

Table 1: The data size and query speed on ROxford + R1M.

(a) Average data size per image. Note that the local descriptors are not required in the online retrieval.

global feature	local features' matching information	local features
8192 B	2678 B	1040000 B

(b) Breakdown of average time per query.

initial search	hypergraph propagation	uncertainty calculation	spatial verification
0.62 s	1.07 s	0.0003 s	41.12 s

1 Appendix A: Data size and speed

2 To construct hypergraph at query time, we need to record the spatial matching information for each
 3 image and its k-nearest neighbors. Instead of pre-computing and recording the homography matrices
 4 as described in the Section 3, we directly record matched local feature pairs. More specifically, we
 5 conduct spatial verification between each database image and its K-nearest neighbors, then record the
 6 local features' locations and a set of index tuples pointing to matched local-feature pairs.

7 Table 1 (a) summarizes the average size of the global feature, local features and the local features'
 8 matching information per image when conducting the experiment on ROxford + R1M. Note that the
 9 online retrieval only uses the locations of local features, therefore we do not need to load the local
 10 features into memory. The size of local features' matching information is less than that of the global
 11 feature.

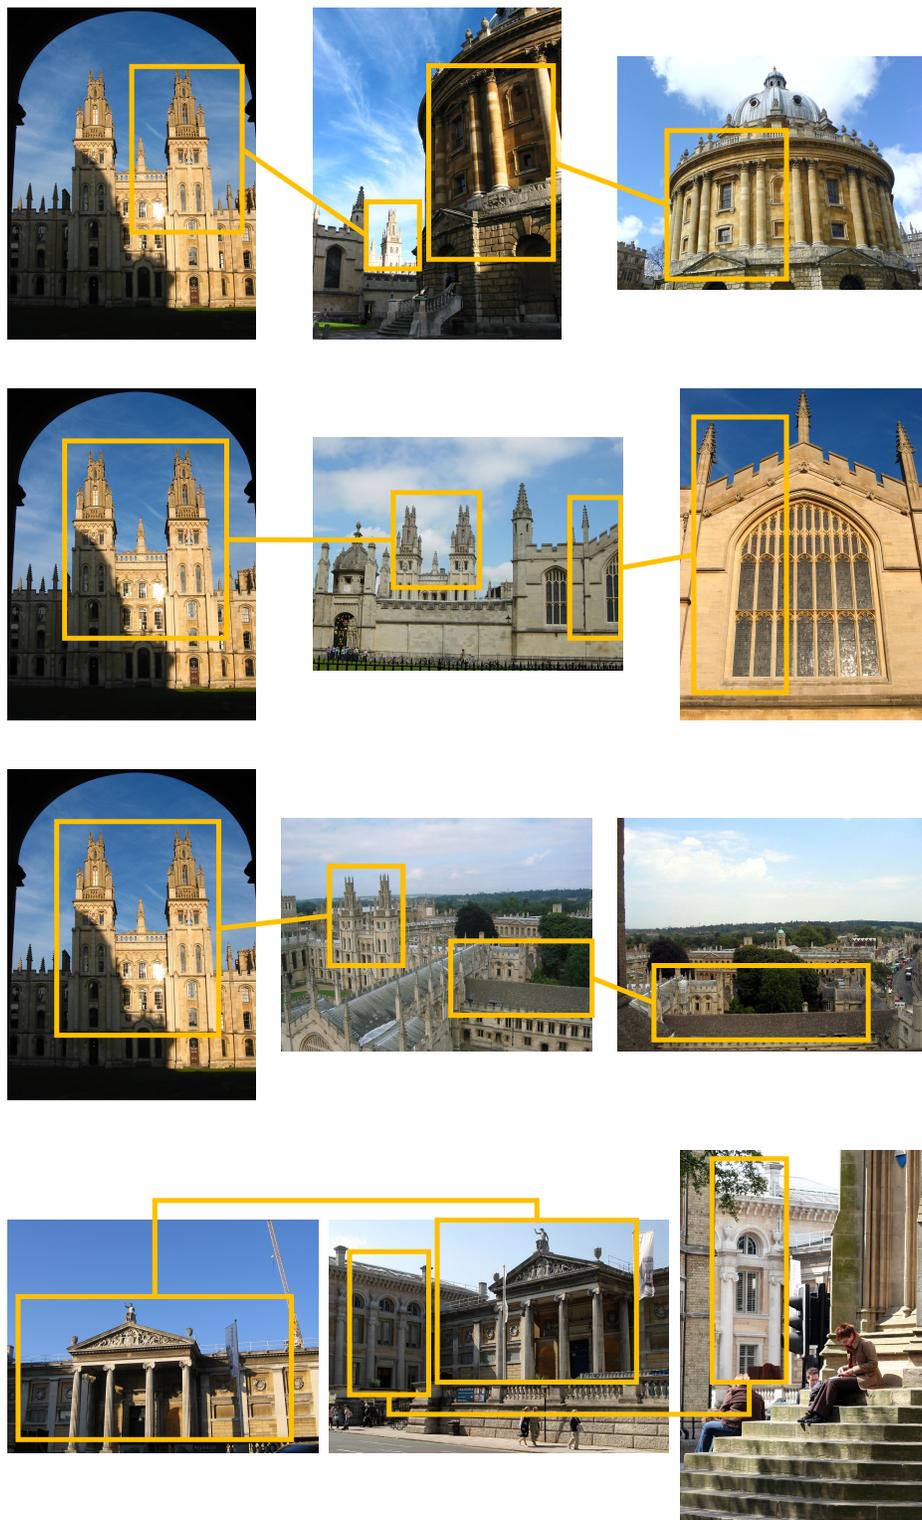

12 Table 1 (2) shows the breakdown of average time per query during experiment on ROxford + R1M.
 13 The average time of hypergraph propagation for each query is 1.07 s while initial search is 0.62 s. We
 14 think this overhead is acceptable. In addition, the spatial verification takes much longer time than
 15 other parts. This verifies the efficiency of our community selection approach, which fastly calculates
 16 the uncertainty to skip the unnecessary spatial verification for good initial search result.

17 Appendix B: Visualization of hypergraph propagation

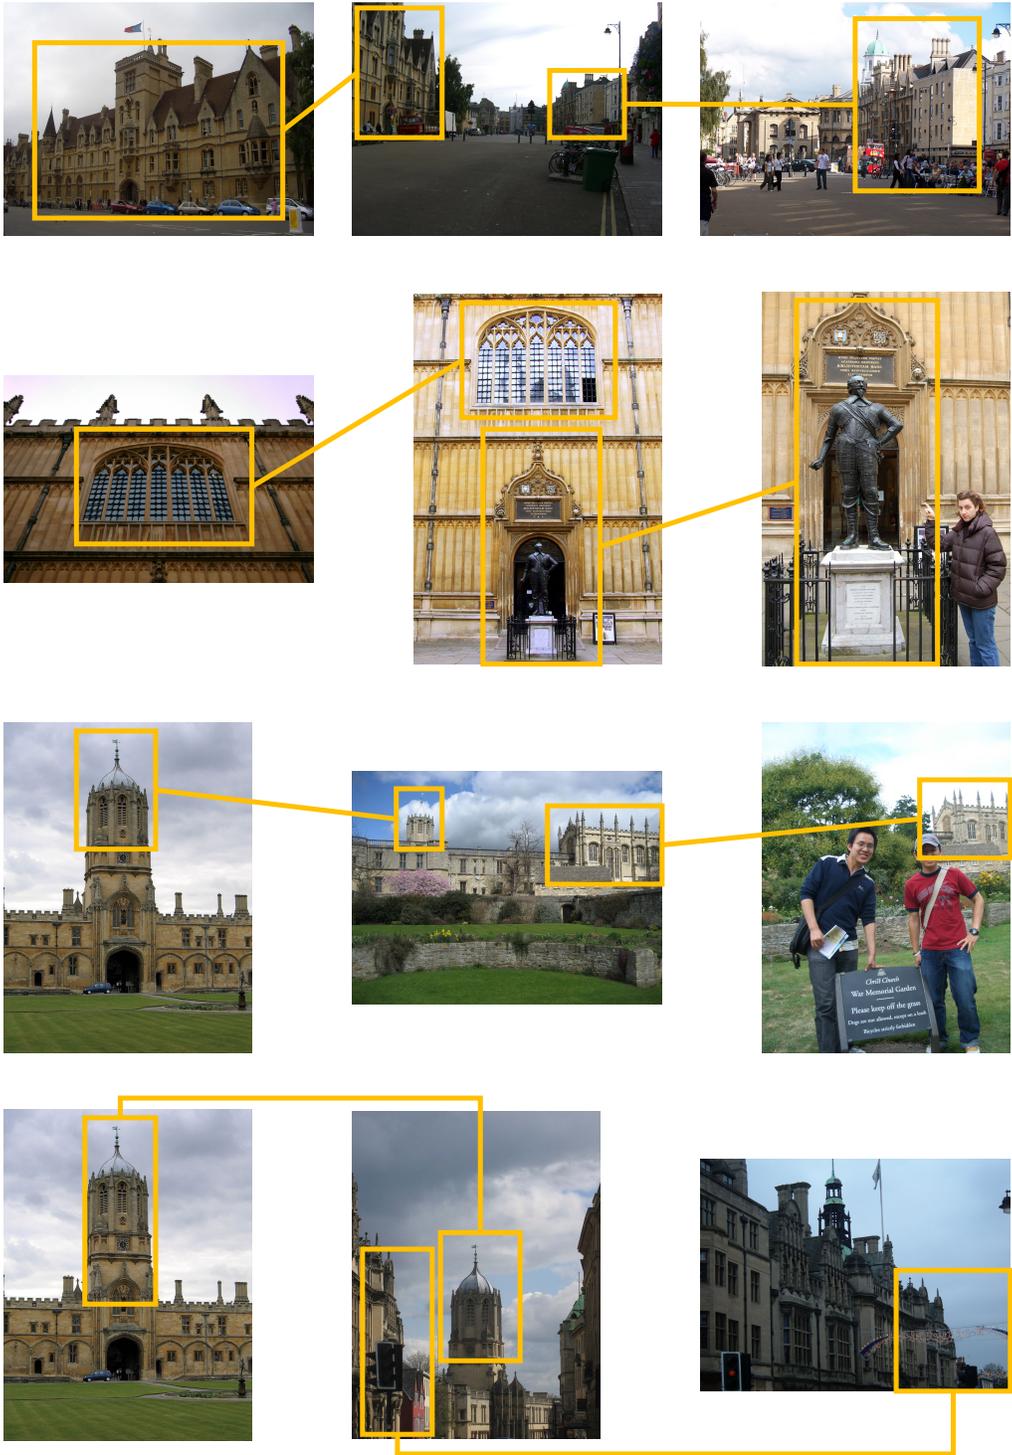

18 We visualize the benefit of hypergraph propagation with actual queries in Figure ???. The yellow
 19 boxes represent the correctly matched regions through hyperedges. In each row, the first image
 20 and the third image are wrongly connected through the second image in the ordinary graph. Our
 21 hypergraph propagation mechanism correctly separates these wrong connections by solving the
 22 ambiguity problem of propagation.

23 Appendix C: Illustration of hypergraph propagation

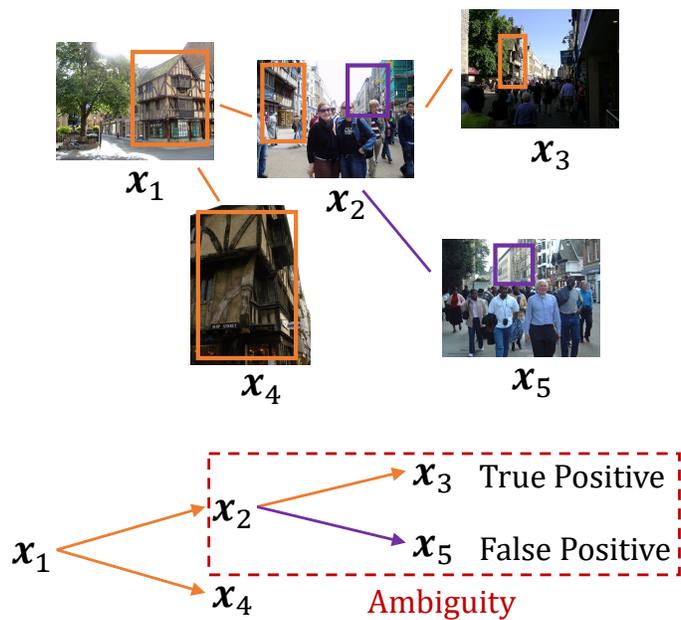

24 Appendix-Figure 2 shows a large version of Figure 1 in the paper. In Appendix-Figure 2, a) shows a
 25 part of an ordinary graph with scalar-weighted, i.e., similarity, edges. Orange frames are the common
 26 visible regions among images \mathbf{x}_1 , \mathbf{x}_2 , \mathbf{x}_3 , and \mathbf{x}_4 . Purple frames are the common visible regions
 27 between images \mathbf{x}_2 and \mathbf{x}_5 . \mathbf{x}_3 and \mathbf{x}_5 are close neighbors to image \mathbf{x}_2 . While \mathbf{x}_3 is related to \mathbf{x}_1
 28 by sharing the orange frame, \mathbf{x}_5 is not. Utilizing scalar-weighted edges cannot propagate the query
 29 in the ordinary graph without this ambiguity issue. b) shows the corresponding hypergraph of a).
 30 Inter-image hyperedges \mathbf{e}_s^1 are shown in yellow, intra-image hyperedges \mathbf{e}_k^2 are in blue, and local
 31 features \mathbf{y}_n are in green. A hypergraph path connects local features from \mathbf{y}_1 to \mathbf{y}_9 in \mathbf{x}_1 and \mathbf{x}_3 , but
 32 no path connects local features in \mathbf{x}_1 and \mathbf{x}_5 .
