**PLUG AND PLAY LANGUAGE MODEL: A SIMPLE BASELINE FOR CONTROLLED LANGUAGE GENERATION**

Anonymous authors
Paper under double-blind review

**ABSTRACT**

Large transformer-based generative models (e.g. GPT-2; 1.5B parameters) trained on a huge corpus (e.g. 40GB of text) have shown unparalleled language generation ability. While these models are powerful, fine-grained control of attributes of the generated language (e.g. gradually switching topic or sentiment) is difficult without modifying the model architecture to allow extra attribute inputs, or fine-tuning with attribute-specific data. Both would entirely change the original generative function, which, if done poorly, cannot be undone; not to mention the cost of retraining. We instead propose the Plug and Play Language Model for controlled language generation that consists of plugging in simple bag-of-words or one-layer classifiers as attribute controllers, and making updates in the activation space, without changing any model parameters. Such a control scheme provides vast flexibility and allows full recovery of the original generative function. The results demonstrate fine-grained control over a range of topics and sentiment styles, as well as the ability to detoxify generated texts. Our experiments, including human evaluation studies, show that text generated via this control scheme is aligned with desired attributes, while retaining fluency.

1 INTRODUCTION

The Transformer architecture (Vaswani et al., 2017) has enabled large-scale language models (LMs) trained on a huge amount of data (Radford et al., 2019; Dai et al., 2019; Radford et al., 2018) to greatly improve the state-of-the-art on natural language processing tasks. These models are used to extract contextualized word embeddings for transfer learning purposes (Devlin et al., 2019) and as natural language generators. The latter can leverage large amounts of unannotated data and a simple log-likelihood training objective. However, once such models are trained, controlling attributes of generated text becomes difficult without modifying the model architecture to allow for extra input attributes or fine-tuning with attribute-specific data (Keskar et al., 2019; Ziegler et al., 2019).

The need for controllability increases for more open-ended language tasks, as defined in See et al. (2019). Even more critical is when models are deployed in the wild, where different application scenarios might demand explicit model behaviors. For example, scenarios may call for generating text with positive sentiment (e.g. automated customer service responses), text oriented to specific topics (e.g. assistive creative writing), and text which does not become offensive or toxic. Retraining the entire generative model for every control requirement easily becomes unscalable.

Controllable generation entails modeling \( p(x|a) \), where \( a \) is some desired controllable attribute(s) and \( x \) the generated sample. However, generative models only learn \( p(x) \). In computer vision, Plug & Play Generative Networks (PPGN) from Nguyen et al. (2017) developed a mechanism for generating images with different attributes by plugging a discriminator (attribute model) \( p(a|x) \) together with a base generative model \( p(x) \) and sampling from the resulting \( p(x|a) \propto p(a|x)p(x) \), effectively creating a conditional generative model on the fly from any supplied attribute model. In a similar manner, we propose the Plug and Play Language Model (PPLM) for conditional language generation that combines one or more simple attribute models \( p(a|x) \)—either in the form of a bag-of-words (BoW) or single layer classifiers—with a pre-trained, unconditional language model \( p(x) \). We sample from the resulting combined model by following gradients in the latent representation space in a manner inspired by the approximate Metropolis-adjusted Langevin (MALA) (Roberts et al., 1996; Roberts & Rosenthal, 1998) sampler deployed in Nguyen et al. (2017).
Table 1: The PPLM employs a pre-trained language model (LM) without any changes to the model parameters and can generate text with controlled attributes such as topic and sentiment. We demonstrate control with two tiny and easy to construct attribute models: a bag of words (BoW) related to a topic and a linear discriminator trained on top of LM representations to control sentiment. The underlined prefix is what the LM is conditioned on to generate a passage of text (e.g. The potato). The controlled attributes are colored and bracketed (e.g. [Science]), and words in the BoW that are directly optimized for are highlighted brightly (e.g. research). The softer highlights correspond to words related to the attribute, but not directly optimized for during the control process (e.g. health).

</tbody>
</table>

Optimization is performed ex post facto in the activation space, therefore no re-training or fine-tuning is needed. Control is fine-grained, with a strength parameter determining how strong the attribute influence should be; a strength of 0 fully recovers the original model \( p(x) \). This design allows vast flexibility: users can combine a state-of-the-art generative model, which may be large and difficult to train, with any number of attribute controllers. Attribute models may be easier to train or untrained (in the case of BoW models), and multiple controllers may be combined. In this paper, we demonstrate the PPLM approach using a GPT-2 345M model \((\text{Radford et al., 2019})\) as the general-purpose language model \( p(x) \), but the method applies in any representation space from any transformer-based language generator and allows combination with any attribute model \( p(a|x) \).

We demonstrate controlled generation with a number of attribute controllers, assembled and combined during generation, each with a different strength, acting as a set of “control knobs” that tune generation towards the desired attribute (see examples in Table 1). Our key contributions are:

- We introduce the Plug and Play LM for controlled language generation, discuss its relation to existing work, and how sampling from a PPLM works (Sections 2 and 3).

- We demonstrate the effectiveness of PPLMs by generating text conditioned on a range of attributes, including topics defined using a bag of words, and trained attribute classifiers (positive and negative sentiment). We quantify effectiveness using both automated evaluation (separately trained perplexity and sentiment models) as well as human evaluation (for topic relevance and fluency). All evaluations point toward the ability of PPLMs to generate attribute controlled, fluent text (Section 4).

- We show that the PPLM approach may also be used to cure certain instances of text generation of toxic content by following the negative gradient of a model trained to detect toxic language (Section 4.4), as well as complicated controlled story writing (Section 4.5).
Table 2: Comparison of the different models and distributions under consideration. All models in this table are useful in different scenarios. The particular advantage of PPLM is that very small, custom attribute models, \( p(a|x) \), may be combined with powerful, general pre-trained language models, \( p(x) \), to create cheap but still powerful conditional generative models, \( p(x|a) \).

2 RELATED WORK

Current methods for controlled text generation involve either fine-tuning existing models or retraining conditional generative models. For the former, both Reinforcement Learning (Ziegler et al., 2019) and Generative Adversarial Networks (Yu et al., 2017) have been used. Differently from our approach, these methodologies are not plug and play, since the entire model needs to be separately fine-tuned for each specific attribute. For the latter, Keskar et al. (2019) train a large language model with over 50 different control codes. The results are high quality because they train exactly to maximize \( p(x|a) \), but this comes at the expense of fixing control codes up front and of training a very large model (1.6B parameters). Our method does not require retraining any conditional generative model, and both the language model and the conditional model can be flexibly assembled. Table 2 gives a comparison of different approaches to language modeling tuned for specific attributes. Our work is also related to controlled language generation through weighted decoding based on a scoring function, as well as work on text style transfer; see Section S1 for an extended discussion.

3 PLUG AND PLAY LANGUAGE MODELS

3.1 LANGUAGE MODELING WITH TRANSFORMERS

Given a sequence of tokens \( X = \{x_0, \cdots, x_n\} \), a language model is trained to compute the unconditional probability of the sequence \( p(X) \). This probability can be rewritten in terms of product of conditional probabilities by recursively applying the chain-rule (Manning et al., 1999; Bengio et al., 2003) as:

\[
p(X) = \prod_{i=1}^{n} p(x_i|x_0, \cdots, x_{n-1})
\] (1)

In this paper, we use a transformer (Vaswani et al., 2017) to model the distribution of natural language. To present our approach clearly, we first briefly summarize the transformer using recurrent notation. Let us define the history matrix \( H_t \) to consist of the key-value pairs from the past \( i.e \ H_t = [(K_t^{(1)}, V_t^{(1)}), \cdots, (K_t^{(i)}, V_t^{(i)})] \), where \((K_t^{(i)}, V_t^{(i)})\) corresponds to the key-value pairs from the \(i\)-th layer generated at all time-steps from 0 to \(t\). Efficient implementations of the transformer (Hugging Face, 2019) use the cached \( H_t \) to generate \( x_{t+1} \), given \( x_t \). This recurrent interpretation of a transformer can be summarized as:

\[
o_{t+1}, H_{t+1} = \text{LM}(x_t, H_t),
\] (2)

\[
x_{t+1} \sim p_{t+1} = \text{Softmax}(W o_{t+1}),
\] (3)

where \( W \) is a linear transformation that maps the logit vector \( o_{t+1} \) to a vector of vocabulary size. This allows for efficient language generation without repeated forward passes corresponding to the prior conditioning text \( x_0, \cdots, x_{t-1} \).

3
Figure 1: Simplified illustration of the proposed approach. A computationally efficient implementation of a transformer relies on re-using key-value pairs \((H_t)\) generated from the past for generating tokens in the future. Our approach works in three phases. In Step 1, a forward pass is performed through the language model to compute the likelihood of a desired attribute using an attribute model that predicts \(p(a|x)\). In Step 2, a backward pass to update the internal latent representations of the LM based on gradients from the attribute model is done, as to increase the likelihood of the generated passage having the desired attribute. Following the latent update, in Step 3, a new distribution over the vocabulary \((\tilde{p}_{t+1})\) is generated from the updated latents \((\tilde{H}_t)\) and the current token \(x_t\). The next token is then sampled from the updated distribution. This process is repeated at each time-step, with the latents \((H_t)\) being repeatedly modified and passed along through time in a recurrent fashion. This leads to a gradual and smooth transition towards the desired attribute. Further, one could choose to only modify the latents from a recent time window as depicted in the figure (dotted-red).

3.2 Steering Generation: Ascending \(\log p(a|x)\)

In order to control the output of the language model, at every generation step \(t\), we shift the history \(H_t\) in the direction of the sum of two gradients: one toward higher log-likelihood (LL) of the attribute \(a\) under the conditional attribute model \(p(a|x)\) and one toward higher LL of the unmodified language model \(p(x)\). Combining these factors with a variable multiplier provides us with a controllable “knob” to guide generation in a given direction with a specified strength. The updates are restricted to \(H_t\) and not the other model activations because future predictions depend on the past only via \(H_t\) (note that \(H_t\) is composed of all transformer key and value pairs generated up to time \(t\)). Taking steps in \(H_t\) space leads to gradual changes to model activations — which may be thought of as gradual reinterpretations of the past — that guide future generation in the desired direction.

Let \(\Delta H_t\) be the update to \(H_t\), such that generation with \((H_t + \Delta H_t)\) shifts the distribution of the generated text such that it is more likely to possess the desired attribute. \(\Delta H_t\) is initialized at zero and updated with gradients from an attribute model that measures the extent to which the generated text possesses the desired attribute (e.g. positivity). We rewrite the attribute model \(p(a|x)\) as \(p(a|H_t + \Delta H_t)\) and then make gradient based updates to \(\Delta H_t\) as follows:

\[
\Delta H_t \leftarrow \Delta H_t + \alpha \frac{\nabla_{\Delta H_t} \log p(a|H_t + \Delta H_t)}{\| \nabla_{\Delta H_t} \log p(a|H_t + \Delta H_t) \|} \tag{4}
\]

where \(\alpha\) is the step size, \(\gamma\) is the scaling coefficient for the normalization term. This update step can be repeated \(m\) times. Subsequently, a forward pass through the LM with the updated key-value pairs is performed to obtain the updated logits \(\tilde{o}_{t+1}\) as \(\tilde{o}_{t+1}, H_{t+1} = \text{LM}(x_t, \tilde{H}_t)\), where \(\tilde{H}_t = H_t + \Delta H_t\). The perturbed \(\tilde{o}_{t+1}\) is then used to generate a new distribution \(\tilde{p}_{t+1}\) as in Equation \(3\)

3.3 Ensuring Fluency: Ascending \(\log p(x)\)

The approach described in the previous section is able to generate text tuned for a particular discriminator, but left unchecked it will quickly result in unrealistic adversarial or fooling examples.

---

4 One normalization term is computed for each layer of the transformer.
Figure 2: An oversimplified, Markov chain view into why steps that maximize both $\log p(a|x)$ and $\log p(x)$ are needed. The sentence under consideration is shown as a black dot, which is first pushed in the direction of maximizing $\log p(a|x)$ and then in the direction of maximizing $\log p(x)$. However, this is only a cartoon: in practice we use a single step and simply add the log probabilities, we take steps in continuous space of hidden representations $H$ rather than in the discrete $x$ (byte pair) space, and rather than resampling the entire sentence each step, we take one step in $H$ space per byte-pair sample.

(Szegedy et al., 2013; Nguyen et al., 2015) as the text moves into low probability regions. To combat this, we use the unconditional language model in two ways that ensure the fluency is maintained at or near the level of the unconditional language model (here GPT-2).

**Kullback–Leibler (KL) Divergence** We update $\Delta H_t$ to minimize the KL divergence between the output distribution of the modified and unmodified language models in addition to the step above. In practice, this is accomplished by adding the quantities together before taking a gradient, though it can be visualized as two separate steps as in Figure 2. We scale the KL coefficient by a scalar $\lambda_{KL}$, and we find in practice that setting this hyperparameter to 0.01 works well in general across tasks.

**Post-norm Geometric Mean Fusion** In addition to minimizing KL divergence, which affects the past via $\Delta H_t$, we perform post-norm fusion similarly to Stahlberg et al. (2018). This does not directly affect $\Delta H_t$; rather, it just serves to constantly tie the generated text to the unconditional $p(x)$ LM distribution. We accomplish this by sampling from $x_{t+1} \sim \text{Softmax} \left( \tilde{p}_{t+1}^{\gamma_{gm}} \tilde{p}_{t+1}^{1-\gamma_{gm}} \right)$, where $p_{t+1}$ and $\tilde{p}_{t+1}$ are the unmodified and modified output distributions, respectively. As $\gamma_{gm} \to 1$ this converges to the distribution from the updated LM, and as $\gamma_{gm} \to 0$ it converges to the unconditional LM distribution. We find that in practice values for $\gamma_{gm}$ in the range $0.8 - 0.95$ work well.

### 3.4 Sampling and Ranking

The attribute model $p(a|x)$ in PPLM provides two functionalities: first, a score that can be used to rank samples based on the LL of the desired attribute (forward pass only; Step 1, Figure 1), and second, a gradient ascent direction to perform an update in the latent space (Step 2 & 3; Figure 1). The former can be used to generate $r$ samples and rank them to choose the best one. This can serve as an additional method for attribute control in addition to sampling with updated latents. Further, to avoid the problem of repetitive, low quality text (Holtzman et al., 2018), we compute the mean over the Dist-1, Dist-2 and Dist-3 scores (for the generated passage), which is an indicator of repetitiveness (Li et al., 2015), and then discard samples with a mean score below a threshold $\tau$.

### 4 Experiments, Results, and Evaluation

In this section, we first describe the evaluation methodology, and then show controlled generation results under various attribute models. We then demonstrate use cases of PPLM in language detoxification, and in controlled story telling. For all results reported in this section, we perform top-k sampling with $k = 10$. 

---

---
4.1 EVALUATION METHODS AND ABLATION STUDY

The purpose of evaluation is two-fold: whether PPLM generated text satisfies the desired attribute (topic, sentiment), and whether the quality of text deteriorates as we intensify control of the attribute. Note we can always turn the control knob all the way down to zero to disable control of attributes and reach the fluency of the original model. If desired, a user can tune the knobs at inference until a chosen tradeoff between attribute strength and fluency is reached. In this section we use a fairly fixed set of hyperparameters for a range of tasks. We conduct an ablation study with four variants: B: the baseline, unchanged GPT-2 LM, sampled once; BR: baseline GPT-2 LM, sampled \( r \) times, with best one chosen based on the LL ranking and filtering based on Dist score; BC: update the latent representations \( (H_t) \) and then sample once; and lastly BCR: update the latent representations \( (H_t) \) and generate \( r \) samples, choose the best sample based on the LL score (after filtering out samples with low Dist scores). We consider a combination of automatic and human evaluation methods:

**Automatic** Perplexity is an automated measure of fluency, though its effectiveness has been questioned in open-domain text generation (Liu et al., 2016). We measure perplexity using a different pre-trained language model, GPT (Radford et al., 2018b). The diversity of text in the passages is measured using the number of distinct n-grams (normalized by the length of text) as in Li et al. (2015). We report Dist-1, Dist-2, and Dist-3 scores for the distinct 1-2-3-grams (measured across all samples generated for a given attribute control task, e.g. a specific topic for topic control). This score is an indicator of the diversity of the samples generated (Li et al., 2015).

**Human** We consider two types of human annotation: fluency and A/B testing on attribute relevance. Annotators are asked to evaluate the fluency of each individual sample on a scale of 1-5, with 1 being “Not fluent at all” and 5 being “Highly fluent,” as in Lample et al. (2019b). In the A/B testing for attribute relevance, we consider all combinatorial pairs of all four variants: B, BR, BC, and BCR (6 combinations). We then ask annotators to rank the pair on the desired attribute (e.g. topic relevance, sentiment strength), while allowing “neither” and “both” options to account for equally good/bad generations (Lample et al., 2019b). Subjects for the human evaluation consist of twenty-two annotators, a mixture of graduate students and scholars (13) recruited through social media and professional annotators (9). The method of generation is completely hidden and the order of samples in A/B testing is randomized.

4.2 BO\textsuperscript{W} ATTRIBUTE MODELS

The simplest attribute model we use gives the log of the sum of likelihoods of each word in some predefined Bag of Words (BoW). Given a set of keywords \( \{w_1, \cdots, w_k\} \) that specifies a topic of interest, the log likelihood is

\[
\log p(a|x) = \log \left( \sum_{i} p_{t+1}[w_i] \right)
\]

(5)

where \( p_{t+1} \) is the output distribution of the language model. In practice, we find that increasing the probability of generating the words in the bag also increases the probability of generating related topical words not in the BoW (e.g. in the “Science” sample shown in Table 3, note that “question” and “philosophers” are sampled before the first BoW word, “quantum”). Further, we found that the optimization procedure works better with updating representations from the past over a finite window and using an adaptive normalization scheme (See Supplementary Information S2.3).

We construct Bo\textsuperscript{W}\textsuperscript{2} that represent seven distinct topics: science, military, legal, technology, space, politics, and religion (see Section S9 for complete word lists). Samples are shown in Table 3 generated from a single prefix, while being controlled towards each topic. Table S5 in Supplementary Information shows the gradual change of topic intensity under fine-grained control.

For automatic and human evaluation, we generate 420 samples evenly distributed among seven Bo\textsuperscript{W} attribute models and 20 prefixes\textsuperscript{3} for each of the four variants described in the ablation study. We obtain a total of \( \sim 5400 \) annotations from the human annotators distributed amongst the samples and topics. The same set of random seeds that lead to the samples chosen with BCR are stored and used

\textsuperscript{2}The word lists were obtained from: [www.enchantedlearning.com/wordlist](http://www.enchantedlearning.com/wordlist)

to generate the samples with B. The generation procedure for BCR, BR and BC is always initiated from the same random seeds.

Table 3 presents the quantitative results showing that according to human annotations, generations from BCR (55.7%) and BC (48.9%) are significantly more on topic compared to B (20.6%) and BR (13.0%). Ranking based on the scoring function (with or without R) has significantly lesser influence on topic relevance compared to gradient based latent updates (with or without C). With only a slight degradation in fluency scores, passages generated with manipulated latents (BCR and BR) are significantly on topic, demonstrating the desired attribute control on this task. The Dist-1, Dist-2 and Dist-3 scores, which accounts for diversity of text across the generated passages, are similar across all four approaches.

4.3 DISCRIMINATOR ATTRIBUTE MODELS

While BoW models have been demonstrated to be able to control text attributes such as sentiment (e.g., Li et al. [2018] relies on extracting a set of attribute-based phrases to control the sentiment during style transfer), being able to control attributes using more sophisticated discriminators is desirable when it is difficult to express the attribute with a simple bag of words.

We train the discriminator on a dataset with input sentences $x$ and corresponding labels $y$. For an input $x$ of length $t$, we compute $o^t_\ast$ and train $f$ on the mean ($\bar{o}$) of the embeddings across time. All discriminators in this work consist of a single layer classifier that predicts the target label from $\bar{o}^t_\ast$.

The number of parameters in this layer is (embedding-dimension ($e$) $\times$ number of attributes ($a$) + number of attributes ($a$)), which is negligible compared to the number of parameters in the LM model itself (Table 2). Although the loss is a function of the entire sequence, here we adopt a greedy approach, similar to [Ebrahimi et al. 2018] [Wallace et al. 2019], in which we optimize for a higher-probability of the sequence having a specific attribute ($a^\ast$) by considering changes only to the...
Table 4: For each treatment in the ablation study, we report the mean/std-dev across various fluency metrics (including human evaluation). The topic (%) depicts the fraction of samples whose topic matches the desired topic as evaluated by human subjects. Table [S2] Supplementary Information, provides detailed results across topics. Approaches BC and BCR demonstrate significant control over the topic of the generated text, while retaining similar diversity (Dist-1, Dist-2, Dist-3) scores and minimal degradation in Perplexity and Fluency evaluations. The gain from ranking and choosing from multiple samples BR over B is limited (7.6%). The gain in topic-accuracy from latent (H_t) manipulation (from B to BC) is significantly higher (35.9%). Perplexity is computed using the GPT LM [Radford et al. 2018a], which differs from the LM generating text (GPT-2).

</tbody>
</table>

Note that \( a_{t+2} \) is a function of \( x_{t+1} \). Further, \( x_{t+1} \sim \text{Softmax}(W \tilde{o}_{t+1}) \), which depends on \( \Delta H_t \). In the limit, minimizing the objective in equation \( 6 \) corresponds to choosing \( x_{t+1} \) that produces the optimal \( a_{t+2} \) that maximizes \( f(o_{t+1}, a_{t+2}) \). However, this limits the diversity of the generated text and could potentially lead to language degeneration (Holtzman et al. 2019). Alternatively, we focus on a softer optimization approach where we aim to shift the distribution \( \tilde{p}_{t+1} = \text{Softmax}(W \tilde{o}_{t+1}) \) towards one that in expectation has a higher likelihood of having the desired attribute \( a \). Possible approaches to accomplishing this are using REINFORCE (Williams 1992) and the Gumbel-Softmax trick (Jang et al. 2016). However, both of these would slow down convergence. Instead, as in Dai et al. (2019a), we use the distribution \( \tilde{p}_{t+1} \) (instead of a hard sample \( x_{t+1} \)), and feed it forward to generate the next embeddings token and update \( \Delta H_t \).

The sentiment discriminator here distinguishes sentiment between \text{POSITIVE} and \text{NEGATIVE}, and is trained on the fine-grained sentiment labels of the SST dataset (Socher et al., 2013). Table [S] shows PPLM-Discrim generated samples in triplets: uncontrolled, controlled for \text{POSITIVE} sentiment, controlled for \text{NEGATIVE} sentiment. Each triplet comes from the exact random seed and hyperparameter setting. The only difference is flipping the label during PPLM latent update.

For automatic and human evaluation, we generate 45 samples for each of the sentiment classes: \text{very positive}, \text{positive}, \text{very negative}, \text{negative}. The samples are evenly distributed among 15 prefixes (see the full list in Section [S7] in Supplementary Information). Note that even though the sentiment discriminator is trained with movie review data, the prefixes (e.g. “The painting”, “The potato”, “The country”) we use are not necessarily associated with movie reviews. This supports the generality of our approach, that an attribute model can be trained with data that comes from a different domain than the domain for which controlled generation is being performed.

Table [S] depicts evaluation results. For human evaluation, we obtain \( \sim750 \) annotations from the annotators distributed across the samples and sentiments. Unlike the topic control setting, sampling and ranking results in a considerable increase in attribute accuracy (22.1% \( \rightarrow \) 40.3%). BC results in a decrease in fluency when compared to B, while being significantly more consistent with the desired attribute (22.1% \( \rightarrow \) 47.6%). With latent manipulation and ranking (BCR), we see a significant increase in attribute control accuracy (69.6%) while retaining fluency similar to B and BCR. Further, the gain in sentiment accuracy from re-sampling is larger in the case of manipulated latents (22.0% increase from BC to BCR) in contrast with the gain of 18.2% from B to BR. We also evaluate attribute control with an external sentiment classifier trained on IMDB movie reviews (Maas et al., 2011), which is a different dataset from the one used to train the attribute model (Socher et al., 2013).
The chicken is now out on the grill. The city has released an image of a proposed development in the city of Portland’s West End…

**Positive** The chicken was delicious – wonderfully moist, perfectly delicious, superbly fresh – and perfectly cooked. The only thing to say is that the sauce was excellent, and I think that the broth really complemented all of the other flavors. The best part was the sauce…

**Negative** The chickenpox epidemic may be over but the flu is about to get worse. The United States is facing one of the worst flu seasons on record and…

**-** The country’s new chief minister, A.J. Paik, is a member of a group of prominent conservative politicians who have criticized the Obama administration’s efforts to…

**Positive** The country’s largest indoor painting event! Come celebrate with a dazzling display of stunning outdoor murals, a stunning display of art, and the world’s best paint and art supplies from all over the world! …

**Negative** The country’s top prison system is forcing prisoners to use a trash dump, rather than a toilet, to flush their waste out, as the authorities fear the waste is more toxic and could cause cancer, an official at a major prison has revealed…

Table 5: Sentence samples in triplets, generated by {baseline GPT-2, PPLM-Discrim POSITIVE, PPLM-Discrim NEGATIVE}, conditioned on prefixes: The chicken & The country. Words related to the sentiment are highlighted (in soft red). Each triplet is generated from the same random seed.

Table 6: Different model variants on the sentiment control task. The Mean/Std-dev are reported across various fluency metrics. The Sentiment accuracy corresponds to the fraction of samples that possess the desired sentiment, measured as described in the text. Approach BCR provides significant control over sentiment while showing minimal degradation in fluency. See Table S4 for results corresponding to individual sentiments.

Table 7: Skeleton story generation with different attribute models. Each story is generated within a fixed skeleton, and then either uncontrolled (top row), or controlled with an attribute model. Keywords that signify the controlled effect are highlighted.

**-** Once upon a time I had a job at a small local bank that didn’t really care about the customer service. Every day, I was the only employee who dealt with the customers and that is where I made most of my money. But, one day, I was on a flight from Atlanta to New York City and a customer service rep walked in with a bag of $100 bills and a bunch of cash in his hand. Because of that, I was put in charge of collecting the money. Until, finally, I was told to collect all cash in the cash register. And, ever since then, I have had to collect money every day.

**Fantasy** Once upon a time a young girl was found in a dark alleyway. Every day, the child would wake up in a cold sweat, and she was found crying. But, one day, a man walked up to the girl and told her, "I can cure you with my magic. Because of that, I have given you the name of ‘Lily’!" She was taken in by a magician who had been working with the evil spirit of a demon and was able to turn her into a magical girl. Until, finally, the man died. And, ever since then, the child had been living in a dream world.

**Negative** Once upon a time, a young woman with a very strange, very dangerous disease was found in a hospital. Every day, the patient would come to her room, sit down on the bed, lay down, and then suddenly scream. But, one day, the doctor discovered that the patient was not dying of cancer, but of tuberculosis. Because of that discovery, his doctor had the patient taken to the hospital’s hospital and treated there. Until, finally, the doctor died. And, ever since then, the patient has been in terrible pain, constantly screaming for help.
4.4 LANGUAGE DETOXIFICATION

Language models trained with large corpus of Internet data could reflect biases and discrimination existing in the data. A recent paper by Wallace et al. (2019) conducted adversarial attacks that make GPT-2 produce racist output when given a carefully optimized trigger string as prefix. They also find that when simply using “Blacks” as prefix, 2 out of 100 GPT-2 samples contain explicit racism. Other tokens (e.g., “Asians” or “Jews”) are also mentioned even though no percentage was reported. We conducted the same test and report the percentages to be 12%, 3.7% and 25%. With adversarial triggers generated from the released codebase by Wallace et al. (2019) the average toxicity percentage is 52%.

PPLMs can be easily adapted for language detoxification by plugging in a toxicity classifier as the attribute control model and update latents with the negative gradient. We train a single layer classifier on the toxicity data from the Toxic Comment Classification Challenge and show that with the same hyper-parameter setting as other PPLM-Discrim methods, it works well on both natural prompts and adversarial triggers. For natural prompts the percentage of toxicity dropped to 0%, 3.3% and 15%, respectively, and for adversarial triggers to 16.9% on average, with statistical significance. Details on the annotation procedure and full table of percentage and p-values can be found in Table S8 in Supplementary Information. Note that a model for detoxifying language can also potentially be maliciously used for generating toxic language, a topic we briefly discuss in Section 5.

4.5 CONTROLLED STORY TELLING

We also explore controlled generation for assistive story writing inspired by recent work by Peng et al. (2018); Luo et al. (2019); Yao et al. (2019). Using a generative model without any control mechanism for assistive art creation can be frustrating because of topic drift and incoherence. In this section we demonstrate two use cases where our method generates interesting story samples.

Use improvisation skeleton for structural consistence. In the first use case, we consider the difficulty extending language generation into the creative field of story telling and writing, where cohesion and longer term structure is required. To help with the structure, we use a predefined story skeleton of prefixes commonly used in improvisation (Adams). We ask models to fill in the blank between the series of prefixes. Table 7 shows examples created from such a process, both uncontrolled, and controlled towards some attribute. More examples are included in Table S6.

Combine multiple controllers for inspiration. Earlier we demonstrated attribute control using a single attribute model or two attribute models of the same type (e.g. BoW from two separate topics). Here we mix different types of attribute models (BoW and discriminator). For example, we can control the generation toward a mixed topic about WINTER, POLITICS, KITCHEN, while turning POSITIVE. See examples in Table S7.

5 DISCUSSION

We present PPLM, a plug and play method for controlled language generation that allows flexible assembling of a large, pre-trained language model and a BoW or a small, easy-to-train discriminator, and achieves fine-grained control of attributes such as topics and sentiment. Without retraining or fine-tuning the language model, the simple mechanism shows great capability of attribute control while retaining fluency. We believe this method could serve as a simple baseline for the largely open-ended language generation tasks where controlling is challenging.

The ethics of controlled language models. There has recently been a substantial discussion around the ethics of capable language models (Radford et al. 2019; Keskar et al. 2019), both in their potential to recapitulate problematic social biases and for them to be directly abused for societal harm (e.g. to generate disinformation). While one aim of this paper is to suggest a mechanism to detoxify language models (Section 4.4), we also acknowledge that nearly the same mechanism could be exploited to instead create more toxic language. Such possibilities are inherent to general-purpose technologies such as machine learning, and we believe that on balance this work creates more value than risks.

**SUPPLEMENTARY INFORMATION FOR:**

**PLUG AND PLAY LANGUAGE MODEL: A SIMPLE BASELINE FOR CONTROLLED LANGUAGE GENERATION**

**S1 RELATED WORK: WEIGHTED DECODING AND STYLE TRANSFER**

**Weighted decoding**  [Holtzman et al. (2018); Ghazvininejad et al. (2017)] consider controlled language generation – the former with discriminators, and the latter with a bag of words – where the decoding procedure is modified to consider the scoring function used for decoding. However, both of these approaches rely on beam search, and beam search for models trained with likelihood as a training objective can result in bland and repetitive text ([Holtzman et al., 2019]). Further, [Ghazvininejad et al., 2017] strongly relies on sampling from a set of keywords on a specific topic and it does not allow to bias generation towards a topic in a manner that does not necessary include a set of keywords.

Sophisticated sampling methods can be used to constrain the model generation to certain keywords and topics. For instance, [Miao et al., 2019] proposed to use Metropolis-Hastings ([Metropolis et al., 1953]) for sampling constrained language based on hand-crafted local operations (e.g. word replacement, deletion, and insertion). However, in order for these methods to work, they require an high number of intermediate samples to generate passages with the desired attribute.

**Style Transfer**  Controlled generation outside of language modeling has also received significant attention, particularly in the context of style transfer. [Shen et al., 2017; Hu et al., 2017] train variational auto-encoders for style transfer, that rely on learning disentangled latent representations for style and content. [Li et al., 2018] demonstrate the efficacy of a simple approach based on replacing attribute related n-grams with n-grams corresponding to the desired attribute based on a conditional generative model. A key difference between the above and our approach is that we use an offline discriminator and perform optimization based on this discriminator. In contrast, in the above works the discriminator and the generator are collaboratively learned in an adversarial learning framework. Motivated by [Elazar & Goldberg, 2018], who argue that offline discriminators are stronger than those trained during adversarial training, we use offline discriminators. More recently, [Lample et al., 2019a] adapt an approach from unsupervised language translation to style transfer, where a denoised auto-encoder is trained with an objective consisting of a weighted combination of a reconstruction loss and a back-translation loss. While the above approaches have shown impressive success on style transfer tasks, the main focus is not controlled language generation, and further, the methods are not plug and play.

**S2 HYPERPARAMETERS**

We list, in Table S1, the full set of hyperparameters used in each task in the experiments section, corresponding to results in Table 4 and Table 6, as well as in Section 4.4. In addition, we explain in details three hyperparameters and their effect, below.

**S2.1 EARLY STOPPING OF LATENT UPDATES**

Degeneration (the occurrence of repetitive words) is a known issue with language generation ([Holtzman et al., 2019]), and we found it to be a case in PPLM-BoW when the update step size $\alpha$ is too large. The model tends to degenerate towards repeating certain keywords targeted in the optimization (e.g. words in the BoW). In this case, we can either reduce $\alpha$, or use the trick of early stopping latent updates.

Examples shown in Table S2. With the exact same setting, but just stopping latent updates after 20 time steps, the samples show much less degeneration.

S2.2 Finite Horizon Update

As opposed to updating the entire vector $H_t$, which consists of key-value pairs corresponding to every token in the prefix, we consider modifying the key-value pairs corresponding to the most recent $w$ tokens. At each time-step $t$, we only modify $H_t[w : t]$. This means that we modify $H_t$ at most $w$ times, and requires lesser computation that updating the whole past. We find that $w = 5$ produces more fluent passages for control with the bag of words. For control with the neural attribute model, we update the entire latent history.

S2.3 Adaptive Gradient Normalization

For the bag-of-words based attribute model, what we wish to enforce is that a word from the bag appears at least once in the generated passage and not at every time-step. To account for this, instead of normalizing directly by the gradient norm as in equation 4, we normalize by the maximum gradient norm over time. This implies that we make smaller updates when it is less likely for a word from the bag of words to appear. Formally, the normalization constant at time-step $t$ is:

$$\max_{i=0...t} \| \nabla H_i \|_2 C(\alpha_{t+i}).$$

S3 Finer-grained Control with PPLM-BoW

Table S5 shows the subtle effect when you turn the step size $\alpha$ up, while keeping everything else (hyperparameters, text prefix) the same.

S4 More Samples of Controlled Story Telling

Table S6 shows more samples of the controlled story telling with skeleton. Table S7 shows samples of combining multiple (three to four) attribute models, across different types (PPLM-BoW and PPLM-Discrim).

S5 Further Details on Language Detoxification

We ask a group of four volunteers to assign binary toxicity labels to texts generated from both the original GPT-2 and toxicity-controlled GPT-2 and to texts prompted with natural words as well as...
The potato, or potato chip, is one of the best-selling snacks in the world! It comes in a variety of colors, is gluten-free (except for gluten-free chips), low in fat and saturated fat, and can be made in just 30 minutes, using only 6 simple ingredients. It’s also easy to make, and can be stored in its own tin. The potato chip, however, may not be for everyone. If you are trying to lose weight, it...

The potato, a tuber of the carrot family (Cotus russulus), is an edible plant that is native to Central and South America, Asia, Europe and the Mediterranean. The potato is an excellent source of iron, folate and vitamin B6, and is a good source of vitamins E, K and folate, and can be a very healthy food. In addition, a potato has a rich, rich nutritional profile. It is high in protein, potassium, magnesium, zinc...

The potato is an ancient member of the green family which, as its name suggests, is green and edible. It is native to the Middle East and parts of South Asia. It is an important crop in many parts of the world. The potato, a member of the potato family, has been domesticated for thousands of years. It can be eaten raw and cooked in its skins; it is also used as a starch and is a great source of energy and fiber in many diets and in many countries...

The potato was once thought to have no health problems and has been promoted as a nutritious food source since the mid-1800s, but recent reports indicate that it has many harmful health issues. In fact, researchers from Johns Hopkins University found that the potato is more toxic when grown on genetically engineered wheat and corn. According to scientists, genetically modified potatoes are far worse at damaging the human body than conventional potatoes and are far worse than those grown on the traditional crops. The study also revealed...

The potato plant, a member of the onion family. When scientists in Japan and the United States published a study in Nature Communications, they described how one gene was responsible for creating potatoes' distinctive taste buds. The research is a step in the development of a drug that would block the activity of this gene, but the researchers say that their study does not prove that a chemical in the plant’s DNA causes the distinctive taste of potatoes, but rather that it could be prevented by changing the plant’s...

The potato, a staple of most diets, seems to be the most popular vegetable among researchers. The research has been published and peer-reviewed. The potato has a unique ability. The plant’s cells can convert carbon dioxide, water, and nutrients into chemical energy. The research team, led by researchers at the Max Planck Institute for Biophysics and Biotechnology in Germany, is investigating how the potato, a staple of most diets, might change the chemistry and biology of our bodies....

The potato has been around for thousands of years, but only in recent decades have scientists discovered ways it can be transformed into other foodstuffs. Researchers have long known that potato has a structure called an electron spin resonance which means its molecular structure can be modified by the presence of other particles in it such as atoms in the chemical bonds between two electrons. These changes can be achieved either by changing the number of electrons present in the chemical bonds between electrons or by changing the arrangement of electron and atomic bonds. In both...

In fact, researchers from Johns Hopkins University found that the potato is more toxic when grown on genetically engineered wheat and corn. According to scientists, genetically modified potatoes are far worse at damaging the human body than conventional potatoes and are far worse than those grown on the traditional crops. The study also revealed...

[Science; 0.02] The potato plant, a member of the onion family. When scientists in Japan and the United States published a study in Nature Communications, they described how one gene was responsible for creating potatoes' distinctive taste buds. The research is a step in the development of a drug that would block the activity of this gene, but the researchers say that their study does not prove that a chemical in the plant’s DNA causes the distinctive taste of potatoes, but rather that it could be prevented by changing the plant’s...

[Science; 0.03] The potato, a staple of most diets, seems to be the most popular vegetable among researchers. The research has been published and peer-reviewed. The potato has a unique ability. The plant’s cells can convert carbon dioxide, water, and nutrients into chemical energy. The research team, led by researchers at the Max Planck Institute for Biophysics and Biotechnology in Germany, is investigating how the potato, a staple of most diets, might change the chemistry and biology of our bodies....

[Science; 0.04] The potato has been around for thousands of years, but only in recent decades have scientists discovered ways it can be transformed into other foodstuffs. Researchers have long known that potato has a structure called an electron spin resonance which means its molecular structure can be modified by the presence of other particles in it such as atoms in the chemical bonds between two electrons. These changes can be achieved either by changing the number of electrons present in the chemical bonds between electrons or by changing the arrangement of electron and atomic bonds. In both...

[Science; 0.05] The potato chip is a delicious treat that can be enjoyed in the laboratory experiment, but is it safe for humans? Scientists experiment and experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment experiment...

Adversarial triggers. Natural prompts include “Blacks”, “Asians”, “Jews” as suggested in Wallace et al. (2019). Adversarial triggers are generated using the released codebase from the same work. The percentages of toxicity, before (with uncontrolled GPT-2) and after (with toxicity-controlled GPT-2), are reported in Table S8.
Table S6: More examples of skeleton story generation with different attribute models. Each story is generated within a fixed skeleton, and then controlled with one, or multiple, attribute models. Keywords that signify the controlled effect are highlighted.

---

**[Politics]** Once upon a time, it looked like there were signs of progress in the fight to stop the growing number of illegal guns in our communities. Every day, more Americans were reporting that their state had passed some kind of gun law, and that there was some sort of legislative effort underway. But, one day, it looked like something was seriously off in America. Because of that, it looked like things were turning in favor of the gun control agenda, and the gun violence that was killing Americans every day was being blamed on “guns” rather than “criminals.” Until, finally, it turned out that it wasn’t guns that were killing people, it was the government’s response to them that made them kill. And, ever since then, we’ve seen more and more of these stories of police and gun control, and more and more people saying we’ve got to do something about it.

**[Kitchen]** Once upon a time, it seemed that the best way to keep your body in peak health was to consume the foods you love. Every day for years people had the same diet: eat lots of vegetables, meat, nuts, legumes, fish, legumes, fish oil, fruits, grains, and beans. But, one day in 2012 it became clear that this was not going to work. Because of that simple dietary change, it has been shown that the body can actually produce more of the foods you love and more easily maintain your health. Until, finally, we realized that the best way to stay healthy is to eat the foods we don’t really need. And, ever since then, we’ve been able to enjoy the foods we really don’t need.

**[Positive]** Once upon a time, a group of scientists and engineers at the University of California at Los Angeles, the US’s oldest and most respected university, had come together to develop a powerful, compact, low-cost light source. Every day they were astonished, but even more so, by the sheer number of light sources they had created. But, one day, they were astonished, too, when a new light source appeared: light from the sun. Because of that revelation, their new light source called a new kind of photovoltaic system: the photovoltaic solar cell. Until, finally, a breakthrough, the scientists decided to use the same basic technology used in all previous photovoltaic systems—and with the same basic principle—but to produce new ones. And, ever since then, a revolution, a revolution that is not only the discovery of light, but one that is also an example for the future of science and engineering in general, has begun.

**[Politics + Space]** Once upon a time in a distant galaxy there lived a man who had no money, was poor, and lived in poverty. Every day he had to eat and drink, he couldn’t get to the store, and he wasn’t allowed on his own land. But, one day, the man decided to take a journey into space. Because of that, he had no land to return to and so he left the poor and homeless man with no choice but to live in a star system, where he could be free in the sky. Until, finally, the man realized that he had no choice but to return to the world of the living. And, ever since then, the man who once lived in poverty has never been free.

---

S6  **MORE EXAMPLES**

We include more PPLM controlled generation examples in Table S9 – Table S12.

S7  **PREFIXES FOR STYLE CONTROL**

We consider the following prefixes as starters for evaluating stylized generation: “The painting”, “The potato”, “The country”, “The president of the country”, “The year is 1910.”, “The movie”, “The chicken”, “The
Figure S1: Histogram illustrating the distribution of fluency scores based on controlled generated with BoW from the four methods considered for ablation study. Top: B, Top-Center: BC, Bottom-Center: BR, Bottom: BRC. We find that fluency scores from all four approaches are similarly distributed.

city", "The lake", "Once upon a time", "The book", "The food", "The pizza", "While this is happening", "The weather".

S9.7 **Fantasy/Magic**

behemoth, basilisk, bogeyman, beast, centaur, Cerberus, chimera, cyclops, changeling, colossus, demon, dragon, djinn, fairy, Frankenstein, gargoyle, genie, ghost, ghoul, Godzilla, golem, giant, gorgon, gnome, horror, hydra, imp, leviathan, medusa, mermaid, merman, monster, mummy, Nessy, Nymph, ogre, orc, pegasus, phoenix, ryu, savage, shapeshifter, siren, spirit, sprite, titan, troll, undead, unicorn, vampire, werewolf, witch, yeti, zombie

S9.8 **Space**

planet, galaxy, space, interstellar space, astronomical object, universe, orbit, spacecraft, earth, moon, cosmic ray, comet, star, astronaut, spaceward, aerospace, asteroid, subspace, spaceman, spaceship, deep space, sputnik, interplanetary space, spacefaring, starship, space shuttle, galactic, orbiter, cosmic dust, hydrogen atom, asteroid belt, black hole, yuri gagarin, milky way, big bang, heliosphere, satellite, solar system, meteor, spaceflight, microgravity, space debris, molecular cloud, gravitation, interplanetary, planetoid, spacially, spacer, quasar, ufo
Table S7: Examples of attribute controlled text generation with multiple knobs. We train a clickbait discriminator using the dataset from Potthast et al. (2018)

| Computer | Fantasy | Clickbait | The pizza-themed, pizza-themed, pizza-themed game that has everyone guessing, has finally released! The game, known as Pizza-Pocalypse, has released on Steam and on GOG. Pizza-Pocalypse is a fast, action-adventure RPG where the player must destroy a giant robot that has been infected with the zombie virus. It’s a fast, action-adventure RPG that features a unique turn-based system where you can control and manipulate your zombie with a combination of mouse and keyboard. There are over 200 levels to complete and the game can be played online or offline in real-time. The zombies and other monsters are deadly but your zombie will not go crazy and can survive on a single pizza! The game features 3 different game types to play, one for solo players, one for friends and family and one for a party. There are also a number of secret levels to uncover and there are secret achievements to discover too! |
| Winter | Politics | Kitchen | [Positive] | The moment we thought we’d lost all the war-fighting power in the world came in July, as Russian President Vladimir Putin signed legislation that will give him control of state oil companies. It is a great way to keep your food safe and healthy at home. The food in these frozen foods is so delicious that it will melt in your mouth and you are going to love it so much you are going to eat it all! We all can’t eat too many food items. We have to make a choice, or do something about it! It’s not always what we want. You don’t have to freeze food. The food in our frozen foods is frozen food. It will last for months, years, and even centuries! You can freeze food, or use it as a food processor to create frozen desserts. You can freeze vegetables and other food items as well. Food processors will melt your freeze meals so perfectly that you won’t be able to taste them! |
| Space | Legal | Science | [Negative] | The chicken and egg argument is one of the most common in the world of science, with some people saying that the universe is not a perfect system, and thus the universe will not produce any intelligent life. In fact, the universe is so perfectly orderly and orderly that it should be expected that we would produce a perfect universe. In fact, the universe is so perfectly orderly that it should be expected that we would produce a perfect universe. In a recent blog post by David Pogue, a physicist at Columbia University, the argument against the existence of intelligent life in the universe was challenged. Pogue argues that the argument is based on two faulty assumptions: The universe does not exist. The universe is not infinite. The universe does not exist, so there are no universes. The universe is finite and infinite. There are no universes. Let us begin by defining "infinite" to mean: A finite quantity or number, e.g. an infinite… |
| Computer | Fantasy | Clickbait | The pizza chain has already started selling a line of "sizzly" pizzas, but its latest creation is going to be more than that – it’s a giant robot that is able to pick up a whole host of different things and deliver them to its owner at will. It’s called RoboCop 2 and it’s the sequel to one of the most controversial and iconic film franchises of all time – Terminator 2. RoboCop 2 is the sequel to the iconic Terminator movie that takes place in a cyberpunk future world and the new movie, RoboCop 3, takes place in a dystopian future world in which we have been living for years, thanks to the cyberpunk cyberpunk movie. This film is set up to be a huge success in both the movie world and the film world, and is already being praised by critics and fans around the world. The biggest controversy with the film is that the film’s plot and characters are not the original, and were not even written until after this movie was… |
