form

$$\mathbf{S}_{\diamond} = \sum_{i=0}^{1} \sum_{j=0}^{1} s_{ij} (\mathbf{S}_{T}^{i} \otimes \mathbf{S}^{j}) = \underbrace{s_{00} \mathbf{I}_{T} \otimes \mathbf{I}_{N}}_{\text{self-loops}} + \underbrace{s_{01} \mathbf{I}_{T} \otimes \mathbf{S} + s_{10} \mathbf{S}_{T} \otimes \mathbf{I}_{N}}_{\text{Cartesian}} + \underbrace{s_{11} \mathbf{S}_{T} \otimes \mathbf{S}}_{\text{Kronecker}}, \quad (1)$$

where the scalar parameters $\{s_{ij}\}$ attend the spatiotemporal connections and encompass the typical product graph choices such as the Kronecker, the Cartesian, and the strong product. By columnvectorizing **X** into $\mathbf{x}_{\diamond} = \text{vec}(\mathbf{X}) \in \mathbb{R}^{NT}$, we obtain a product graph signal assigning a real value to each spacetime node i_{\diamond} . I.e., the dynamic data \mathbf{x}_t over \mathcal{G} is now a static signal \mathbf{x}_{\diamond} over the product graph \mathcal{G}_{\diamond} .

115 2.2 Encoder

- The encoder is an L_e -layered architecture in which each layer comprises a bank of product graph convolutional filters, temporal downsampling, and pointwise nonlinearities.
- **GTConv filter** captures the spatiotemporal patterns in the data matrix **X**. Given the parametric product graph representation $\mathcal{G}_{\diamond} = (\mathcal{V}_{\diamond}, \mathcal{E}_{\diamond}, \mathbf{S}_{\diamond})$ [cf. (1)] and the product graph signal $\mathbf{x}_{\diamond} = \text{vec}(\mathbf{X})$ as input, the output of a graph-time convolutional filter of order K is

$$\mathbf{y}_{\diamond} = \mathbf{H}(\mathbf{S}_{\diamond})\mathbf{x}_{\diamond} = \sum_{k=0}^{K} h_k \mathbf{S}_{\diamond}^k \mathbf{x}_{\diamond}$$
(2)

where $\mathbf{h} = [h_0, \dots, h_K]^{\top}$ are the filter parameters and $\mathbf{H}(\mathbf{S}_{\diamond}) := \sum_{k=0}^{K} h_k \mathbf{S}_{\diamond}^k$ the filtering matrix. The filter in (2) is called convolutional as the output \mathbf{y}_{\diamond} is a weighted linear combination of shifted graph signals over the product graph up to K times [42]. Hence, the filter is spatiotemporally local in a neighborhood of radius K. The filter locality does not only depend on the order K but also on the type of product graph. For example, for a fixed K, the Cartesian product is more localized than the strong product, which can be considered to have a longer spatiotemporal memory [26]. Consequently, learning parameters $\{s_{ij}\}$ in (1) implies learning the multi-hop resolution radius.

In the ℓ -th layer, the encoder has $F_{\ell-1}$ product graph signal features $\mathbf{x}_{\diamond,\ell-1}^1, \ldots, \mathbf{x}_{\diamond,\ell-1}^g, \ldots, \mathbf{x}_{\diamond,\ell-1}^{F_{\ell-1}}$, processes these with a bank of $F_{\ell}F_{\ell-1}$ filters and outputs F_{ℓ} product graph signal features as

$$\mathbf{y}_{\diamond,\ell}^{f} = \sum_{g=1}^{F_{\ell-1}} \mathbf{H}^{fg}(\mathbf{S}_{\diamond}) \mathbf{x}_{\diamond,\ell-1}^{g}, \quad f = 1, \dots F_{\ell},$$
(3)

130 which are the higher-level linear representation of the layer.

Temporal downsampling reduces the temporal dimension in each output $\{\mathbf{y}_{\diamond,\ell}^{t}\}_{f}$ in (3) by downsampling the latter along the temporal dimension with a rate r. More specifically, we first transform the *f*-th output $\mathbf{y}_{\diamond,\ell}^f \in \mathbb{R}^{NT_{\ell-1}^e}$ into a matrix $\mathbf{Y}_1^f = \operatorname{vec}^{-1}(\mathbf{y}_{\diamond,1}^f) \in \mathbb{R}^{N \times T_{\ell-1}^e}$ and then summarize every *r* consecutive columns without overlap to obtain the downsampled matrix $\mathbf{X}_{d,\ell}^f \in \mathbb{R}^{NT_{\ell}^e}$ with

135 $T_{\ell}^e < T_{\ell-1}^e$. The (n,t)-th entry of $\mathbf{X}_{d,\ell}^f$ is computed as

$$\mathbf{X}_{d,\ell}^{f}(n,t) = \text{SUM}\big(\mathbf{Y}_{\ell}^{f}(n,r(t-1)+1:rt)\big), \quad f = 1,\dots F_{\ell},\tag{4}$$

where SUM(·) is a summary function over the temporal indices r(t-1) + 1 to rt. This summary

function could be a simple downsampling (i.e., output the first column in the block $\mathbf{Y}_{\ell}^{f}(n, r(t-1)+1: t_{\ell})$) or an aggregation function (i.e., mean/max/min per spatial node).

This temporal downsampling increases the encoder spatiotemporal memory without affecting the 139 spatial structure. I.e., nodes with the temporal indices $t, rt, (r+1)t, \ldots$ become neighbors, which 140 brings in a longer memory in the next layer and increases the encoder receptive field. While also 141 spatial graph pooling can be added [43], we do not advocate it for two reasons. First, the spatial 142 graph acts as an inductive bias for the GTConvAE [9]; hence, changing the graph in the layers via 143 graph reduction, coarsening, or alternatives will affect the spatial structure, ultimately changing the 144 inductive bias. Second, the spatial graph often represents the communication channels for distributed 145 implementation of GTConv [20, 42, 44], and changing it may be physically impossible as sensor 146 nodes have a limited transmission radius. An option in the latter setting may be a zero-pad spatial 147 pooling [45, 46] but it requires memorizing the indices where the zero-padding is applied, which may 148 be challenging for large graphs. 149

Activation functions nonlinearize the downsampled features to increase the representational capacity.

We consider an entry-wise nonlinear function $\sigma(\cdot)$ such as ReLU and produce layer ℓ -th output as

$$\mathbf{X}_{\ell+1}^f = \sigma(\mathbf{X}_{d,\ell}^f), \quad f = 1, \dots F_\ell.$$
(5)

The encoder performs operations (3)-(4)-(5) for all the L_e layers to yield the encoded output

$$\mathbf{Z}_{\diamond} := \mathbf{X}_{\diamond,L} = \text{ENC}(\mathbf{x}_{\diamond,0}, \mathbf{S}, \mathbf{S}_T; \mathcal{H}_e, \mathbf{s}), \tag{6}$$

where $\mathbf{x}_{\diamond,0} := \mathbf{x}_{\diamond} \in \mathbb{R}^{NT}$, $\mathbf{Z}_{\diamond} = [\mathbf{z}_{\diamond}^{1}, \dots, \mathbf{z}_{\diamond}^{F_{L}}] \in \mathbb{R}^{NT_{L_{e}} \times F_{L}}$, and we made explicit the dependence from the product graph parameters $\mathbf{s} = [s_{00}, s_{01}, s_{10}, s_{11}]^{\top}$ [cf. (1)].

155 **2.3 Decoder**

¹⁵⁶ Mirroring the encoder, the decoder reconstructs the input from the latent representations in (6). At the ¹⁵⁷ generic layer ℓ , graph-time convolutional filtering is performed, subsequently a temporal upsampling, ¹⁵⁸ and a pointwise nonlinearity.

GTConv filtering decodes the spatiotemporal latent representations from the encoder. Considering again $F_{\ell-1}$ input features $\mathbf{z}_{\diamond,\ell-1}^1, \ldots, \mathbf{z}_{\diamond,\ell-1}^{g}$ and a filter bank of $F_{\ell}F_{\ell-1}$ GTConv filters as per (2), the outputs are

$$\mathbf{y}_{\diamond,\ell}^{f} = \sum_{g=1}^{F_{\ell-1}} \mathbf{H}^{fg}(\mathbf{S}_{\diamond}) \mathbf{z}_{\diamond,\ell-1}^{g}, \quad f = 1, \dots F_{\ell}.$$
 (7)

¹⁶² Upsampling zero-pads the removed temporal values during downsampling [cf. (4)] so that the final

GTConvAE output matches the dimension of **X**. Specifically, given the f-th feature $\mathbf{y}_{\diamond,\ell}^f \in \mathbb{R}^{NT_{\ell-1}^d}$ from (7), we again transform it into a matrix $\mathbf{Y}_1^f = \text{vec}^{-1}(\mathbf{y}_{\diamond,1}^f) \in \mathbb{R}^{N \times T_{\ell-1}^d}$ and obtain the upsampled matrix $\mathbf{Z}_{u,\ell}^f \in \mathbb{R}^{N \times T_{\ell}^d}$ whose (n, t)-th entry is computed as

$$\mathbf{Z}_{u,\ell}^{f}(n,t) = \begin{cases} \mathbf{Y}_{\ell}^{f}(n, \lceil t/r \rceil); & \text{if } \exists k \in \mathbb{Z} : t = kr \\ 0; & \text{o/w} \end{cases}$$
(8)

where $\lceil \cdot \rceil$ is the ceiling function.¹ The GTConv filter bank in the next layer interpolates these zero-padded values from the downsampled ones. This implies that the downsampling rate in the

¹We considered the same down/up-sampling rate in each layer of the decoder and encoder; hence, because of the mirrored structure T_{ℓ}^{e} in (5) equals $T_{\ell-1}^{d}$ in (8).

- encoder cannot be too harsh to lose information, and also, the filter orders in the decoder cannot be
- too small to have a high interpolatory capacity.
- 170 Activation functions again nonlinzearize the upsampled features in (8) and yield

$$\mathbf{Z}_{\ell}^{f} = \sigma(\mathbf{Z}_{u,\ell}^{f}), \quad f = 1, \dots F_{\ell}.$$
(9)

The decoder performs operations (7)-(8)-(9) for all L_d layers to yield the decoded output $\hat{\mathbf{x}}_{\diamond} = \mathbf{z}_{\diamond,L_d} \in \mathbb{R}^{NT}$, which also corresponds to the GTConvAE output

$$\hat{\mathbf{x}}_{\diamond} = \mathbf{z}_{\diamond, L_d} = \text{DEC}(\mathbf{Z}_{\diamond}, \mathbf{S}, \mathbf{S}_T; \mathcal{H}_d, \mathbf{s}), \tag{10}$$

where we match the dimensions by setting $F_{L_d} = 1$.

174 2.4 Loss Function

Given (6) and (10), the GTConvAE in (1) can be detailed as 175

$$\hat{\mathbf{x}}_{\diamond} = \text{GTConvAE}(\mathbf{x}_{\diamond}, \mathbf{S}, \mathbf{S}_T; \mathcal{H}, \mathbf{s}) = \text{DEC}(\text{ENC}(\mathbf{x}_{\diamond}, \mathbf{S}, \mathbf{S}_T; \mathcal{H}_e, \mathbf{s}), \mathbf{S}, \mathbf{S}_T; \mathcal{H}_d, \mathbf{s}).$$
(11)

The GTConv filter parameters in \mathcal{H} and the product graph parameters in s are estimated by minimizing the loss function

$$\mathcal{L}(\mathbf{X}, \mathbf{X}, \mathcal{G}, \mathcal{H}) = \mathbb{E}_{\mathcal{D}}\left[\|\mathbf{x}_{\diamond} - \hat{\mathbf{x}}_{\diamond}\|_{2} \right] + \rho \|\mathbf{s}\|_{1}.$$
(12)

where the first term measures the reconstruction error over the probabilistic distribution \mathcal{D} of the

training set, whereas the second term imposes sparsity in the spatiotemporal dependencies of the

product graph. Scalar $\rho > 0$ controls the trade-off between fitting and regularization, and a higher value implies a stronger spatiotemporal sparsity (from the norm one $\|\cdot\|_1$); i.e., sparser spatiotemporal

182 attention.

Complexity analysis: Denoting the maximum number of features in all layers by $F_{max} = \max\{F_\ell\}$ 183 the GTConvAE has $|\mathcal{H}| = (L_e + L_d)(K+1)F_{max}^2$ parameters. This is because each GTConv filter 184 (2) has K + 1 parameters and in each layer a filter bank of at most F_{max}^2 filters is used. Despite the 185 product graphs are of large dimensions, the latter is highly sparse and the computation complexity of 186 the GTConvAE is of order $\mathcal{O}(M_{\diamond}|\mathcal{H}|)$, where $M_{\diamond} = NT + NM_T + MT + 2MM_T$ is the number 187 of edges of the product graph (M edges in the spatial graph and M_T edges in the temporal graph). 188 This is because each graph-time filter has a computational complexity of order $\mathcal{O}((K+1)M_{\diamond})$ [26] 189 and the GTConvAE consists of $(L_e + L_d)F_{max}^2$ graph-time filters. Note that we consider r = 1190 sampling rate to provide the worst case analysis, but the computational complexity can be further 191 reduced for r > 1. 192

3 Stability Analysis

In this section, we conduct a stability analysis of the GTConvAE w.r.t. relative perturbations in the spatial graph. This stability analysis is motivated by the fact that we do not always have access to the ground truth spatial graph due to modeling issues or when the physical network undergoes slight changes over time. Hence, the spatial graph used for training differs from that used for testing; thus, having a stable GTConvAE is desirable to perform the tasks reliably.

We consider the *relative perturbation* model proposed in [27]

$$\hat{\mathbf{S}} = \mathbf{S} + (\mathbf{S}\mathbf{E} + \mathbf{E}\mathbf{S}) \tag{13}$$

where $\hat{\mathbf{S}}$ is the perturbed GSO and \mathbf{E} is the perturbation matrix with bounded *operator norm* $\|\mathbf{E}\| \le \epsilon$. This model accounts for graph perturbation depending on its structure, i.e., a higher degree node (a node with higher-weighted connected edges) is relatively prone to more perturbation.

203 3.1 Spatiotemporal integral Lipschitz filters

To investigate the stability of GTConvAE, we first characterize the graph-time convolutional filters in the spectral domain. Consider the eigendecompositions of the spatial GSO $\mathbf{S} = \mathbf{V} \mathbf{\Lambda} \mathbf{V}^{\mathsf{H}}$ and of the temporal GSO $\mathbf{S}_T = \mathbf{V}_T \mathbf{\Lambda}_T \mathbf{V}_T^{\mathsf{H}}$. Matrices $\mathbf{V} = [\mathbf{v}_1, \dots, \mathbf{v}_N]^{\mathsf{T}}$ and $\mathbf{V} = [\mathbf{v}_{T,1}, \dots, \mathbf{v}_{T,T}]^{\mathsf{T}}$ collect the spatial and the temporal eigenvectors, respectively, and $\mathbf{\Lambda} = \text{diag}(\lambda_1, \dots, \lambda_N)$ and

 $\Lambda_T = \text{diag}(\lambda_{T,1}, \dots, \lambda_{T,T})$ the corresponding eigenvalues. From (1), the eigendecomposition of 208 the product graph GSO is $\mathbf{S}_{\diamond} = \mathbf{V}_{\diamond} \mathbf{\Lambda}_{\diamond} \mathbf{V}_{\diamond}^{\mathsf{H}}$ with eigenvectors $\mathbf{V}_{\diamond} = \mathbf{V}_T \otimes \mathbf{V}$ being the Kronecker 209 product \otimes of the respective GSOs and the eigenvalues $\Lambda_{\diamond} = \Lambda_T \diamond \Lambda$ are defined by the product graph 210 rule. As in graph signal processing [32], it is possible to characterize the joint graph-time Fourier 211 transform of product graph signals. Specifically, the graph-time Fourier of signal \mathbf{x}_{\diamond} is defined as 212 $\tilde{\mathbf{x}} = (\mathbf{V}_T \otimes \mathbf{V})^{\mathsf{H}} \mathbf{x}_{\diamond}$ and the eigenvalues in $\mathbf{\Lambda}_{\diamond}$ now collect the graph-time frequencies of the product 213 graph [33]. Applying this Fourier transform on the input and output of the GTConv filter in (2), we 214 can write the filter input-output as $\tilde{\mathbf{y}}_{\diamond} = \mathbf{H}(\mathbf{\Lambda}_{\diamond})\tilde{\mathbf{y}}$, where $\tilde{\mathbf{y}}_{\diamond}$ is the Fourier transform of the output 215 and $\mathbf{H}(\mathbf{\Lambda}_{\diamond})$ is an $NT \times NT$ diagonal matrix containing the filter *frequency response* on the main 216 217 diagonal. This frequency response is of the form

$$h(\lambda_{\diamond,(n,t)}) = \sum_{k=0}^{K} h_k \lambda_{\diamond,(n,t)}^k$$
(14)

where $\lambda_{\diamond,(n,t)} = \lambda_{T,t} \diamond \lambda_n$ indicates the eigenvalue of \mathbf{S}_{\diamond} corresponding to the spatial index $n \in [N]$ and temporal index $t \in [T]$ of the product graph.

The eigenvalues $\lambda_{\diamond,(n,t)}$ can be considered as the frequencies of the product graph and can be ordered in ascending order of magnitude. We can then characterize the variation of the filter frequency response for two different spatial eigenvalues.

Definition 1. A GTConv filter with a frequency response $h(\lambda_{\diamond,(n,t)})$ is graph integral Lipschitz if there exists constant C > 0 such that for all frequencies $\lambda_{\diamond,(n,t)}, \lambda_{\diamond,(n',t')} \in \mathbf{A}_{\diamond}$, it holds that

$$|h(\lambda_{\diamond,(n,t)}) - h(\lambda_{\diamond,(n',t')})| \le C \frac{|\lambda_n - \lambda_{n'}|}{|\lambda_n + \lambda_{n'}|/2} \quad \text{for all} \quad \{\lambda_n, \lambda_{n'}\} \in \mathbf{\Lambda}.$$
 (15)

225

Expression (15) states that the frequency response of graph-time convolutional filter should vary sub-linearly while the coefficient depends on the gap $|\lambda_{\diamond,(n,t)} + \lambda_{\diamond,(n',t')}|/2$. This implies

$$\left|\lambda_n \frac{\partial h(\lambda_{\diamond,(n,t)})}{\partial \lambda_n}\right| \le C \quad \text{for all} \quad \lambda_n \in \mathbf{\Lambda} \quad and \quad \lambda_{\diamond,(n,t)} \in \mathbf{\Lambda}_\diamond \tag{16}$$

which means the integral Lipschitz filter cannot vary drastically in high frequencies. Hence, such a filter can discriminate low frequency content but not high frequency ones.

Definition 2. A graph-time convolutional filter has normalized frequency response if $|h(\lambda_{\diamond,(n,t)})| \le 1$ for all $\lambda_{\diamond,(n,t)} \in \mathbf{A}_{\diamond}$.

This definition is a direct consequence of normalizing the filters' frequency response by their maximum value. We shall show next that GTConvAE with filters satisfying Def. 1 and 2 are stable to perturbations in the form (13).

235 3.2 Stability result

²³⁶ The following theorem with proof in Appendix A provides the main result.

Theorem 1. Consider a GTConvAE with an L_e -layer encoder and an L_d -layer decoder having $F_{\ell} \leq F_{max}$ and $F_{d,\ell} \leq F_{max}$ features per layer in encoder and decoder, respectively, and a summary function $SUM(\cdot)$ performing pure downsampling with rate r. Consider also the filters are integral Lipschitz [cf. Def. 1] with a normalized frequency response [cf. Def. 2] and that the nonlinearities are 1-Lipschitz (e.g., ReLU, absolute value). Let this GTConvAE be trained over the product graph (1) and deployed over its perturbed version whose spatial GSO is given in (13) with a perturbation of at most $\|\mathbf{E}\| \leq \epsilon$. The distance between the two models is upper bounded by

$$\|\operatorname{GTConvAE}(\mathbf{x}_{\diamond}, \mathbf{S}, \mathbf{S}_{T}) - \operatorname{GTConvAE}(\mathbf{x}_{\diamond}, \hat{\mathbf{S}}, \mathbf{S}_{T})\|_{2} \le (L_{d} + L_{e})r^{-L_{e}/2}\epsilon\Delta F_{max}^{L_{e}+L_{d}-1}\|\mathbf{x}_{\diamond}\|_{2}.$$
(17)

where $\Delta = 2C(s_{01} + s_{11}\lambda_{T,max})(1 + \delta\sqrt{NT})$, and $\delta = (\|\mathbf{U} - \mathbf{V}\|^2 + 1)^2 - 1$ with eigenvectors U from $\mathbf{E} = \mathbf{U}\mathbf{M}\mathbf{U}^{\mathsf{H}}$ and \mathbf{V} from $\mathbf{S} = \mathbf{V}\mathbf{\Lambda}\mathbf{V}^{\mathsf{H}}$.

The result (17) states that GTConvAE is stable against relative perturbations. It also suggests that GTConvAE is less stable for larger product graphs (\sqrt{NT}) since more nodes pass information over the perturbed edges. Moreover, making the model more complex by increasing the number of features or layers compromises stability as more graph-time convolutional filters work on a perturbed graph $(F_{max}^{L_e+L_d-1})$. We also see the stability improves with the sampling rate r > 1 because fewer nodes operate over the perturbed graph after downsampling. Furthermore, for a deeper encoder we have more downsampling hence the stability improves; yet there is a tradeoff between improving the bound imposed by the terms $r^{-L_e/2}$, $F_{max}^{L_e+L_d-1}$, and $L_e + L_d$. Finally, parameters s_{01} and s_{11} appear in the stability bound because they are the only ones composing the spatial edges; thus, minimizing $\|\mathbf{s}\|_1$ in (12) leads to improved stability.

256 4 Numerical Results

This section compares the GTConvAE with baseline solutions and competitive alternatives for time series denoising as well as anomaly detection with real data from solar irradiance and water networks. In all experiments, the ADAM optimizer with the standard hyperparameters is used and an unweighted directed line graph is considered for the temporal graph in (1).

4.1 Denoising of solar irradiance time series

We consider the task of denoising solar irradi-262 ance time series over N = 75 solar cities around 263 the northern region of the U.S. measured in GHI 264 (W/m^2) [4]. Each solar city is a vertex and an 265 undirected edge is set using the physical distances between the cities via Gaussian threshold 267 kernel with $\sigma = 0.25$ and th = 0.1 after nor-268 malizing maximum weight to 1 [32]. The noise 269 is generated via a zero-mean Gaussian distri-270 bution with a covariance matrix corresponding 271 to the pseudo-inverse of the normalized graph Laplacian. 273

Experimental setup. We considered the first
2000 samples for training and validation (20002014) and the subsequent 200 (2014-2016) for

Figure 1: Denoising performance of the proposed GTConvAE and alternatives. The standard deviation for all the models is of order 10^{-2} .

testing. The input data is a single feature corresponding to the GHI measurement and the product graph has N = 75 spatial nodes and T = 8 temporal nodes. The GTConvAE has three layers with $\{8, 4, 2\}$ features in the encoder and reversely in the decoder; all filters are 4th-order and normalized Laplacian is used as GSO; a downsampling rate of r = 2; a max function in (4); and ReLU activation functions. The regularizer weight in (12) is $\rho = 0.2$ and the learning rate is 25×10^{-4} . We compared the GTConvAE with the following alternatives:

- *C3D* [5]: non-graph spatiotemporal autoencoder using three-dimensional CNNs.
- *ConvLSTMAE* [7]: A non-graph spatiotemporal autoencoder using two-dimensional CNNs followed by LSTMs.
- *STGAE* [1]: A modular spatiotemporal graph autoencoder that uses an edge varying filter for the graph dimension followed by temporal convolution.
- Baseline GCNN [42]: An autoencoder built with a conventional graph convolutional neural network using the time series as features over the nodes. The shift operator is the normalized Laplacian matrix.

The first two methods are considered to show the role of using a distance graph as an inductive bias. The third method is considered to compare the joint GTConvAE over disjoint alternatives, whereas the last model is considered to show the role of the sparse product graphs rather than treating time series as node features. The parameters for all models are chosen via grid search from the ranges reported in Appendix B.

Results. Fig. 1 shows the reconstruction normalized mean squared error (NMSE) for different signal-to-noise ratios (SNRs). The proposed GTConvAE compares well with STGAE for low SNRs but better for high SNRs. We attribute this improvement to the ability of the GTConvAE to capture

Model	N_A	S	$\mathcal{S}_{ ext{TTD}}$	$\mathcal{S}_{\mathrm{CM}}$	TPR	TNR
STGCAE-LSTM [2]	7	0.924	0.920	0.928	0.892	0.964
TGCN [47]	7	0.931	0.934	0.928	0.885	0.971
GTConvAE (ours)	7	0.940	0.928	0.952	0.922	0.981

Table 1: Comparison of different models in the BATADAL dataset. All metrics are the higher the better.

jointly the spatiotemporal patterns in the data while STGAE operates disjointly. We also see that in comparison with the baseline GCNN, the GTConvAE performs consistently better, highlighting the importance of the sparser product graphs and temporal downsampling. Finally, we also observe a

³⁰² superior performance compared with the non-graph alternatives C3D and ConvLSTMAE.

4.2 Anomaly detection in water networks

We now consider the task of detecting cyber-physical attacks on a water network. We considered the C-town network from the Battle of ATtack Detection ALgorithms (BATADAL) dataset comprising N = 388 nodes (demand junctions, storage tanks, and reservoirs) and 8762 hourly measurements of 43 different node feature signals for a period of 12 months. We used the same setup as in [47] and considered a correlation graph from the data. The dataset provides a normal operating condition comprising recordings for the first 12 months and an anomalous event operating condition comprising 7 attacks over the successive 3 months. Refer to [48, 49] for more detail about the BATADAL dataset.

311 **Experimental setup.** The normal operating condition data are used to train the model for one-step forecasting to be used for detecting anomalies. The anomalous event operating condition data is 312 used for testing and an anomaly is flagged if the prediction error exceeds a fixed threshold. We 313 set the threshold intuitively to three times the error variance during training. The inputs are the 43314 time series over the N = 388 nodes and we considered T = 6 for the temporal graph dimension. 315 The GTConvAE has two layers with $\{8,2\}$ features in the encoder and reversely in the decoder; all 316 317 filters are of order K = 4; a downsampling rate r = 2; a max function in (4); and ReLU activation functions. The regularizer weight in (12) is $\rho = 0.14$ and learning rate is 5×10^{-4} . We compared 318 the performance against two graph-based alternatives: 319

- *STGCAE-LSTM* [2]: A related solution to our method that uses a Cartesian spatiotemporal graph with graph convolutions followed by an LSTM in the latent domain.
- *TGCN* [47]: A modular graph-based autoencoder using cascades of temporal convolutions and message passing.

The parameters for all models are obtained via grid search from the ranges reported in Appendix C. We measure the performance via the S-score present in the BATADAL dataset, which contains S_{TTD} for the timing in detecting anomalies and S_{CM} for the classification accuracy. The S-score is defined as

$$\mathcal{S} = 0.5(\mathcal{S}_{\text{TTD}} + \mathcal{S}_{\text{CM}}) = 0.5\left(\left(1 - \frac{1}{N_A}\sum_{i=1}^{N_A}\frac{\text{TTD}_i}{\Delta T_i}\right) + \frac{\text{TPR+TNR}}{2}\right),\tag{18}$$

where N_A is the number of attacks, TTD is the detection time of the attack, ΔT_i is the duration of the *i*-th attack, TPR is the true positive rate, and TNR is the true negative rate.

Results: Table 1 shows that all the models managed to detect all of the attacks, however, the TGCN has a better performance in timing S_{TTD} . This is due to the calibration of the threshold in their work with a validation dataset while we used a fixed intuitive threshold only based on training. In the accuracy of anomaly detection S_{CM} , the GTConvAE outperforms the other two models as the product graphs alongside downsampling enable it to learn spatiotemporal patterns in the data effectively. Overall, the GTConvAE performs better than other models by a small margin.

Figure 2: Stability results for different scenarios of the GTConvAE and fixed product graphs. (a) Different SNRs in the topology. (b) Different graph sizes in 4dB perturbation. (c) Different sampling rates r.

336 4.3 Stability analysis

To investigate the stability of the GTConvAE, we trained the model over a synthesized dataset so we could control all the settings such as the spatial graph size N. The graph is an undirected stochastic block model with 5 communities among $N = \{50, 100, \dots, 500\}$. The edges are drawn independently with probability 0.8 for nodes in the same community and 0.2 otherwise. Each data sample is a diffused signal over the graph $\mathbf{X} = [\mathbf{Sx}, \dots, \mathbf{S}^T\mathbf{x}]$ with T = 6 and \mathbf{x} having a random non-zero entry. The autoencoder is used to reconstruct this data.

Experimental setup The model has two layers of encoder and decoder with sampling rate r = 2. 343 Each layer of the encoder has $\{8, 4\}$ features and reversely in the decoder. All filters are of order 344 345 four and the normalized graph Laplacian is used as GSO. The activation functions are ReLU and 346 pure donwsampling is considered. The regularizer weight is 0.25 and learning rate is 25×10^{-3} . The model is trained over the graph with different sizes and tested with a perturbed graph following 347 the relative perturbation model in (13) for different SNR scenarios in the topology. We compare the 348 stability of the GTConvAE with learned graphs with the same autoencoder having fixed Cartesian 349 and strong product graphs. 350

Results Fig. 2a indicates that the GTConvAE in different noisy scenarios. GTConvAE is the most stable in medium and high SNRs as it leverages sparsity in the spatiotemporal coupling. However, GTConvAE performance drops more rapidly in low SNR scenarios as its parameters are trained for the data and task. Fig. 2b shows the results for reconstruction error over graphs with different sizes. The GTConvAE is more stable than the other models, even in graphs with the larger sizes for the same reason as before. All the models lose performance similarly as the size of the graph grows. This is consistent with the theoretical result in (17).

358 5 Conclusion

We introduced GTConv-AE as an unsupervised model for learning representations from multivariate 359 time series over networks. The GTConv-AE uses parametric product graphs to aggregate information 360 from a spatiotemporal neighborhood while it yet learns spatiotemporal couplings in the product graph. 361 We proposed a spectral analysis for GTConv-AE due to its convolutional nature which led to stability 362 analysis. The stability analysis states that GTConv-AE is stable against relative perturbations in 363 the spatial graph as long as graph-time filters vary smoothly over high spatiotemporal frequencies. 364 Finally, numerical results showed that the GTConv-AE compares well with the state-of-the-art models 365 on benchmark datasets and corroborated the stability results. 366

516 A Stability proof

The proof is structured in three components. First we prove the graph-time convolutional filter is stable to perturbations. Then, we prove stability for the encoder and finally for the decoder. Throughout the proof we will use the following lemmas.

Lemma 1. [27] Let $\mathbf{S} = \mathbf{V} \mathbf{\Lambda} \mathbf{V}^{\mathsf{H}}$ and $\mathbf{E} = \mathbf{U} \mathbf{M} \mathbf{U}^{\mathsf{H}}$ such that $\|\mathbf{E}\| \leq \epsilon$. Assume that $\mathbf{E}_{V} = \mathbf{V} \mathbf{M} \mathbf{V}^{\mathsf{H}}$ is the projection of perturbation \mathbf{E} over graph eigenspace of \mathbf{S} , and $\mathbf{E} = \mathbf{E}_{V} + \mathbf{E}_{U}$. For any eigenvector \mathbf{v}_{n} of \mathbf{S} it holds that

$$\mathbf{E}\mathbf{v}_n = m_n \mathbf{v}_n + \mathbf{E}_U \mathbf{v}_n \tag{19}$$

with $\|\mathbf{E}_U\| \le \epsilon \delta$, where $\delta = (\|\mathbf{U} - \mathbf{V}\|^2 + 1)^2 - 1$ and m_n is the *n*-th eigenvalue of **M**. Recall that $\|\cdot\|$ represents the operator norm of a matrix.

Lemma 2. Given the frequency response of a graph-time convolutional filter as $h(\lambda_{\diamond}) = \sum_{k=1}^{K} h_k \lambda_{\diamond}^k$, the partial derivation w.r.t. graph frequency λ is

$$\frac{\partial h(\lambda_{\diamond})}{\partial \lambda} = (s_{01} + s_{11}\lambda_T) \sum_{k=1}^{K} kh_k \lambda_{\diamond}^{k-1}.$$
(20)

⁵²⁷ *Proof.* Using the product graph definition (1) we have

$$\frac{\partial \lambda_{\diamond}}{\partial \lambda} = \frac{\partial (s_{00} + s_{01}\lambda + s_{10}\lambda_T + s_{11}\lambda_T\lambda)}{\partial \lambda} = s_{01} + s_{11}\lambda_T.$$
(21)

528 Then,

$$\frac{\partial h(\lambda_{\diamond})}{\partial \lambda} = \frac{\partial h(\lambda_{\diamond})}{\partial \lambda_{\diamond}} \times \frac{\partial \lambda_{\diamond}}{\partial \lambda} = \left(\sum_{k=1}^{K} k h_k \lambda_{\diamond}^{k-1}\right) (s_{01} + s_{11} \lambda_T)$$
(22)

529 completes the proof.

⁵³⁰ To ease notation, let us also rearrange the parametric product graph GSO as

$$\mathbf{S}_{\diamond} = (s_{00}\mathbf{I}_T + s_{10}\mathbf{S}_T) \otimes \mathbf{I}_N + (s_{01}\mathbf{I}_T + s_{11}\mathbf{S}_T) \otimes \mathbf{S} = \mathbf{S}_{T0} \otimes \mathbf{I}_N + \mathbf{S}_{T1} \otimes \mathbf{S}$$
(23)

where $\mathbf{S}_{T0} = s_{00}\mathbf{I}_T + s_{10}\mathbf{S}_T$ collects the fully temporal edges and $\mathbf{S}_{T1} = s_{01}\mathbf{I}_T + s_{11}\mathbf{S}_T$ the edges ruled by the spatial graph.

533 GTConv filter stability.

⁵³⁴ The difference of the filter operating on the perturbed and nominal graph is

$$\mathbf{H}(\mathbf{S}_{\diamond}) - \mathbf{H}(\hat{\mathbf{S}}_{\diamond}) = \sum_{k=0}^{K} h_k (\hat{\mathbf{S}}_{\diamond}^k - \mathbf{S}_{\diamond}^k)$$
(24)

Leveraging the product GSO expansion (23) and the perturbation model $\hat{\mathbf{S}} = \mathbf{S} + (\mathbf{SE} + \mathbf{ES})$ [cf. (13)] we can write the *k*-th power of the perturbed product graph GSO as

$$\hat{\mathbf{S}}^{k}_{\diamond} = (\mathbf{S}_{T0} \otimes \mathbf{I}_{N} + \mathbf{S}_{T1} \otimes (\mathbf{S} + (\mathbf{SE} + \mathbf{ES})))^{k}$$

$$= (\mathbf{S}_{\diamond} + (\mathbf{S}_{T1} \otimes (\mathbf{SE} + \mathbf{ES})))^{k}$$

$$= \mathbf{S}^{k}_{\diamond} + \sum_{r=0}^{k-1} \mathbf{S}^{r}_{\diamond} (\mathbf{S}_{T1} \otimes (\mathbf{SE} + \mathbf{ES})) \mathbf{S}^{k-r-1}_{\diamond} + \mathbf{D},$$
(25)

where we applied the first-order Taylor expansion in the third line. Matrix **D** contains all terms of order $\mathcal{O}(\epsilon^2)$ and can be ignored.

539 Substituting then (25) into (24), we get

$$\mathbf{H}(\mathbf{S}_{\diamond}) - \mathbf{H}(\hat{\mathbf{S}}_{\diamond}) = \sum_{k=0}^{K} h_k \sum_{r=0}^{k-1} \mathbf{S}_{\diamond}^r (\mathbf{S}_{T1} \otimes (\mathbf{SE} + \mathbf{ES})) \mathbf{S}_{\diamond}^{k-r-1}.$$
 (26)

⁵⁴⁰ Upon applying the filters to an input \mathbf{x}_{\diamond} we get the output difference $\mathbf{y}_{\diamond} - \hat{\mathbf{y}}_{\diamond} = (\mathbf{H}(\mathbf{S}_{\diamond}) - \mathbf{H}(\hat{\mathbf{S}}_{\diamond}))\mathbf{x}_{\diamond}$. ⁵⁴¹ Substituting into this the graph-time Fourier expansion of the input

$$\mathbf{x}_{\diamond} = \sum_{t=1}^{T} \sum_{n=1}^{N} \tilde{x}_{(n,t)} (\mathbf{v}_{T,t} \otimes \mathbf{v}_n)$$
(27)

with $\tilde{x}_{(n,t)}$ the (n,t)-th Fourier coefficients and $(\mathbf{v}_{T,t}, \mathbf{v}_n)$ the eigenvector pair for the temporal and spatial GSOs [cf. Sec. 3.1], we can write the output difference as

$$\mathbf{y}_{\diamond} - \hat{\mathbf{y}}_{\diamond} = \sum_{t=1}^{T} \sum_{n=1}^{N} \tilde{x}_{(n,t)} \sum_{k=0}^{K} h_k \sum_{r=0}^{k-1} \mathbf{S}_{\diamond}^r (\mathbf{S}_{T1} \otimes (\mathbf{SE} + \mathbf{ES})) \mathbf{S}_{\diamond}^{k-r-1} (\mathbf{v}_{T,t} \otimes \mathbf{v}_n).$$
(28)

544 Since $(\mathbf{v}_{T,t} \otimes \mathbf{v}_n)$ is an eigenvector of \mathbf{S}_\diamond , we have

$$\mathbf{S}^{k-r-1}_{\diamond}(\mathbf{v}_{T,t}\otimes\mathbf{v}_n) = \lambda^{k-r-1}_{\diamond,(n,t)}(\mathbf{v}_{T,t}\otimes\mathbf{v}_n)$$
(29)

⁵⁴⁵ which by substituting to (28) yields

$$\mathbf{y}_{\diamond} - \hat{\mathbf{y}}_{\diamond} = \sum_{t=1}^{T} \sum_{n=1}^{N} \tilde{x}_{(n,t)} \sum_{k=0}^{K} h_k \sum_{r=0}^{k-1} \lambda_{\diamond,(n,t)}^{k-r-1} \mathbf{S}_{\diamond}^r (\mathbf{S}_{T1} \otimes (\mathbf{SE} + \mathbf{ES})) (\mathbf{v}_{T,t} \otimes \mathbf{v}_n)$$
(30)

where $\lambda_{\diamond,(n,t)}$ is the eigenvalue of the product graph GSO S_{\diamond} for indices (n, t). Leveraging mixed product property of Kronecker product² allows us to rewrite (30) as

$$\mathbf{y}_{\diamond} - \hat{\mathbf{y}}_{\diamond} = \sum_{t=1}^{T} \sum_{n=1}^{N} \tilde{x}_{(n,t)} \sum_{k=0}^{K} h_k \sum_{r=0}^{k-1} \lambda_{\diamond,(n,t)}^{k-r-1} \mathbf{S}_{\diamond}^r (\mathbf{S}_{T1} \mathbf{v}_{T,t} \otimes (\mathbf{SE} + \mathbf{ES}) \mathbf{v}_n).$$
(31)

548 Replacing $\mathbf{S}_{T1} = s_{01}\mathbf{I}_T + s_{11}\mathbf{S}_T$ leads to

$$\hat{\mathbf{y}}_{\diamond} - \mathbf{y}_{\diamond} = \sum_{t=1}^{T} \sum_{n=1}^{N} (s_{01} + s_{11}\lambda_{T,t}) \tilde{x}_{(n,t)} \sum_{k=0}^{K} h_k \sum_{r=0}^{k-1} \lambda_{\diamond,(n,t)}^{k-r-1} \mathbf{S}_{\diamond}^{r} (\mathbf{v}_{T,t} \otimes (\mathbf{SE} + \mathbf{ES}) \mathbf{v}_n).$$
(32)

549 Applying Lemma 1 results in

$$\hat{\mathbf{y}}_{\diamond} - \mathbf{y}_{\diamond} = \sum_{t=1}^{T} \sum_{n=1}^{N} (s_{01} + s_{11}\lambda_{T,t}) \tilde{x}_{(n,t)} \sum_{k=0}^{K} h_k \sum_{r=0}^{k-1} \lambda_{\diamond,(n,t)}^{k-r-1} \mathbf{S}_{\diamond}^r (\mathbf{v}_{T,t} \otimes (\mathbf{S} + \lambda_n \mathbf{I}_N) (\underbrace{m_n \mathbf{v}_n}_{\text{term 1}} + \underbrace{\mathbf{E}_U \mathbf{v}_n}_{\text{term 2}})),$$
(33)

- ⁵⁵⁰ which leaves us with two terms that shall be discussed separately.
- 551 For the first term, we have

$$\mathbf{t}_{1} = \sum_{t=1}^{T} \sum_{n=1}^{N} 2\lambda_{n} m_{n} (s_{01} + s_{11}\lambda_{T,t}) \tilde{x}_{(n,t)} \sum_{k=0}^{K} h_{k} \sum_{r=0}^{k-1} \lambda_{\diamond,(n,t)}^{k-r-1} \mathbf{S}_{\diamond}^{r} (\mathbf{v}_{T,t} \otimes \mathbf{v}_{n}).$$
(34)

By exploiting eigenvector property $\mathbf{S}_{\diamond}^{r}(\mathbf{v}_{T,t}\otimes\mathbf{v}_{n}) = \lambda_{\diamond,(n,t)}^{r}(\mathbf{v}_{T,t}\otimes\mathbf{v}_{n})$ we can rewrite (34) into

$$\mathbf{t}_{1} = \sum_{t=1}^{T} \sum_{n=1}^{N} 2\lambda_{n} m_{n} (s_{01} + s_{11}\lambda_{T,t}) \tilde{x}_{(n,t)} \sum_{k=0}^{K} kh_{k} \lambda_{\diamond,(n,t)}^{k-1} (\mathbf{v}_{T,t} \otimes \mathbf{v}_{n}).$$
(35)

553 Applying Lemma 2 leads to

$$\mathbf{t}_1 = \sum_{t=1}^T \sum_{n=1}^N 2m_n \tilde{x}_{(n,t)} \lambda_n \frac{\partial h(\lambda_{\diamond,(n,t)})}{\partial \lambda_n} (\mathbf{v}_{T,t} \otimes \mathbf{v}_n).$$
(36)

554 For the second term, we have

$$\mathbf{t}_{2} = \sum_{t=1}^{T} \sum_{n=1}^{N} (s_{01} + s_{11}\lambda_{T,t}) \tilde{x}_{(n,t)} \sum_{k=0}^{K} h_{k} \sum_{r=0}^{k-r-1} \mathbf{S}_{\diamond,(n,t)}^{r} \mathbf{S}_{\diamond}^{r} (\mathbf{v}_{T,t} \otimes (\mathbf{S} + \lambda_{n} \mathbf{I}_{N}) \mathbf{E}_{U} \mathbf{v}_{n}).$$
(37)
$$\overline{(A \otimes B)(C \otimes D) = AC \otimes BD}$$

⁵⁵⁵ By substituting the eigendecomposition $\mathbf{S}^r_\diamond = (\mathbf{V}_T \otimes \mathbf{V}) \mathbf{\Lambda}^r_\diamond (\mathbf{V}_T \otimes \mathbf{V})^{\mathsf{H}}$ we get

$$\mathbf{t}_{2} = \sum_{t=1}^{T} \sum_{n=1}^{N} \tilde{x}_{(n,t)} (\mathbf{V}_{T} \otimes \mathbf{V}) \operatorname{diag}(\mathbf{g}_{(n,t)}) (\mathbf{V}_{T} \otimes \mathbf{V})^{\mathsf{H}} (\mathbf{v}_{T,t} \otimes \mathbf{E}_{U} \mathbf{v}_{n}).$$
(38)

where the entries of vectors $\mathbf{g}_{(n,t)} \in \mathbb{R}^{NT}$ for $n \in [N]$ and $t \in [T]$ are defined as

$$g_{(n,t)}(n',t') = (s_{01} + s_{11}\lambda_{T,t})(\lambda_n + \lambda_{n'})\sum_{k=0}^{k} h_k \sum_{r=0}^{k-1} \lambda_{\diamond,(n,t)}^{k-r-1} \lambda_{\diamond,(n',t')}^{r}$$

$$= \begin{cases} 2\lambda_n \frac{\partial h(\lambda_{\diamond,(n,t)})}{\partial \lambda_n}; & (n,t) = (n',t') \\ (s_{01} + s_{11}\lambda_{T,t})(h(\lambda_{\diamond,(n,t)}) - h(\lambda_{\diamond,(n',t')}))\frac{\lambda_n + \lambda_{n'}}{\lambda_n - \lambda_{n'}}; & (n,t) \neq (n',t') \end{cases}$$
(39)

With this in place, we now upper bound the two-norm of the difference $\mathbf{y}_{\diamond} - \hat{\mathbf{y}}_{\diamond} = \mathbf{t}_1 + \mathbf{t}_2$ by bounding each of the terms \mathbf{t}_1 and \mathbf{t}_2 separately. From $\|\mathbf{E}\| \le \epsilon$, we have that $|m_n| \le \epsilon$. Also from

the integral Lipschitz property of the filter [cf. Def. 1]. Using these two into (36), we can upper

bound the norm of term \mathbf{t}_1 as

$$\|\mathbf{t}_1\|_2 \le 2\epsilon C \sum_{t=1}^T \sum_{n=1}^N \tilde{x}_{(n,t)}(\mathbf{v}_{T,t} \otimes \mathbf{v}_n) \le 2\epsilon C \|\mathbf{x}_{\diamond}\|_2, \tag{40}$$

where the second inequality holds due to Fourier transform definition (27).

Moving on to \mathbf{t}_2 , we use mixed product property as $\mathbf{v}_{T,t} \otimes \mathbf{E}_U \mathbf{v}_n = (\mathbf{I}_T \otimes \mathbf{E}_U)(\mathbf{v}_{T,t} \otimes \mathbf{v}_n)$ and operator norms in (38) to obtain an upper bound as

$$\|\mathbf{t}_{2}\|_{2} \leq \sum_{t=1}^{T} \sum_{n=1}^{N} |\tilde{x}_{(n,t)}| \| (\mathbf{V}_{T} \otimes \mathbf{V}) \| \| \operatorname{diag}(\mathbf{g}_{(n,t)}) \| \| (\mathbf{V}_{T} \otimes \mathbf{V})^{\mathsf{H}} \| \| \mathbf{I}_{T} \otimes \mathbf{E}_{U} \| \| \mathbf{v}_{T,t} \otimes \mathbf{v}_{n} \|_{2}.$$
(41)

From the integral Lipschitz property we can bound $\|\text{diag}(\mathbf{g}_{(n,t)})\| \le 2C(s_{01} + s_{11}\lambda_{T,max})$ in (39) where $\lambda_{T,max}$ is a temporal eigenvalue with the largest absolute value. As $\mathbf{V}_T \otimes \mathbf{V}$ is an orthonormal bases, its operator norm is $\|\mathbf{V}_T \otimes \mathbf{V}\| = 1$, and l_2 -norm of the eigenvectors is $\|\mathbf{v}_{T,t} \otimes \mathbf{v}_n\|_2 = 1$. Lemma 1 states that $\|\mathbf{E}\| \le \epsilon \delta$ which leads to $\|\mathbf{I}_T \otimes \mathbf{E}_U\| \le \epsilon \delta$. Finally, l_1 -norm can be bounded by $\sum_{t=1}^T \sum_{n=1}^N |\tilde{x}_{(n,t)}| = \|\tilde{\mathbf{x}}\|_1 \le \sqrt{NT} \|\tilde{\mathbf{x}}\|_2 = \sqrt{NT} \|\mathbf{x}_{\diamond}\|_2$. Considering all the abovementioned bounds and replacing them in (41) yields

$$\|\mathbf{t}_2\|_2 \le 2(s_{01} + s_{11}\lambda_{T,max})\epsilon C\delta\sqrt{NT}\|\mathbf{x}_{\diamond}\|_2.$$

$$\tag{42}$$

570 Finally, based on the triangle inequality the GTConv filter difference is

$$\|\mathbf{H}(\mathbf{S}_{\diamond}) - \mathbf{H}(\hat{\mathbf{S}}_{\diamond})\| \le 2(s_{01} + s_{11}\lambda_{T,max})\epsilon C(1 + \delta\sqrt{NT}) = \epsilon\Delta.$$
(43)

571 Encoder stability.

⁵⁷² Consider the encoder contains L_e layer each having F_ℓ features and r sampling rate. We are interested ⁵⁷³ in the output difference of the encoder

$$\|\operatorname{ENC}(\mathbf{x}_{\diamond}, \mathbf{S}, \mathbf{S}_{T}) - \operatorname{ENC}(\mathbf{x}_{\diamond}, \hat{\mathbf{S}}, \mathbf{S}_{T})\|_{2}^{2} = \sum_{f=1}^{F_{L_{e}}} \|\mathbf{x}_{\diamond, L_{e}}^{f} - \hat{\mathbf{x}}_{\diamond, L_{e}}^{f}\|_{2}^{2}.$$
 (44)

To ease exposition, we denote $\mathbf{H} := \mathbf{H}(\mathbf{S})$ and $\hat{\mathbf{H}} := \mathbf{H}(\hat{\mathbf{S}})$. For the f-th output encoder feature we have

$$\|\mathbf{x}_{\diamond,L_{e}}^{f} - \hat{\mathbf{x}}_{\diamond,L_{e}}^{f}\|_{2} = \left\|\sigma\left(\sum_{g=1}^{F_{L_{e}-1}} S_{r}(\mathbf{H}_{L_{e}}^{fg}\mathbf{x}_{\diamond,L_{e}-1}^{g})\right) - \sigma\left(\sum_{g=1}^{F_{L_{e}-1}} S_{r}(\hat{\mathbf{H}}_{L_{e}}^{fg}\hat{\mathbf{x}}_{\diamond,L_{e}-1}^{g})\right)\right\|_{2}$$
(45)

where $S_r(\cdot)$ is the sampling operator with rate r, i.e., simple $SUM(\cdot)$ function without any aggregative T is the sampling operator with rate r, i.e., simple $SUM(\cdot)$ function without any aggregative T is the sampling operator with rate r, i.e., simple $SUM(\cdot)$ function without any aggregative T is the sampling operator with rate r, i.e., simple $SUM(\cdot)$ function without any aggregative T is the sampling operator with rate r, i.e., simple $SUM(\cdot)$ function without any aggregative T is the sampling operator with rate r, i.e., simple $SUM(\cdot)$ function without any aggregative T is the sampling operator $SUM(\cdot)$ is the sampling operator T is the sampling operat

tion. The downsampling reduces the norm of each time series by a factor $1/\sqrt{r}$, so $\|\mathbf{y}_{\diamond,L_e}\|_2$ will be

reduced by $1/\sqrt{r}$. As non-linearity is 1-Lipschitz, i.e., $|\sigma(a) - \sigma(b)| \le |a - b|$, we can conclude the following inequality from (45) by use of triangular inequality

$$\|\mathbf{x}_{\diamond,L_{e}}^{f} - \hat{\mathbf{x}}_{\diamond,L_{e}}^{f}\|_{2} \leq \frac{1}{\sqrt{r}} \sum_{g=1}^{F_{L_{e}-1}} \left\|\mathbf{H}_{L_{e}}^{fg} \mathbf{x}_{\diamond,L_{e}-1}^{g} - \hat{\mathbf{H}}_{L_{e}}^{fg} \hat{\mathbf{x}}_{\diamond,L_{e}-1}^{g}\right\|_{2}.$$
 (46)

We add and subtract $\hat{\mathbf{H}}_{L}^{fg} \mathbf{x}_{\diamond,L-1}^{g}$ inside the l_2 -norm and use the triangular inequality once again for each of the input features g to get

$$\begin{aligned} \left\| \mathbf{H}_{L_{e}}^{fg} \mathbf{x}_{\diamond,L_{e}-1}^{g} - \hat{\mathbf{H}}_{L_{e}}^{fg} \hat{\mathbf{x}}_{\diamond,L_{e}-1}^{g} \right\|_{2} &\leq \| (\mathbf{H}_{L_{e}}^{fg} - \hat{\mathbf{H}}_{L_{e}}^{fg}) \mathbf{x}_{\diamond,L_{e}-1}^{g} \|_{2} + \| \hat{\mathbf{H}}_{L_{e}}^{fg} (\mathbf{x}_{\diamond,L_{e}-1}^{g} - \hat{\mathbf{x}}_{\diamond,L_{e}-1}^{g}) \|_{2} \\ &\leq \| \mathbf{H}_{L_{e}}^{fg} - \hat{\mathbf{H}}_{L_{e}}^{fg} \| \| \mathbf{x}_{\diamond,L_{e}-1}^{g} \|_{2} + \| \hat{\mathbf{H}}_{L_{e}}^{fg} \| \| \mathbf{x}_{\diamond,L_{e}-1}^{g} - \hat{\mathbf{x}}_{\diamond,L_{e}-1}^{g} \|_{2} \end{aligned}$$

$$(47)$$

The stability of GTConv filter in (43) provides an upper bound for the first term as $\|\mathbf{H}_{L_e}^{fg} - \hat{\mathbf{H}}_{L_e}^{fg}\| \le \epsilon \Delta$ which is applicable for all the layers. Note that Δ depends on temporal graph size, so it is different in each layer due to the downsampling. However, we assume the largest temporal size T so the inequality holds for all the layers³. The second term is bounded by spectral normalization assumption $\|\mathbf{H}_{L_e}^{fg}\| \le 1$ [cf. Def. 2]. Leveraging these bounds and replacing in (46) we get

$$\|\mathbf{x}_{\diamond,L_{e}}^{f} - \hat{\mathbf{x}}_{\diamond,L_{e}}^{f}\|_{2} \leq \frac{1}{\sqrt{r}} \sum_{g=1}^{F_{L_{e}-1}} \epsilon \Delta \|\mathbf{x}_{\diamond,L_{e}-1}^{g}\|_{2} + \|\mathbf{x}_{\diamond,L_{e}-1}^{g} - \hat{\mathbf{x}}_{\diamond,L_{e}-1}^{g}\|_{2}.$$
(48)

This equation defines a recursion among the encoder layers with initial condition $\mathbf{x}_{\diamond,0}^g = \hat{\mathbf{x}}_{\diamond,0}^g := \mathbf{x}_{\diamond}^g$ for all the input features. So for the ℓ -th layer, we can write

$$\|\mathbf{x}_{\diamond,\ell}^{f} - \hat{\mathbf{x}}_{\diamond,\ell}^{f}\|_{2} \leq \frac{1}{\sqrt{r}} \sum_{g=1}^{F_{\ell-1}} \epsilon \Delta \|\mathbf{x}_{\diamond,\ell-1}^{g}\|_{2} + \|\mathbf{x}_{\diamond,\ell-1}^{g} - \hat{\mathbf{x}}_{\diamond,\ell-1}^{g}\|_{2}.$$
(49)

To solve this recursive inequality, we first upper bound $\|\mathbf{x}_{\diamond,\ell}^{f}\|_{2}$ as

$$\|\mathbf{x}_{\diamond,\ell}^{f}\|_{2} \leq \frac{1}{\sqrt{r}} \sum_{g=1}^{F_{\ell-1}} \|\mathbf{H}_{\ell}^{fg} \mathbf{x}_{\diamond,\ell-1}^{g}\|_{2} \leq \frac{1}{\sqrt{r}} \sum_{g=1}^{F_{\ell-1}} \|\mathbf{x}_{\diamond,\ell-1}^{g}\|_{2},$$
(50)

where the last inequality is due to the assumption $\|\mathbf{H}_{\ell}^{fg}\| \leq 1$ [Def. 2]. Solving this recursion leads to

$$\|\mathbf{x}_{\diamond,\ell}^{f}\|_{2} \leq \frac{1}{r^{l/2}} \prod_{i=1}^{\ell-1} F_{i} \sum_{g=1}^{F_{0}} \|\mathbf{x}_{\diamond}^{g}\|_{2} = r^{-\ell/2} \prod_{i=1}^{\ell-1} F_{i} \sum_{g=1}^{F_{0}} \|\mathbf{x}_{\diamond}^{g}\|_{2}.$$
 (51)

Replacing (51) in (49) and solving the recursion considering the initial conditions we get

$$\|\mathbf{x}_{\diamond,\ell}^f - \hat{\mathbf{x}}_{\diamond,\ell}^f\|_2 \le r^{-\ell/2} \epsilon \Delta \ell \prod_{i=1}^{\ell-1} F_i \sum_{g=1}^{F_0} \|\mathbf{x}_{\diamond}^g\|_2.$$
(52)

Setting $\ell = L_e$ in (52) and replacing it in (44) yields to

$$\|\operatorname{ENC}(\mathbf{x}_{\diamond}, \mathbf{S}, \mathbf{S}_{T}) - \operatorname{ENC}(\mathbf{x}_{\diamond}, \hat{\mathbf{S}}, \mathbf{S}_{T})\|_{F} \le L_{e} r^{-L_{e}/2} \epsilon \Delta \sqrt{F_{L_{e}}} \prod_{n=1}^{L_{e}-1} F_{n} \sum_{g=1}^{F_{0}} \|\mathbf{x}_{\diamond}^{g}\|_{2}.$$
 (53)

593 GTConv-AE stability.

Let $\mathbf{Z}_{\diamond} = \text{ENC}(\mathbf{x}_{\diamond}, \mathbf{S}, \mathbf{S}_T)$ be the input of the decoder and $\mathbf{z}_{\diamond, L_d} = \text{DEC}(\mathbf{Z}_{\diamond}, \mathbf{S}, \mathbf{S}_T)$ its output. To prove GTConvAE stability, we need to bound

$$\|\text{DEC}(\mathbf{Z}_{\diamond}, \mathbf{S}, \mathbf{S}_{T}) - \text{DEC}(\mathbf{Z}_{\diamond}, \hat{\mathbf{S}}, \mathbf{S}_{T})\|_{2}^{2} = \sum_{f=1}^{F_{d, L_{d}}} \|\mathbf{z}_{\diamond, L_{d}}^{f} - \hat{\mathbf{z}}_{\diamond, L_{d}}^{f}\|_{2}^{2}.$$
 (54)

³It is possible to solve the recursive equation with Δ_T as a variable, but it leads to overcrowded multipliers in inequalities without carrying important information on the bound.

596 For each feature in the output we have

$$\|\mathbf{z}_{\diamond,L_{d}}^{f} - \hat{\mathbf{z}}_{\diamond,L_{d}}^{f}\|_{2} = \left\| \sigma \left(\sum_{g=1}^{F_{d,L_{d}-1}} U_{r}(\mathbf{H}_{L_{d}}^{fg} \mathbf{z}_{\diamond,L_{d}-1}^{g}) \right) - \sigma \left(\sum_{g=1}^{F_{d,L_{d}-1}} U_{r}(\hat{\mathbf{H}}_{L_{d}}^{fg} \hat{\mathbf{z}}_{\diamond,L_{d}-1}^{g}) \right) \right\|_{2}$$
(55)

where $U_r(\cdot)$ is an upsampling operator with rate r which insert zeros among the samples. The upsampling module leaves the l_2 -norm per time series unaffected and can be ignored. Given 1-Lipschitz continuity of activation function $\sigma(\cdot)$, the following inequality can be concluded from (55) using the triangular inequality

$$\|\mathbf{z}_{\diamond,L_{d}}^{f} - \hat{\mathbf{z}}_{\diamond,L_{d}}^{f}\|_{2} \leq \sum_{g=1}^{F_{d,L_{d}-1}} \left\|\mathbf{H}_{L_{d}}^{fg} \mathbf{z}_{\diamond,L_{d}-1}^{g} - \hat{\mathbf{H}}_{L_{d}}^{fg} \hat{\mathbf{z}}_{\diamond,L_{d}-1}^{g}\right\|_{2}.$$
(56)

Adding and subtracting $\hat{\mathbf{H}}_{L_d}^{fg} \mathbf{z}_{\diamond, L_d-1}^g$ in the norm and leveraging again the triangular inequality yields

$$\begin{aligned} \left\| \mathbf{H}_{L_{d}}^{fg} \mathbf{z}_{\diamond, L_{d}-1}^{g} - \hat{\mathbf{H}}_{L_{d}}^{fg} \hat{\mathbf{z}}_{\diamond, L_{d}-1}^{g} \right\|_{2} &\leq \| (\mathbf{H}_{L_{d}}^{fg} - \hat{\mathbf{H}}_{L_{d}}^{fg}) \mathbf{z}_{\diamond, L_{d}-1}^{g} \|_{2} + \| \hat{\mathbf{H}}_{L_{d}}^{fg} (\mathbf{z}_{\diamond, L_{d}-1}^{g} - \hat{\mathbf{z}}_{\diamond, L_{d}-1}^{g}) \|_{2} \\ &\leq \| \mathbf{H}_{L_{d}}^{fg} - \hat{\mathbf{H}}_{L_{d}}^{fg} \| \| \mathbf{z}_{\diamond, L_{d}-1}^{g} \|_{2} + \| \hat{\mathbf{H}}_{L_{d}}^{fg} \| \| \mathbf{x}_{\diamond, L_{d}-1}^{g} - \hat{\mathbf{z}}_{\diamond, L_{d}-1}^{g} \|_{2}, \end{aligned}$$

$$\tag{57}$$

for $g = 1, \ldots, F_{d,L_d-1}$. The first term is bounded by GTConv filters stability in (43) and the second

term is upper-bounded because filters are normalized $\|\mathbf{H}_{\ell}^{fg}\| \leq 1$ [cf. Def. 2]. Given these two bounds, (57) can be upper-bounded as

$$\|\mathbf{z}_{\diamond,L_{d}}^{f} - \hat{\mathbf{z}}_{\diamond,L_{d}}^{f}\|_{2} \leq \sum_{g=1}^{F_{d,L_{d}-1}} \epsilon \Delta \|\mathbf{z}_{\diamond,L_{d}-1}^{g}\|_{2} + \|\mathbf{z}_{\diamond,L_{d}-1}^{g} - \hat{\mathbf{z}}_{\diamond,L_{d}-1}^{g}\|_{2}.$$
 (58)

This allows defining a recursion for the generic layer ℓ as

$$\|\mathbf{z}_{\diamond,\ell}^{f} - \hat{\mathbf{z}}_{\diamond,\ell}^{f}\|_{2} \leq \sum_{g=1}^{F_{d,\ell-1}} \epsilon \Delta \|\mathbf{z}_{\diamond,\ell-1}^{g}\|_{2} + \|\mathbf{z}_{\diamond,\ell-1}^{g} - \hat{\mathbf{z}}_{\diamond,\ell-1}^{g}\|_{2}.$$
(59)

⁶⁰⁶ For the first term on the right hand-side of (59), we have

$$\|\mathbf{z}_{\diamond,\ell}^{f}\|_{2} \leq \sum_{g=1}^{F_{d,\ell-1}} \|\mathbf{H}_{\ell}^{fg} \mathbf{z}_{\diamond,\ell-1}^{g}\|_{2} \leq \sum_{g=1}^{F_{d,\ell-1}} \|\mathbf{z}_{\diamond,\ell-1}^{g}\|_{2} = \prod_{j=1}^{\ell-1} F_{d,j} \sum_{g=1}^{F_{d,0}} \|\mathbf{z}_{\diamond,0}^{g}\|_{2}$$
(60)

because $\|\mathbf{H}_{\ell}^{fg}\| \leq 1$ [cf. Def. 2]. Replacing (60) into (59) and evaluating it at $\ell = L_d$ brings the recursion to its initial conditions

$$\|\mathbf{z}_{\diamond,L_{d}}^{f} - \hat{\mathbf{z}}_{\diamond,L_{d}}^{f}\|_{2} \leq \epsilon \Delta L_{d} \prod_{j=1}^{L_{d}-1} F_{d,j} \sum_{g=1}^{F_{d,0}} \|\mathbf{z}_{\diamond,0}^{g}\|_{2} + \prod_{j=1}^{L_{d}-1} F_{d,j} \sum_{g=1}^{F_{d,0}} \|\mathbf{z}_{\diamond,0}^{g} - \hat{\mathbf{z}}_{\diamond,0}^{g}\|_{2}.$$
(61)

For initial conditions we have $\mathbf{Z}_{\diamond,0} = \mathbf{Z}_{\diamond}$, however, the error caused by spatial graph perturbation in the encoder appears here as an initial condition where $\|\mathbf{z}_{\diamond,0}^f - \hat{\mathbf{z}}_{\diamond,0}^f\|_2$ is bounded by the result in (53) for $f \in [F_{d,0}]$.

As the initial condition of the decoder states $\mathbf{Z}_{\diamond,0} = \mathbf{Z}_{\diamond} = \mathbf{X}_{\diamond,L}$, we can set $\ell = L$ in (51) to obtain

$$\|\mathbf{z}_{\diamond}^{f}\|_{2} \leq r^{-L_{e}/2} \prod_{i=1}^{L_{e}-1} F_{i} \sum_{g=1}^{F_{0}} \|\mathbf{x}_{\diamond}^{g}\|_{2}.$$
 (62)

Substituting encoder stability bound (53), to enforce the initial condition for $\sum_{g=1}^{F_{d,0}} \|\mathbf{z}_{\diamond,0}^g - \hat{\mathbf{z}}_{\diamond,0}^g\|_2$, and (62) into (61) results in

$$\|\mathbf{z}_{\diamond,L_{d}}^{f} - \hat{\mathbf{z}}_{\diamond,L_{d}}^{f}\|_{2} \leq L_{d}r^{-L_{e}/2}\epsilon\Delta F_{d,0}\prod_{i=1}^{L_{e}-1}F_{i}\prod_{j=1}^{L_{d}-1}F_{d,j}\sum_{g=1}^{F_{0}}\|\mathbf{x}_{\diamond}^{g}\|_{2} + L_{e}r^{-L_{e}/2}\epsilon\Delta F_{d,0}\prod_{i=1}^{L_{e}-1}F_{i}\prod_{j=1}^{L_{d}-1}F_{d,j}\sum_{g=1}^{F_{0}}\|\mathbf{x}_{\diamond}^{g}\|_{2}.$$
(63)

615 Calculating over all the output features completes the upper-bound as

$$\|\operatorname{GTConvAE}(\mathbf{x}_{\diamond}, \mathbf{S}, \mathbf{S}_{T}) - \operatorname{GTConvAE}(\mathbf{x}_{\diamond}, \mathbf{S}, \mathbf{S}_{T})\|_{2} \leq (L_{d} + L_{e})r^{-L_{e}/2}\epsilon\Delta\sqrt{F_{d,L_{d}}}\prod_{i=1}^{L_{e}-1}F_{i}\prod_{j=0}^{L_{d}-1}F_{d,j}\sum_{g=1}^{F_{0}}\|\mathbf{x}_{\diamond}^{g}\|_{2}.$$
(64)

Assuming $F_0 = F_{d,L_d} = 1$ and $\{F_d, F\} \leq F_{max}$ completes the proof.

B Denoising solar irradiance time series

In this appendix we provide extra information on numerical experiment for denoising solar irradiance time series.

SNR: An error vector $\mathbf{e}_t \sim \mathcal{N}(0, L^{\dagger})$ is generated independently for each timestamp $t \in [T]$. Matrix L represents normalized Laplacian and \dagger stands for pseudo-inverse operation. This noise varies smoothly over spatial graph which makes it more difficult to detect. Assume noise matrix $\sigma \mathbf{E} = \sigma[\mathbf{e}_1, \dots, \mathbf{e}_T] \in \mathbb{R}^{N \times T}$, we define SNR as follow:

$$SNR = 20\log\frac{\|\mathbf{X}\|_F}{\sigma\|\mathbf{E}\|_F},\tag{65}$$

where σ is used to control SNR for the experiments.

Model parameters: The time window is searched over $T \in \{2, ..., 8\}$. The number of layers for both encoder and decoder are selected from $L_e = L_d \in \{2,3\}$. The number of features for every layer are chosen from $F \in 32, 16, 8, 4, 2$. The filter order is evaluated on $K \in \{2, 3, 4, 5\}$. The sampling is searched over $r \in \{1, 2, 3, 4\}$. All the aggregation function have been tested. Finally, the regularizer weight initially selected from logarithmic interval $\rho \in \{10^{-2}, ..., 10^{2}\}$ and fine-tuned around optimum value.

631 C Anomaly detection in water networks

In this appendix we provide extra information on numerical experiments for anomaly detection in water networks.

Model parameters: The model parameters are evaluated and fine-tuned by sliding window backtesting. The time window is searched over $T \in \{2, ..., 8\}$. The number of layers for both encoder and decoder are selected from $L_e = L_d \in \{2, 3\}$. The number of features for every layer are chosen from $F \in 128, 64, 32, 16, 8, 4, 2$. The filter order is evaluated on $K \in \{2, 3, 4, 5\}$. The sampling is searched over $r \in \{1, 2, 3\}$. All the aggregation functions have been tested. Finally, the regularizer weight initially selected from logarithmic interval $\rho \in \{10^{-2}, ..., 10^{2}\}$ and fine-tuned around optimum value.
