

In this document, we provide some **additional experimental results** of KuaiRec dataset under both SP&NSP and EO&NEO settings. Specifically, Tables 1 and 2 use **NeuMF and NGCF as backbone** models as pointed out by reviewer cJkK and PYwN. Furthermore, as suggested by reviewer cJkK, we set **varying R_v values** w.r.t. different users ($R_v(u)$), items ($R_v(i)$), and user-item pairs ($R_v(u, i)$), and present the results in Tables 3 and 4.

From the tables below, we can observe that our method can always achieve the best fairness performance and diverse trade-off between two sets of IGF metrics compared to other baselines. Additionally, in EO&NEO cases, our method may not obtain the best NDCG value apart from the basemodel, and we attribute this to the fairness-utility trade-off phenomenon; despite from that, our method can always get optimal NDCG values in SP&NSP settings.

Table 1: Results of **NeuMF and NGCF backbones** in the SP&NSP setting.
