

SELF-ADVERSARIAL LEARNING WITH COMPARATIVE DISCRIMINATION FOR TEXT GENERATION

Anonymous authors

Paper under double-blind review

ABSTRACT

Conventional Generative Adversarial Networks (GANs) for text generation tend to have issues of reward sparsity and mode collapse that affect the quality and diversity of generated samples. To address the issues, we propose a novel self-adversarial learning (SAL) paradigm for improving GANs' performance in text generation. In contrast to standard GANs that use a binary classifier as its discriminator to predict whether a sample is real or generated, SAL employs a comparative discriminator which is a pairwise classifier for comparing the text quality between a pair of samples. During training, SAL rewards the generator when its currently generated sentence is found to be better than its previously generated samples. This self-improvement reward mechanism allows the model to receive credits more easily and avoid collapsing towards the limited number of real samples, which not only helps alleviate the reward sparsity issue but also reduces the risk of mode collapse. Experiments on text generation benchmark datasets show that our proposed approach substantially improves both the quality and the diversity, and yields more stable performance compared to the previous GANs for text generation.

1 INTRODUCTION

Generative Adversarial Networks (Goodfellow et al., 2014) (GANs) have achieved tremendous success for image generation and received much attention in computer vision. For text generation, however, the performance of GANs is severely limited due to reward sparsity and mode collapse: reward sparsity refers to the difficulty for the generator to receive reward signals when its generated samples can hardly fool the discriminator that is much easier to train; while mode collapse refers to the phenomenon that the generator only learns limited patterns from the real data. As a result, both the quality and diversity of generated text samples are limited.

To address the above issues, we propose a novel self-adversarial learning (SAL) paradigm for improving adversarial text generation. In contrast to standard GANs (Figure 1(a)) that use a binary classifier as its discriminator to predict whether a sample is real or generated, SAL employs a comparative discriminator which is a pairwise classifier assessing whether the currently generated sample is better than its previously generated one, as shown in Figure 1(b). During training, SAL rewards the generator when its currently generated samples are found to be better than its previously generated samples. In the earlier training stage when the quality of generated samples is far below the real data, this self-improvement reward mechanism makes it easier for the generator to receive non-sparse rewards with informative learning signals, effectively alleviating the reward sparsity issue; while in the later training stage, SAL can prevent a sample from keeping receiving high reward as the self-improvement for a popular mode will become more and more difficult, and therefore help the generator avoid collapsing toward the limited patterns of real data.

We comprehensively evaluate the proposed self-adversarial learning paradigm in both synthetic data and real data on the text generation benchmark platform (Zhu et al., 2018). Compared to the previous approaches for adversarial text generation (Yu et al., 2017; Che et al., 2017; Lin et al., 2017), our approach shows a substantial improvement in terms of both the quality and the diversity of generated samples as well as better performance stability in adversarial learning.

Figure 1: (a) Conventional adversarial learning that uses a binary real/fake classifier as its discriminator; (b): Self-adversarial learning that employs a comparative discriminator to compare the currently generated sample to its previously generated samples for obtaining rewards through self-improvement.

2 BACKGROUND: ADVERSARIAL TEXT GENERATION

Adversarial text generation has drawn much attention in recent years due to its advantages (e.g., sequence-level guidance without the exposure bias issue (Bengio et al., 2015)) over maximum likelihood estimation (MLE) for natural language generation. It formulates the learning process as a minimax game between a generator G_θ parameterized by θ and a discriminator D_ϕ parameterized by ϕ : the discriminator is trained to distinguish between the samples drawn from the real data distribution p_{data} and the samples generated by the generator; while the generator is trained to generate samples that can “fool” the discriminator. The adversarial learning objective of the generator and the discriminator can be formulated as:

$$\min_{\theta} \max_{\phi} \mathbb{E}_{\mathbf{x} \sim p_{data}} [\log D_{\phi}(\mathbf{x})] + \mathbb{E}_{\mathbf{z} \sim p_z} [\log(1 - D_{\phi}(G_{\theta}(\mathbf{z})))] \quad (1)$$

where \mathbf{x} is a sample from the read data, $G_{\theta}(\mathbf{z})$ is a sample generated by the generator with the initialization \mathbf{z} that is drawn from the noise distribution p_z (e.g., standard normal distribution).

While GANs have shown some promising results (Yu et al., 2017; Guo et al., 2018), there are two fundamental issues that impede their progress in text generation: (i) Reward sparsity, which is due to the fact that the discriminator tends to learn much better than the generator and thus easily recognizes generated samples as fake. In such cases, it will be difficult for the generator to receive rewards; (ii) Mode collapse, which arises from the intrinsic nature of GANs and leads the adversarial models to only learn the limited patterns from the real samples. These two issues limit the ability of GANs to generate high-quality and diverse text samples, which have not been well addressed yet.

3 SELF-ADVERSARIAL LEARNING

To address the aforementioned issues, we propose a novel self-adversarial learning (SAL) paradigm. Inspired by self-play (Silver et al., 2017; Rennie et al., 2017) in reinforcement learning, the core idea of SAL is to reward the generator if its currently generated sample is found to be better than its previously generated ones. Like AlphaGo (Silver et al., 2017), the generator in SAL struggles to learn to generate better samples than its previously generated samples for passing the “self-improvement” test by a comparative discriminator, which is a pairwise classifier trained to compare the quality of two samples, as Figure 1(b) shows.

Compared to conventional GANs (Figure 1(a)), SAL has the following advantages: First, in the earlier training stage when the quality of generated samples is far below the real data, the self-improvement reward mechanism of SAL allows the generator to receive informative learning signals more easily as it makes the assessment of sample quality better adapted to the current capability of the generator, making it less likely to suffer from the issue of reward sparsity; Second, in the later training stage when the generated samples’ quality is high, SAL can prevent a sample from keeping receiving high reward as it will become more and more difficult to pass the “self-improvement” test, thus reducing the risk of the generator collapsing towards limited patterns. The self-improvement mechanism and the ‘tie’ option in the comparative discriminator also provides a reasonable baseline which corresponds to cases where newly generated samples are found to be indistinguishable with previous ones, thus improving the training stability. We provide a more detailed qualitative analysis of why the proposed self-adversarial learning paradigm can alleviate these problems in Appendix.

Figure 2: The training process of the comparative discriminator.

3.1 COMPARATIVE DISCRIMINATOR

As introduced above, the core component for SAL is the comparative discriminator, which is a pairwise classifier comparing the quality of two samples. It learns a total order of sample quality and encodes the inductive bias that one sample is better ($>$), worse ($<$), or indistinguishable (\approx) in terms of its quality compared to the other. For a (text) sample, the comparative discriminator can offer more informative learning signals than the conventional binary (i.e., real/fake) classification based discriminator because the sample can receive multiple feedbacks from the comparative discriminator by comparing it with multiple other samples.

For training the comparative discriminator, we construct pairwise training examples from the real and generated samples, as Figure 2 shows. For a real sample s_+ and a generated sample s_- , we assign the label “better ($>$)” to the pair (s_+, s_-) and “worse ($<$)” to (s_-, s_+) . For two samples both from real data or from the generated samples, we assign the label “indistinguishable (\approx)” to such pairs (i.e., (s_+^i, s_+^j) and (s_-^i, s_-^j)). For a training set with n real samples and n generated samples, the comparative discrimination can construct $\binom{2n}{2}$ pairwise training examples, allowing to enhance the generalization ability of the comparative discriminator. In addition, to avoid the comparative discriminator from always recognizing two generated samples as equally bad and get zero reward, we construct weakly supervision examples by regarding samples generated during later stage of MLE training as pseudo-real samples and that generated in the earlier epochs as fake sentences. By additionally sampling these weakly supervision examples, the decision boundary of the comparative discriminator may be relaxed and allow the generator receive rewards more easily.

3.2 TRAINING

Before we formally introduce the training procedure for SAL, we first define the learning objective for the comparative discriminator D_ϕ and the generator G_θ in SAL:

$$L_D = -\mathbb{E}_{(\mathbf{x}_1, \mathbf{x}_2) \sim (\mathcal{M} \cup p_{\text{data}}(x))^2} [\log D_\phi^{Q(\mathbf{x}_1, \mathbf{x}_2)}(\mathbf{x}_1, \mathbf{x}_2)] \quad (2)$$

$$L_G = -\mathbb{E}_{(\mathbf{z}, \mathbf{x}_r) \sim (p_z(\mathbf{z}), \mathcal{M})} \left[\sum_{q \in \{>, <, \approx\}} w_q \log D_\phi^q(G_\theta(\mathbf{z}), \mathbf{x}_r) \right] \quad (3)$$

In Eq (2) and Eq (3), \mathcal{M} is the set of previous generated samples by the generator, $Q(\mathbf{x}_1, \mathbf{x}_2) \in \{>, <, \approx\}$ is the true label for the pair $(\mathbf{x}_1, \mathbf{x}_2)$, $D_\phi^q(\mathbf{x}_1, \mathbf{x}_2)$ is the probability of the comparative discriminator’s prediction being q ($q \in \{>, <, \approx\}$) for the pair $(\mathbf{x}_1, \mathbf{x}_2)$. w_q is the reward weight for the case q , which is a hyperparameter for SAL. If the generator generates a sample $G_\theta(\mathbf{z})$ that is better ($>$) than its previously generated sample \mathbf{x}_r , it receives a positive reward; if $G_\theta(\mathbf{z})$ is worse ($<$) than \mathbf{x}_r , it receives a negative reward; while if the quality of $G_\theta(\mathbf{z})$ is classified as similar (\approx) to \mathbf{x}_r , it receives zero credit. Therefore, we have $w_{(>)} > 0 = w_{(\approx)} > w_{(<)}$.

Since L_G can only be directly optimized in standard continuous GAN training, we alternatively employ the policy gradient algorithm (Sutton et al., 2000) to train the generator, as previous approaches for adversarial text generation. For SAL, we define the reward for a generated sample \mathbf{x}_g compared

with a reference sample \mathbf{x}_r which is a previous generated sample by the generator as the weighted reward based on the probability distribution of the prediction by the comparative discriminator:

$$\gamma_\phi(\mathbf{x}_g, \mathbf{x}_r) = w_{(>)} D_\phi^{(>)}(\mathbf{x}_g, \mathbf{x}_r) + w_{(<)} D_\phi^{(<)}(\mathbf{x}_g, \mathbf{x}_r) + w_{(\approx)} D_\phi^{(\approx)}(\mathbf{x}_g, \mathbf{x}_r) \quad (4)$$

In text generation, the generator G_θ obtains the reward only when one sample has been completely generated, which means no intermediate reward is gained. To relieve this problem, following the practice in SeqGAN (Yu et al., 2017), we utilize the Monte Carlo rollout method to approximate intermediate rewards by sampling unknown tokens with generated prefix $Y_{1:t}$ following generator policy G_θ till sample completion. Empirically, we found that the Monte Carlo rollout also helps to reduce the variance of the reference sample utilized for comparison. We calculate the expected reward as

$$\mathcal{R}_{\theta, \phi}(s = Y_{1:t-1}, a = y_t) = \mathbb{E}_{(\mathbf{x}_g, \mathbf{x}_r) \sim (G_\theta(Y_{1:t}), \mathcal{M})} [\gamma_\phi(\mathbf{x}_g, \mathbf{x}_r)] \quad (5)$$

The objective of the generator is to generate a sequence to maximize its expected final reward. With likelihood ratio (Sutton et al., 2000), we can formulate the gradient of the objective function for generator G_θ as:

$$\nabla_\theta J(\theta) = \sum_{t=1}^T \mathbb{E}_{Y_{1:t} \sim G_\theta} [\nabla_\theta \log(G_\theta(y_t | Y_{1:t})) \cdot \mathcal{R}_{\theta, \phi}(s = Y_{1:t-1}, a = y_t)] \quad (6)$$

To improve the training of self-adversarial learning, we borrow ideas from the field of deep reinforcement learning and propose two training techniques to improve self-adversarial training.

Scheduled rewarding Similar to the exploitation-exploration trade-off in reinforcement learning (Langford & Zhang, 2007), the positive reward assigned for actions generating better samples encourage exploration while the penalty for generating worse samples makes the generator more conservative. Intuitively, in the earlier stage of self-adversarial learning, the generator should explore better policy by receiving higher rewards for relative progress; while in the later stage, the generator should be more conservative by penalizing more for worse samples to avoid performance degradation. We simply decrease $w_{(>)}$ and increase $w_{(<)}$ linearly with training iteration and refer this technique as scheduled rewarding.

Memory replay Continuously comparing the generator with its most recent stage may suffer from the correlation between generated samples and reference samples, which makes the training process unstable. Inspired by experience replay (Lillicrap et al., 2015), we construct a memory buffer which contains samples generated in the last K training steps. Reference samples are sampled from the memory buffer rather than samples generated in the most recent stage of the generator, which empirically helps stabilize the training process.

The training process of SAL is summarized in Algorithm 1. Self-adversarial learning with the proposed comparative discriminator achieves Nash Equilibrium when the generator models the distribution of real samples perfectly. In this case, the comparative discriminator cannot successfully distinguish generated samples from real samples and tends to recognize two samples as "indistinguishable". The reward received by the generator is thus zero and training converges. However, how a non-Bernoulli GAN converges to such an equilibrium is still an open problem (Goodfellow et al., 2014; Goodfellow, 2014) and is beyond the scope of this work.

4 EXPERIMENTS

4.1 EXPERIMENTAL SETTING

Following the experimental settings in previous work (Lin et al., 2017; Guo et al., 2018; Shi et al., 2018; Zhu et al., 2018; Nie et al., 2018), we evaluate our approach in both synthetic and real datasets based on Taxygen (Zhu et al., 2018), which is a benchmark platform for evaluating adversarial text generation models. Table 1 presents the basic information of the datasets used for evaluation.

Algorithm 1 Self-Adversarial Learning With Comparative Discriminator

Require: Generator G_θ ; comparative discriminator D_ϕ ; samples of real sentences S_+ ; self-adversarial learning step g ; discriminator step k ; memory buffer \mathcal{M} for the previous generated samples

- 1: Pretrain G_θ using MLE on S_+
- 2: Generate samples with G_θ and store them into \mathcal{M}
- 3: **repeat**
- 4: **for** k steps **do**
- 5: Collect a mini-batch of balanced sample pairs (x_1, x_2) from $\mathcal{M} \cup S_+$
- 6: Update D_ϕ via Eq (2)
- 7: **end for**
- 8: **for** g steps **do**
- 9: Generate a mini-batch of samples $x_g \sim G_\theta$
- 10: Collect a mini-batch of reference samples x_r from \mathcal{M}
- 11: Update G_θ via Eq (6)
- 12: **end for**
- 13: Update \mathcal{M} with G_θ
- 14: **until** Convergence

Table 1: Description of the datasets used for evaluation

	Synthetic	Image COCO	EMNLP2017 WMT NEWS
Category	simulated data	image description	news article
Vocabulary size	5000	4682	5255
Sequence length	20/40	<37	<51
Sentence number (training)	10000	10000	270000
Sentence number (test)	10000	10000	10000

As SeqGAN (Yu et al., 2017), our generator is a single-layer LSTM (Hochreiter & Schmidhuber, 1997) and our discriminator is almost based on TextCNN (Kim, 2014) except that it concatenates the feature representation of two compared samples and outputs the probability for their comparative relations (i.e., $>$, $<$, \approx). We keep the most of the hyperparameters same with the SeqGAN except the hyperparameters introduced by our models (i.e., $w_{(>)}$, $w_{(<)}$, $w_{(\approx)}$) which are tuned based on the synthetic experiment and kept the same for the real data experiments.

We evaluate the adversarial text generation models in terms of both quality and diversity. Following the prior work, in the synthetic dataset, we use the oracle LSTM to evaluate the negative log-likelihood of our generated samples (denoted as NLL_{oracle}) as the metric to reflect quality; for the diversity metric, we use the negative log-likelihood of the synthetic dataset (denoted as NLL_{gen}) evaluated by the generator with the best quality (i.e., the best NLL_{oracle} score) during training. We also use the best $NLL_{oracle} + NLL_{gen}$ obtained during training to evaluate the quality-diversity trade-off.

For the real data experiments, we follow the previous work to apply the commonly-used BLEU scores (Papineni et al., 2002) (BLEU(F)) and the perplexity of generated samples evaluated by an open-sourced pretrained language model (Jozefowicz et al., 2016) as quality metrics since NLL_{oracle} cannot be evaluated without an oracle language model. For evaluating diversity, we employ both backward BLEU (Shi et al., 2018) (BLEU(B)) which evaluates the test data using generated samples as reference and NLL_{gen} as the metrics. To evaluate the generated samples in more aspects, we calculate frechet distance (Heusel et al., 2017) (FD) between generated samples and real data with sentence representation obtained by InferSent (Conneau et al., 2017) which is a pre-trained sentence embedding model.

We compare our approach to previous well-known adversarial text generation models including SeqGAN (Yu et al., 2017), RankGAN (Li et al., 2017) and MaliGAN (Che et al., 2017). LeakGAN (Guo et al., 2018) and RelGAN (Nie et al., 2018) focus on architecture-level modification, which is orthogonal to our work and the proposed self-adversarial learning paradigm can be applied to them as well. We provide results of the combination of LeakGAN with SAL in the Appendix.

In the following sections, we denote our proposed self-adversarial learning approach as SAL. Since adversarial training is very sensitive to random initialization and suffers from high variance, we conduct five individual runs with different random seeds for each model and report the mean and the standard deviation of the obtained results.

Table 2: Performance comparison of different models in synthetic tests where sequence length is set to 20 and 40 respectively. For all the metrics presented, the lower, the better.

Method	$NLL_{oracle}(20/40)$	$NLL_{gen}(20/40)$	$NLL_{oracle} + NLL_{gen}(20/40)$
SAL	7.71 ± 0.17 / 9.31 ± 0.03	6.58 ± 0.15 / 6.97 ± 0.05	14.29 ± 0.11 / 16.24 ± 0.03
SeqGAN	8.63 ± 0.19 / 9.63 ± 0.04	6.61 ± 0.22 / 6.98 ± 0.08	15.00 ± 0.03 / 16.35 ± 0.02
RankGAN	8.42 ± 0.31 / 9.52 ± 0.11	7.14 ± 0.34 / 7.05 ± 0.12	15.01 ± 0.02 / 16.37 ± 0.02
MaliGAN	8.74 ± 0.16 / 9.67 ± 0.03	6.62 ± 0.25 / 7.14 ± 0.09	15.03 ± 0.03 / 16.39 ± 0.03
MLE	9.05 ± 0.03 / 9.84 ± 0.02	5.96 ± 0.02 / 6.55 ± 0.02	15.02 ± 0.03 / 16.39 ± 0.01

4.2 EXPERIMENTAL RESULTS

4.2.1 RESULTS IN SYNTHETIC DATA

Table 17 shows the results in the synthetic dataset. We can observe that SAL largely outperforms the previous GANs in all metrics in both cases of sequence length 20 and 40. Although its performance in NLL_{gen} is worse than MLE as MLE directly optimizes the metric, it yields better quality-diversity trade-off than MLE training, which has not been achieved by the previous GANs, which is shown by the fact that the $NLL_{oracle} + NLL_{gen}$ for SAL is lower than that yielded by MLE, while other GANs have the same sum score with MLE, indicating that they fail to improve the quality-diversity trade-off after pretraining. This demonstrates SAL’s advantage in alleviating the mode collapse problem. We also find that the training of SAL is more stable compared with other text GANs.

In addition, we find SAL learns faster and better than the other GANs by comparing their performance curves of NLL_{oracle} during training in Figure 3, which is consistent with our intuition that the self-improvement reward mechanism in SAL can alleviate the reward sparsity issue in the earlier training stage and help the generator learn better.

Figure 3: The performance curves of NLL-oracle during training in the synthetic dataset

Figure 4: The performance curves of perplexity during training in the Image COCO dataset

4.2.2 RESULTS IN REAL DATA

The results for COCO image caption dataset are presented in Table 18 and the performance curve of the perplexity during training is shown in Figure 4. As in the synthetic data, we observe that our SAL consistently yields better results in all the metrics with stable performance (i.e., low variance) compared to the previous GANs. According to Table 18 and Figure 4, SeqGAN and our SAL can improve MLE in the quality metrics (i.e., BLEU (F) and Perplexity) while MaliGAN and RankGAN perform comparably to MLE. However, in the WMT NEWS dataset where text samples tend to be longer, we observe something different from Table 4: all the previous GANs fail to improve MLE. This is because long text generation makes the discrepancy between generated samples and real samples very large even after MLE pre-training. As a result, previous GANs fail to stably enhance the sample quality due to the reward sparsity issue. In contrast, our SAL consistently performs well and largely improves the quality metrics over MLE. In addition, we observe that the diversity of samples generated by SAL is much better than previous GANs and only marginally worse than MLE, indicating SAL is helpful in reducing the risk of mode collapse.

In addition to the automatic metrics, we also conduct human evaluation for the generated samples. As previous work (Nie et al., 2018), we randomly sample 20 sentences from each model and pool them

Table 3: Performance comparison of different models in the COCO caption generation task. Metrics from top to bottom represent respectively the generation quality, the generation diversity, and the divergence between real data of generated sentences. For all the BLEU metrics, the higher, the better; for NLL_{gen} and FD, the lower, the better.

WMT NEWS	2.35 ±0.86	2.19 ±0.88	2.24 ±0.87	2.05 ±0.91	2.65 ±0.89 ($p < 0.01$)

with anonymizing the models’ identity. We invite 20 graduate students with good English proficiency to score each sentence on a scale of 1-5 in terms of quality. According to Table 5, our SAL is consistently well rated in the human evaluation and outperforms all the baselines in both COCO and WMT NEWS datasets. We perform the Wilcoxon Rank Sum Test with the human evaluation results and find that samples generated by baseline models can be distinguished from samples generated by SAL with $p < 0.01$. Details of human evaluation procedure and samples generated by compared methods in two real-world datasets are presented in the Appendix.

4.3 DISCUSSION

To better understand SAL, we perform multiple ablation tests in both the synthetic and the real data. We employ $NLL_{oracle} + NLL_{gen}$ score with sequence length 20 as the evaluation metric for the synthetic data, denoted as NLL. For the real data, we use the perplexity of generated samples trained with COCO dataset as the evaluation metric. We compare SAL with the following reduced models:

- *CAL*: Replacing the comparison between the generated samples (i.e., self-play) to the comparison between the real and generated samples.

Table 6: Results of the ablation tests in the synthetic data and the COCO dataset.

Dataset	SAL	CAL	w/o comparative	w/o “≈”	w/o scheduled rewarding	w/o memory replay
Synthetic (NLL)	14.29 ±0.11	14.65 ±0.16	15.01 ±0.04	14.85 ±0.16	14.46±0.18	14.41 ±0.17
COCO (Perplexity)	231.3±10.8	276.7±12.5	341.8 ±13.4	291.5 ±16.3	248.3 ±14.2	254.6 ±13.7

- *w/o comparative*: Using the binary discrimination scores of other generated samples as baseline for the policy gradient algorithm, which can be considered as a combination of the self-critic training (Rennie et al., 2017) with RL-based text GANs.
- *w/o “≈”*: Replace the three-class comparative discriminator with a binary comparative discriminator by removing the “≈” class.
- *w/o scheduled rewarding* and *w/o memory replay*

The results of the ablation tests are shown in Table 6. By observing the improvement by SAL over CAL, we confirm the importance of the self-play paradigm in SAL. It is notable that the proposed comparative discriminator alone (i.e., CAL) can yield good performance, demonstrating the effectiveness of learning by comparison. When replacing the comparative discriminator with the naive combination of self-critic baseline with text GANs, the performance largely decreases because the reward sparsity issue will be intensified when subtracting two already sparse rewards, this motivates the proposed pairwise comparative discriminator which makes self-comparison possible.

In addition, we find that the “≈” option plays a critical role in improving the result, without which the performance degrades significantly because it makes the task less trivial and provides a baseline for the policy gradient algorithm. Moreover, the training techniques (i.e., scheduled rewarding and memory replay) borrowed from deep reinforcement learning are also shown useful in improving the results but not so important as the core components (e.g., self-play and the comparative discriminator).

5 RELATED WORK

Many variants of GANs (including TextGAN (Zhang et al., 2017), GSGAN (Kusner & Hernández-Lobato, 2016), SeqGAN (Yu et al., 2017), MaliGAN (Che et al., 2017), RankGAN (Lin et al., 2017), FMGAN (Chen et al., 2018), LeakGAN (Guo et al., 2018), and RelGAN (Nie et al., 2018)) have been proposed for text generation as adversarial training has received increasing attention in recent years. Typically, they address the non-differentiable issue by making continuous approximation or reinforcement learning. These approaches introduce several different architectures and optimization objectives of both the generator and the discriminator for adversarial text generation. Among the previous studies for adversarial text generation, the most related work to ours is RankGAN (Lin et al., 2017) which proposes a ranker to replace the conventional binary classifier as its discriminator for allowing the discrimination process to involve richer information. Another work whose idea is similar to ours is the relativistic discriminator (Jolicoeur-Martineau, 2018) (RGAN). It compares binary scores assigned to generated samples and real samples by subtraction as the learning signal to implicitly represent the inductive bias that half of the samples received by the discriminator is fake. In contrast, our comparative discriminator directly encodes this inductive bias and assesses generated sentences by comparison with a pairwise classifier, which provides more informative learning signals than subtraction in RGAN (Jolicoeur-Martineau, 2018) and normalized feature similarity in RankGAN (Lin et al., 2017).

6 CONCLUSION AND FUTURE WORK

We present a self-adversarial learning (SAL) paradigm for adversarial text generation. SAL rewards the generator when its comparative discriminator finds the generator becomes better than before. Through the self-improvement reward mechanism, the problem of reward sparsity and mode collapse can be alleviated and training of text GANs are more stable, which results in a better performance in the text generation benchmarks in terms of both quality, diversity, and lower variance. In the future, we plan to generalize our approach to other domains and modals to explore the potential of SAL for adversarial learning. Generated samples are presented in the Appendix together with other details, including human evaluation details and qualitative analysis of the proposed SAL.

A GENERATED SAMPLES

We present sentences generated by our proposed model and compared models to provide qualitative evaluation of different adversarial text generation models. From the presented generated samples, we can observe that samples generated by MLE training are less realistic compared with other samples. SeqGAN yield slightly better sample quality but the loss of diversity is observable even within randomly sampled 15 sentences. Adversarial training with proposed comparator, when trained by comparing with real samples, yield better quality but still lack of diversity. Finally, with the proposed self-adversarial learning paradigm, both quality and diversity of generated samples are improved.

A.1 GENERATED SAMPLES IN IMAGE COCO DATASET

Table 7: Samples generated by SAL in Image COCO dataset

a picture of a person 's umbrella in a cell phone .
 a man stands in a green field .
 a young boy riding a truck .
 a man on a motorcycle is flying on a grassy field .
 a girl on a motorcycle parked on a city street .
 a motorcycle parked in a city street .
 a group of bikers riding bikes on a city street .
 a kitchen with a cat on the hood and a street .
 a bathroom containing a toilet and a sink .
 a young woman in a kitchen with a smiley face .
 a jet plane on the side of a street .
 a dish is sitting on a sidewalk next to a baby giraffe .
 a dog on a large green bike parked outside of the motor bike .
 a person on a kawasaki bike on a race track .
 a commercial aircraft is parked in front of a kitchen .

Table 8: Samples generated by CAL in Image COCO dataset

a man is on a towel on a table outside of a real kitchen .
 a group of lambs at a tall building .
 a young boy riding a truck .
 a man on a motorcycle is flying on a grassy field .
 a man with a computer desk next to a white car .
 a cat is on the walls of a cat .
 a plane on a runway with a plane .
 an elegant , dilapidated plane are standing in front of a parking bag .
 the woman is riding a bike on their way .
 a man wearing an old bathroom with a banana .
 a plane is taking off from the ground .
 a man holding a man in front of herself .
 a woman is walking across the road .
 a kitchen with an island in green tiles .
 a clean kitchen with two small appliances .

Table 9: Samples generated by SeqGAN in Image COCO dataset

a large image of a herd of racing train .
man and woman on horse .
a plane on a runway with a plane .
a man preparing a table with wood lid .
a view , tiled floors and a man prepares food .
a man wearing an old bathroom with a banana .
a man is is with a camera .
two people are parked on a street .
a white and white black kitten eating on a table .
a toilet is lit on the walls .
a kitchen is taking off from a window .
a man is wearing glasses wearing scarf .
a kitchen with graffiti hanging off from an open plain .
two women playing with the orange .
a kitchen with an island in a clear glass .

Table 10: Samples generated by MLE in Image COCO dataset

a jet airplane flies flying through front from an airplane .
a furry tub and overhead pot .
a man in a kitchen filled with dark lights green side , ..
a cross baby field dressed making cardboard
a bathroom with a small tub and oven .
a man above a bathroom with an oven room .
a jet airliner flying through the sky .
a kitchen with a dishwasher , and plenty of pots , pans .
a person holding onto two red era arena sits on the street .
a bathroom with a toilet and a bath tub .
a cat perched on the phone and a baseball cap .
the view of the street filled with really parked at the gates on the road .
a large hairy dog on a high bike with a cake .
a man is riding a white back bench .
a narrow bed and white spotted dark tiled walls .

A.2 GENERATED SAMPLES IN EMNLP2017 WMT DATASET

Table 11: Samples generated by SAL in EMNLP2017 WMT dataset

(1) it ' s likely to be egyptian and many of the canadian refugees , but for a decade .
(2) the ministry spokesperson also said it now significant connected to the mountain.
(3) it is the time they can more competitive , where we have another \$ 99 . 100 per cent , and completely on the alternative , and that ' s being affected .
(4) we expect \$ 200 and 0 . 3 percent for all you form other , and , which then well , it ' s done .
(5) so we wouldn ' t feel very large in the game , but you fail to fund , and and the paper that ' s like its start .
(6) other countries made a playoff cut with pages by mrs . trump ' s eighth consecutive season as a president .

Table 12: Samples generated by CAL in EMNLP2017 WMT dataset

-

- (1) you know that that is great for our ability to make thinking about how you know and you ?
 - (2) when it ' s a real thing possible , is if you the first time in a time here and get .
 - (3) u . s , now government spending at the second half of four years , a country where the law will join the region to leave japan in germany .
 - (4) deputy president , the issue of government and geneva probe threats and not - backed trump , but well - changing violence for their islamic state militants were innocent people .
 - (5) he suggested in a presidential primary source and comment on its size following protests conducted by 18 , some in 2012 will be looked at tech energy hub .
 - (6) “ it ' s growing heavy hard , ” mr . romney said , he says matters that can ' t again become the asian player .
-

B CASE STUDY: WHY IT WORKS

In this section, we present several qualitative case study examples to illustrate why comparative discrimination and self-adversarial learning helps mitigate the problem of reward sparsity and mode collapse. We extract a typical sentence generated during the initial stage of adversarial learning: "a man holding a suitcase holding a phones." We see that this sentence is of limited quality and is easily recognized by binary discriminator in SeqGAN with high confidence, this makes the credit received by the generator very sparse and make training difficult. Comparative adversarial learning (CAL) where we use the comparative discriminator to assess the quality of this sample by comparing it with a real sample helps as comparative discrimination have three categories, which is less trivial. The improvement is not so much as the discrepancy of generated samples and real samples is fairly large. However, with proposed self-adversarial learning paradigm, the comparative discriminator assesses this sentence by comparing it with a previous generated sentence which is also of poor quality. The self-improvement is easier to be recognized by the comparative discriminator and make this sample get good rewards.

As the comparative discriminator has to learn a total order of sample quality which is more challenging than standard binary discrimination, the chance of the comparative discriminator to be over-trained is reduced, which make the model easier to achieve self-improvement, thus help to alleviate the reward sparsity problem.

We also extract a sentence generated in the late stages which is fairly good and fools the binary discriminator: "a woman sitting on a bench on a park." In standard adversarial text generation models, a sentence like this would keep receiving large rewards and results in mode collapse. In self-adversarial learning paradigm, this sentence is not much better than other sentences generated by the generator itself, so its reward is limited, which reduces the risk of mode collapse.

Table 15: Case study of comparative discriminator and self-adversarial learning.

Generated sentence	Reference sentence	Reward
a man holding a suitcase holding a phones.	- (SeqGAN)	0.018
a man holding a suitcase holding a phones.	a student walks in the rain with a green umbrella. (Real)	0.051
a man holding a suitcase holding a phones.	a men 's kitchen and a cow. (Self)	0.561
a woman sitting on a bench on a park.	- (SeqGAN)	0.825
a woman sitting on a bench on a park.	a young man rides his bicycle on top of a cement bench. (Real)	0.438
a woman sitting on a bench on a park.	a man sitting on a table watching a television. (Self)	0.086

C TRAINING AND EVALUATION DETAILS

C.1 MODEL DETAILS

We follow most of the hyperparameters used in the benchmark platform Tegygen Zhu et al. (2018). Specifically, the generator is a one layer LSTM with embedding size and hidden size 32. The discriminator is implemented as a TextCNN. The proposed self-adversarial learning paradigm introduce the relative weights for credit assignment when a generated sample is found to be better, indistinguishable or worse compared with another sample generated by the generator itself. We tuned it based on the performance in synthetic experiment and set $w_0 : w_2 = 1 : -0.1$.

C.2 CHOICE OF METRICS

Note that many previous works use self-BLEU Zhu et al. (2018) as a diversity metric. However, we find that there exist problem in the official implementation of the self-BLEU metric: Only in the first time of evaluation that the reference and hypothesis come from the same “test data” (i.e. the set of generated sentences). After that, the hypothesis keeps updated but the reference remains unchanged (due to “is-first=False”), which means hypothesis and reference are not from the same “test data” any more, and thus the scores obtained under this implementation are not self-BLEU scores. To this end, we modified the implementation to make sure that the hypothesis and reference are always from the same “test data” (by simply removing the variables "self.reference" and "self.is-first") and found that the self-BLEU (2-5) scores are always 1 when evaluating all the models. This problem is also discussed in the openreview of the RelGAN paper Nie et al. (2018).

Based on this consideration, we decide to employ backward-BLEU which is introduced in Shi et al. (2018) and can also evaluate the diversity of generated samples. The forward and backward BLEU resemble precision and recall of generated samples with respect to the test data, which measures the generation quality and the generation diversity respectively.

C.3 HYPERPARAMETERS

We follow most of the hyperparameters used in the benchmark platform Tegygen Zhu et al. (2018). The proposed self-adversarial learning paradigm introduce the relative weights for credit assignment when a generated sample is found to be better, indistinguishable or worse compared with another sample generated by the generator itself. We tuned it based on the performance in synthetic experiment and find $w_0 : w_2 = 1 : -0.1$ to be a good choice and fixed w_1 to be 0.

C.4 HUMAN EVALUATION

Following the human evaluation setting in RelGAN Nie et al. (2018), The text quality evaluation is based on grammatical correctness and meaningfulness (i.e. if a sentence makes sense), text formatting problems (e.g., capitalization, punctuation, spelling errors, extra spaces between words and punctuations) are ignored. Detailed criteria is provided as following:

Table 16: The human evaluation scale from 1 to 5 with corresponding criteria and example sentences.

Scale	Criterion & Example
5-Excellent	Its grammatically correct and makes sense. For example, “a man standing on a skateboard in the middle of the street .”
4-Good	It has some small grammatical errors and mostly makes sense. For example, “two women is in a cafe look outside.”
3-Fair	It has major grammatical errors but the whole still conveys some meanings. For example, “a man riding on on motor scooter and window.”
2-Poor	It has severe grammatical errors and the whole doesn’t make sense, but some parts are meaningful. For example, “a blue bike on on on a dirt bike .”
1-Unacceptable	It is basically a random collection of words. For example, “a motorcycle close close on it and .”

C.5 ADDITIONAL RESULTS ON CAL AND LEAKGAN

In this section, we present the performance comparison on SAL vs CAL (comparative adversarial learning, which uses comparative discriminator but does not train the model with self-play.) and the application of SAL on LeakGAN. We find that SAL significantly outperforms CAL on all dataset. In addition, we find that the proposed self-adversarial learning paradigm can also be applied on other text GAN architectures, e.g. LeakGAN, and help improve its performance.

Table 17: Performance comparison of different models in synthetic tests where sequence length is set to 20 and 40 respectively. For all metrics presented, lower value is better.

Method	$NLL_{oracle}(20)$	$NLL_{oracle}(40)$
SAL	7.71 \pm 0.17	9.31 \pm 0.03
CAL	8.01 \pm 0.24	9.43 \pm 0.05
LeakGAN	7.04 \pm 0.37	7.19 \pm 0.35
LeakGAN + SAL	6.69 \pm 0.29	6.91 \pm 0.27

Table 18: Performance comparison of different models in the COCO caption generation task. Metrics from top to bottom represent respectively the generation quality, the generation diversity, and the divergence between real data of generated sentences. For all BLEU metrics, higher value is better, for NLL_{gen} and FD, lower is better.

Metrics	CAL	SAL	LeakGAN	LeakGAN + SAL
BLEU-2(F)	0.767 \pm 0.03	0.785 \pm 0.02	0.749 \pm 0.03	0.798 \pm 0.03
BLEU-3(F)	0.541 \pm 0.03	0.581 \pm 0.03	0.532 \pm 0.04	0.592 \pm 0.03
BLEU-4(F)	0.337 \pm 0.03	0.362 \pm 0.02	0.353 \pm 0.03	0.369 \pm 0.02
BLEU-5(F)	0.211 \pm 0.02	0.227 \pm 0.02	0.233 \pm 0.03	0.241 \pm 0.02
Perplexity	276.7 \pm 12.5	231.3 \pm 10.8	291.4 \pm 12.5	218.2 \pm 10.8
BLEU-2(B)	0.705 \pm 0.03	0.724 \pm 0.02	0.733 \pm 0.03	0.741 \pm 0.02
BLEU-3(B)	0.479 \pm 0.03	0.503 \pm 0.03	0.512 \pm 0.03	0.529 \pm 0.03
BLEU-4(B)	0.296 \pm 0.03	0.313 \pm 0.02	0.321 \pm 0.03	0.334 \pm 0.02
BLEU-5(B)	0.191 \pm 0.03	0.198 \pm 0.02	0.206 \pm 0.03	0.211 \pm 0.02
NLL_{gen}	0.936 \pm 0.03	0.873 \pm 0.02	0.683 \pm 0.03	0.655 \pm 0.02
FD	0.058 \pm 0.016	0.051 \pm 0.014	0.048 \pm 0.016	0.044 \pm 0.014
