

325 [Re] Don't Judge an Object by Its Context: Learning to Overcome Contextual Bias

326 Appendix

327 We dedicate the appendix to providing additional details on certain sections of the main paper.

- 328 • In Section A, we describe how we obtained and processed the four datasets used in the paper.
- 329 • In Section B, we provide additional details on the biased categories identification process.
- 330 • In Section C, we describe our hyperparameter search process.
- 331 • In Section D, we discuss different model selection methods we tried while reproducing the *standard* baseline.
- 332 • In Section E, we provide more details on computational requirements.
- 333 • In Section F, we provide additional figures and tables.
- 334 • In Section G, we provide additional qualitative analyses with CAMs.
- 335 • In Section H, we provide per-category results for COCO-Stuff, DeepFashion, Animals with Attributes, and UnRel.
- 336 • In Section I, we provide the reproducibility plan we wrote at the beginning of the project.

337 A Datasets

338 In this section, we describe how we obtained and processed the four datasets used in the paper. COCO-Stuff [1] and
339 UnRel [8] are used for the object classification task, and DeepFashion [7] and Animals with Attributes [10] are used for
340 the attribute classification task. COCO-Stuff is the main dataset used for discussion of quantitative and qualitative results.
341 UnRel is used for cross-dataset experiments, i.e. testing models trained on COCO-Stuff on UnRel without fine-tuning.

342 A.1 COCO-Stuff

343 We downloaded COCO-Stuff [1] from the official homepage: <https://github.com/nightrome/cocostuff>. COCO-
344 Stuff includes all 164K images from COCO-2017 (train 118K, val 5K, test-dev 20K, test-challenge 20K), but only the
345 training and validation set annotations are publicly available. It covers 172 classes: 80 thing classes, 91 stuff classes and
346 1 class designated 'unlabeled.'

347 COCO-Stuff (COCO-2017 with "stuff" annotations added) contains the same images as COCO-2014 [6] but has different
348 train-val-test splits. The original paper follows the data split of COCO-2014 and uses 82,783 images for training and
349 40,504 images for evaluation. The image numbers are consistent between COCO-2014 and COCO-2017, so we were
350 able to map the "stuff" annotations from COCO-Stuff to the COCO-2014 images with "thing" annotations. Excluding
351 the 'unlabeled' category, we have in total 171 categories.

352 In Table A1, we report the co-occurrence, exclusive, and other counts for the paper's 20 biased category pairs. The
353 co-occurrence count is the number of images where b and c co-occur; the exclusive count is the number of images
354 where b occurs without c ; the other count is the number of remaining images where b doesn't occur.

355 During our data processing, we found a small typo in the original paper. Section 3 of the paper says "COCO-Stuff has
356 2,209 images where 'ski' co-occurs with 'person,' but only has 29 images where 'ski' occurs without 'person.'" On the
357 other hand, we found 2,180 co-occurring and 29 exclusive images in the training set. We verified with the authors that
358 our data processing was correct. Merging COCO-2014 and COCO-Stuff annotations is a nontrivial step in the pipeline.
359 We hope our published code and the Table A1 help future use.

360 A.2 DeepFashion

361 We downloaded DeepFashion [7] by following in the instructions on the official homepage: <http://mmlab.ie.cuhk.edu.hk/projects/DeepFashion.html>. The dataset consists of 5 benchmarks, out of which we use the Category
362 and Attribute Prediction Benchmark. This benchmark consists of 209,222 training images, 40,000 validation images,
363 and 40,000 test images with 1,000 attribute classes in total. Per the procedure specified by the authors, we only use the
364 250 most commonly appearing attributes. In Table A2, we report the co-occur, exclusive and other counts for the paper's
365 20 biased category pairs. It should be noted that the DeepFashion dataset was updated with additional "fine-grained
366 attribute annotations" in May 2020.
367

368 A.3 Animals with Attributes

369 Animals with Attributes (AwA) [10] is suspended and the images are no longer available because of copyright restrictions,
370 according to the official homepage: <https://cvml.ist.ac.at/AwA/>. Hence we downloaded Animals with Attributes

2 (AwA2), which is described as a "drop-in replacement" to AwA as it has the same class structure and almost the same characteristics, from the AwA2 official homepage: <https://cvml.ist.ac.at/AwA2/>. We confirmed with the authors that they used AwA2 as well. AwA2 consists of 30,337 training images with 40 animal classes and 6,985 test images with 10 other animal classes, with pre-extracted feature representations for each image. The classes are aligned with Osherson’s classical class/attribute matrix, thereby providing 85 numeric attribute values for each class. The images were collected from public sources, such as Flickr, in 2016.

In Table A3, we report the co-occurrence, exclusive, and other counts for the paper’s 20 biased category pairs. Following the description in the paper, we trained all models on the training set (40 classes) and evaluate on the test set (10 classes). For biased categories identification, following the paper description, we used the test set to determine the biased categories as these two sets contain different attribute distributions.

A.4 UnRel

We downloaded UnRel [8] from the official homepage: <https://github.com/jpeyre/unrel>. This dataset contains 1,071 images of objects out of their typical context and serves as a stress test for the models trained on COCO-Stuff. According to the paper, there are only three categories in UnRel that are shared with the 20 biased categories found in COCO-Stuff. We determined these categories to be "skateboard," "car" and "bus." Only these three categories were used in the evaluation.

B Biased categories identification

In this section, we provide additional details on the biased categories identification process discussed in Section 2.2.

For each dataset, the paper identifies the top-20 (b, c) pairs of biased categories, where b is the category suffering from contextual bias and c is the associated context category. For a given category z , let $\mathbb{I}_b \cap \mathbb{I}_z$ and $\mathbb{I}_b \setminus \mathbb{I}_z$ denote sets of images where b occurs with and without z respectively. Let $\hat{p}(I, b)$ denote the prediction probability of an image I for a category b obtained from a trained multi-class classifier. The bias between two categories b and z is defined as follows:

$$\text{bias}(b, z) = \frac{\frac{1}{|\mathbb{I}_b \cap \mathbb{I}_z|} \sum_{I \in \mathbb{I}_b \cap \mathbb{I}_z} \hat{p}(I, b)}{\frac{1}{|\mathbb{I}_b \setminus \mathbb{I}_z|} \sum_{I \in \mathbb{I}_b \setminus \mathbb{I}_z} \hat{p}(I, b)}, \quad (5)$$

which is the ratio of average prediction probabilities of b when it occurs with and without z . The category c that most biases b is determined as $c = \arg \max_z \text{bias}(b, z)$, with a condition that they co-occur frequently. Specifically, the paper

⁶We found this vague as there are two ceiling categories in COCO-Stuff: ceiling-other and ceiling-tile. We interpreted it as ceiling-other as ceiling-tile doesn’t frequently co-occur with toaster.

| Biased category pairs | | Bias | | Training (82,783) | | Test (40,504) | | Biased category pairs (Ours) | | |
|-----------------------|----------------------|--------|-------|-------------------|-----------|---------------|-----------|------------------------------|-----------------|-------|
| Biased (b) | Context (c) | Paper | Ours | Co-occur | Exclusive | Co-occur | Exclusive | Biased (b) | Context (c) | Bias |
| cup | dining table | 1.76 | 1.85 | 3,186 | 3,140 | 1,449 | 1,514 | car | road | 1.73 |
| wine glass | person | 1.80 | 1.59 | 1,151 | 583 | 548 | 304 | potted plant | furniture-other | 1.75 |
| handbag | person | 1.81 | 2.25 | 4,380 | 411 | 2,035 | 209 | spoon | bowl | 1.75 |

| clock | building | 2.39 | 1.97 | 1,410 | 1,691 | 835 | 840 | apple | fruit | 2.12 |
| sports ball | person | 2.45 | 3.61 | 2,607 | 105 | 1,269 | 55 | skis | snow | 2.22 |
| remote | person | 2.45 | 1.89 | 1,469 | 666 | 656 | 357 | handbag | person | 2.25 |
| snowboard | person | 2.86 | 2.40 | 1,146 | 22 | 522 | 11 | snowboard | person | 2.40 |
| toaster | ceiling ⁶ | 3.70 | 1.98 | 60 | 91 | 30 | 44 | skateboard | person | 3.41 |
| hair drier | towel | 4.00 | 3.49 | 54 | 74 | 28 | 41 | sports ball | person | 3.61 |
| tennis racket | person | 4.15 | 1.26 | 2,336 | 24 | 1,180 | 10 | hair drier | sink | 6.11 |
| skateboard | person | 7.36 | 3.41 | 2,473 | 38 | 1,068 | 24 | toaster | oven | 8.56 |
| baseball glove | person | 339.15 | 31.32 | 1,834 | 19 | 820 | 9 | baseball glove | person | 31.32 |

Table A1: (Left) The paper’s 20 most biased category pairs for **COCO-Stuff** and their bias values, both what’s reported in the paper and what we’ve calculated with our trained model. (Middle) The number of co-occurring and exclusive images for each pair. (Right) The 20 most biased categories we’ve identified with our trained model.

395 defines that b must co-occur at least 20% of the time with c for COCO-Stuff and AwA, and 10% for DeepFashion. In
 396 short, a given category b is most biased by c if (1) b co-occurs frequently with c and (2) the prediction probability of b
 397 drop significantly in the *absence* of c .

398 While this method can be applied to any number of biased category pairs, the paper says using $K = 20$ sufficiently
 399 captures biased categories in all datasets used the paper. We report the 20 most biased category pairs we’ve identified
 400 and compare them to those identified by the paper in Tables A1 (COCO-Stuff), A2 (DeepFashion), A3 (AwA). We
 401 discuss the results for each dataset in more detail below.

402 **COCO-Stuff:** Overall, the bias values of the paper’s biased category pairs calculated with our model are similar to
 403 the paper’s values. Furthermore, most of our biased category pairs match with the paper’s pairs. 18 of the 20 biased
 404 categories overlap, although their context categories sometimes differ.

405 **DeepFashion:** After manual cleaning per suggestion of the authors, 10 of our biased category pairs match with the
 406 paper’s. Still, the bias values of the paper’s pairs calculated with our trained model are overall similar to the paper’s
 407 values. It is worth noting that there are fewer co-occurring and exclusive images for each of the biased category pairs,
 408 compared to COCO-Stuff.

409 **Animals with Attributes:** Almost all of our biased categories match with those in the paper. We did observe in the
 410 process of determining the biased categories that for each b , there were multiple categories c which had an equally
 411 biased effect on b . That is, the bias value $\text{bias}(b, c)$ was equal over each of these c ’s. We suspect that this is because
 412 the images in AwA are labeled by animal class rather than per image, so many images share the same exact labels.
 413 Moreover, we observed that for many image examples, the baseline model’s highest prediction scores differ by less than
 414 0.001 or even 0.0001. The combination of these two events may result in extremely similar bias scores. Since there
 415 were multiple c ’s for each b , we listed the category which matched the paper’s findings whenever possible. In total, 18
 416 of our biased categories overlapped with those in the paper.

417 C Hyperparameter search

418 In this section, we describe how we conducted our hyperparameter search. The paper does not describe the hyperparameter
 419 search process, so we followed standard practice and tuned the hyperparameters on the validation set. While DeepFashion
 420 has training, validation and test sets, COCO-Stuff and AwA don’t have validation sets, so we created a random 80-20
 421 split of the original training set and used the 80 split as the training set and the 20 split as the validation set. We later
 422 confirmed with the authors that this is how they did their hyperparameter search.

| Biased category pairs | | Bias | | Training (209,222) | | Test (40,000) | | Biased category pairs (Ours) | | |
|-----------------------|-----------------|-------|------|--------------------|-----------|---------------|-----------|------------------------------|-----------------|------|

423 **Search for the *standard* model:** For COCO-Stuff, we tried varying the learning rate (0.1, 0.05, 0.01), weight decay
424 (0, 1e-5, 1e-4, 1e-3), and the epoch after which learning rate is dropped (20, 40, 60). We found that the paper’s
425 hyperparameters (0.1 learning rate dropped to 0.01 after epoch 60 with no weight decay) produced the best results. For
426 DeepFashion, we varied the learning rate (0.1, 0.05, 0.01, 0.005, 0.001, 0.0001), weight decay (0, 1e-6, 1e-5, 1e-4), and
427 the epoch after which the learning rate dropped (20, 30). We obtained the best results using a constant learning rate of
428 0.1 and weight decay of 1e-6. For AwA, we tried learning rates of 0.1 and 0.01, with various training schedules such as
429 dropping from 0.1 to 0.001, dropping from 0.01 to 0.001, and keeping a constant learning rate of 0.01 throughout. We
430 also tried varying weight decay (0, 1e-2, 1e-3, 1e-4, 1e-5), but the paper’s hyperparameters (0.1 learning rate dropped to
431 0.01 after epoch 10 with no weight decay) led to the best results. We also tried training the models longer but didn’t
432 find much improvement, so we trained for the same number of epochs as in the paper (100 for COCO-Stuff, 50 for
433 DeepFashion, 20 for AwA).

434 **Search for the "stage 2" models:** For "stage 2" models, we tried varying the learning rate (0.005, 0.01, 0.05, 0.1, 0.5)
435 and found that the paper’s learning rate of 0.01 produces the best results. We didn’t find benefits from training the
436 models longer, so following the original authors, we train all "stage 2" models (except *split-biased*) for 20 epochs on
437 top of the *standard* model and use the model at the end of training as the final model. For the *CAM-based* model, we
438 conducted an additional hyperparameter search because we got underwhelming results and degenerate CAMs with the
439 paper’s hyperparameters ($\lambda_1 = 0.1$, $\lambda_2 = 0.01$). We tried varying the regularization weight λ_2 (0.01, 0.05, 0.1, 0.5, 1.0,
440 5.0) and achieved the best results with $\lambda_2 = 0.1$.

441 D Selecting the best model epoch

442 While reproducing the *standard* model in Section 2, we tried selecting the best model epoch with four different selection
443 methods: 1) lowest loss, 2) highest exclusive mAP, 3) highest combined exclusive and co-occur mAPs, and 4) last
444 epoch (paper’s method). Note that method 4 does not require a validation set, while methods 1-3 do as they require
445 examinations of the loss and the mAPs at every epoch. Hence for datasets like COCO-Stuff and AwA that don’t have a
446 validation set, we can apply the first three methods only when we create a validation set by doing a random split of the
447 original training set (e.g. 80-20 split).

448 In Table A4, we show COCO-Stuff *standard* results with different epoch selection methods. For methods 1–3, the best
449 epoch is selected based on the loss or the mAPs on the validation set. For method 4, we simply select the last epoch.
450 Note that all numbers in the table are results on the unseen test set.

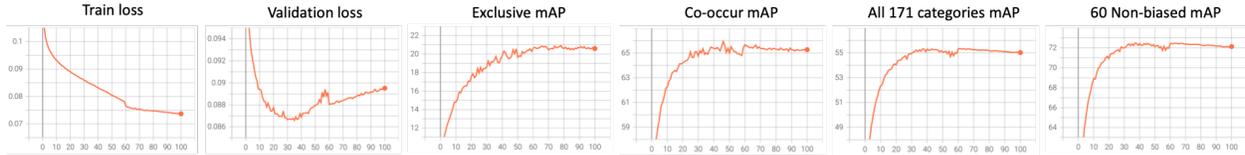

451 First considering the model trained on the 80 split, we see that selecting the epoch with the lowest (BCE) loss yields the
452 lowest mAP (row 1). The results of the other three methods (rows 2–4) are largely similar, with less than 0.4 mAP
453 difference for all fields. When we plot the progression of the losses and the mAPs (Figure A1), we see that the mAPs

454 are mostly consistent in the latter epochs. Hence, we decided that using the last epoch is a reasonable epoch selection
 455 method. With this method we also benefit from training on the full training set, which improves all four mAPs (row 5).

Table A4: COCO-Stuff *standard* baseline results with different model epoch selection methods. All numbers are results on the test set. The best results are in bold.

| Training data | Selection method | Selected epoch | Exclusive | Co-occur | All | Non-biased |
|-------------------|-------------------------------------|----------------|-------------|-------------|-------------|-------------|
| 80 split | 1) Lowest loss | 36 | 22.0 | 64.0 | 55.4 | 71.8 |
| 80 split | 2) Highest exclusive mAP | 79 | 22.9 | 64.1 | 55.2 | 71.6 |
| 80 split | 3) Highest exclusive + co-occur mAP | 68 | 23.0 | 64.2 | 55.3 | 71.8 |
| 80 split | 4) Last epoch | 100 | 22.9 | 63.8 | 55.0 | 71.4 |
| Full training set | 4) Last epoch | 100 | 23.9 | 65.0 | 55.7 | 72.3 |

Figure A1: Losses and mAPs of the COCO-Stuff *standard* model trained on the 80 split of the original training set. The validation loss and the four mAPs are calculated on the remaining 20 split which we use as the validation set.

456 E Computational requirements

457 In Table A5, we report the single-epoch training time for each method trained with a batch size of 200 using a single
 458 RTX 3090 GPU, except for *CAM-based* which is trained on two GPUs due to memory constraints. Overall, the total
 459 training time for each method range from 35-43 hours on COCO-Stuff, 22-29 hours on DeepFashion, and 7-8 hours on
 460 AWA. For inference, a single image forward pass takes 9.5ms on a single RTX 3090 GPU. Doing inference on the entire
 461 test with a batch size of 100 takes 5.6 minutes for COCO-Stuff (40,504 images), 2.7 minutes for DeepFashion (40,000
 462 images), 1.8 minutes for AWA (6,985 images), and 18.2 seconds for UnRel (1,071 images).

Table A5: Single-epoch training time (in minutes) for different methods, trained using a batch size of 200.

| Method | COCO-Stuff | DeepFashion | AWA |
|--------------------------------|------------|-------------|------|
| <i>standard</i> | 12.9 | 16.8 | 8.8 |
| <i>remove labels</i> | 12.8 | 16.8 | 8.8 |
| <i>remove images</i> | 8.4 | 16.1 | 0.5 |
| <i>split-biased</i> | 12.9 | 16.7 | 8.8 |
| <i>weighted</i> | 12.9 | 16.8 | 8.8 |
| <i>negative penalty</i> | 12.8 | 16.8 | 8.8 |
| <i>class-balancing</i> | 12.8 | 16.9 | 8.8 |
| <i>attribute decorrelation</i> | - | - | 12.8 |
| <i>CAM-based</i> | 17.3 | - | - |
| <i>feature-split</i> | 13.3 | 20.9 | 10.0 |

463 F Additional results

464 **Additional visualizations:** In Figure A2, we show visual comparison of our results and the paper’s results reported in
 465 Table 2 for the AWA and DeepFashion datasets. A similar plot for COCO-Stuff is presented in Figure 2.

466 **Cosine similarity analysis:** In Table A6, we report the cosine similarity between W_o and W_s for the *standard*,
 467 *CAM-based*, and *feature-split* methods. Consistent with the paper’s conclusion, we find that the proposed methods have
 468 weights with similar or lower cosine similarity. On the interpretation of the results, we agree that *feature-split*’s low
 469 cosine similarity between W_o and W_s suggests that the corresponding feature subspaces x_o and x_s capture different
 470 information, as intended by the method. However, we don’t understand why the cosine similarity of *CAM-based* would
 471 be lower than *standard*, as there is nothing in *CAM-based* that encourages the feature subspaces to be distinct. See
 472 Section 3.6 for additional details.

Figure A2: Performance of different methods on DeepFashion and Awa. Green lines mark our *standard* mAPs. All results can be found in Table 2.

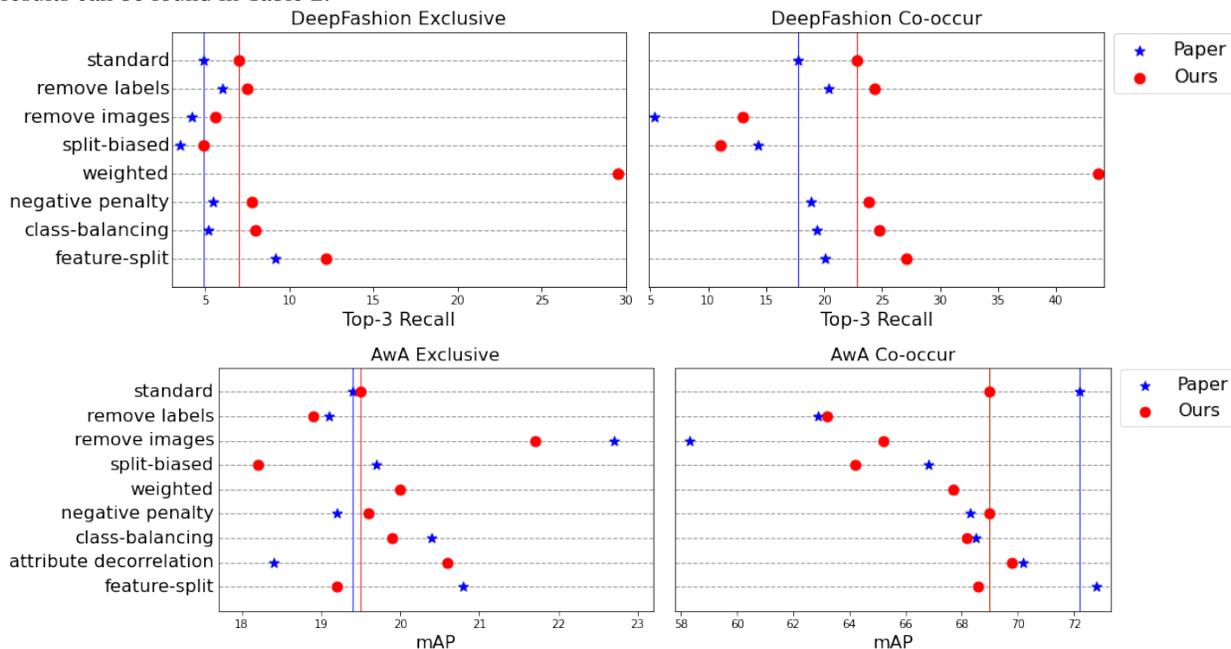

Table A6: Cosine similarity between W_o and W_s for the 20 most biased categories. We compare our reproduced results to those in paper’s Table 7. The paper does not report results for the DeepFashion and Awa datasets.

| Method | COCO-Stuff | | DeepFashion | | Awa | |
|----------------------|------------|------|-------------|------|-------|------|
| | Paper | Ours | Paper | Ours | Paper | Ours |
| <i>standard</i> | 0.21 | 0.08 | - | 0.12 | - | 0.02 |
| <i>CAM-based</i> | 0.19 | 0.07 | - | - | - | - |
| <i>feature-split</i> | 0.17 | 0.04 | - | 0.05 | - | 0.02 |

473 G Additional qualitative analyses

474 In Figures 6 through 9 of the original paper, the CAMs produced by the *CAM-based* and *feature-split* methods are
 475 compared to those of the *standard* model. Since the image IDs of the images used in these figures were not made
 476 available, we attempted to find images that closely replicated those used in the paper.

477 Figures 6 and 7 of the original paper compare the CAMs of the *CAM-based* method against those of the *standard*
 478 and *feature-split* method. The paper’s comparison between the *CAM-based* and *feature-split* models shows that the
 479 *feature-split* CAM regions cover both *b* and *c* categories, whereas the *CAM-based* model’s CAM covers mostly the area
 480 of *b*. In the majority of our examples, we found that this distinction to be less clear (see Figure A4). Likewise, the
 481 CAMs of our *CAM-based* method compared to the CAMs of our *standard* model are also only subtly different, even on
 482 instances where the *CAM-based* model succeeds but the *standard* model fails (see Figure A3).

483 Figure 8 in the original paper gives several examples images in which biased categories *b* appear away from their
 484 context *c*. Specifically, there are examples for which the *feature-split* model was able to predict *b* correctly but the
 485 *standard* model failed to do so, as well as some examples where both models failed. Our Figure A5 shows some of our
 486 own examples. Several of the examples from the original paper also came up in our own analysis. Out of all the test
 487 images, we found 1 "skateboard" examples on which our *feature-split* model was successful but our *standard* model
 488 failed, and 11 examples on which both models failed. There were 3 "microwave" examples on which only *feature-split*
 489 was successful and 131 examples on which neither model was successful. For "snowboard", there were 4 examples on
 490 which only the *feature-split* model was successful and 4 examples on which both failed.

491 Figure 9 of the original paper shows how the CAMs derived from W_o and W_s , the two halves of the *feature-split*
492 model’s feature subspace, focus on the object b and the context c , respectively. In our qualitative observations shown in
493 Figure A6, we noticed the same trend.

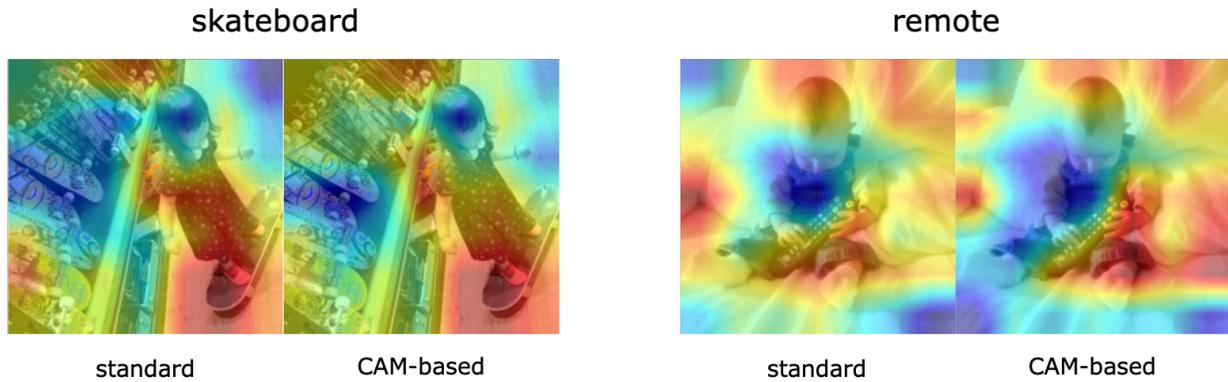

Figure A3: CAMs of examples on which our *CAM-based* model succeeds and our *standard* model fails. They are visually quite similar.

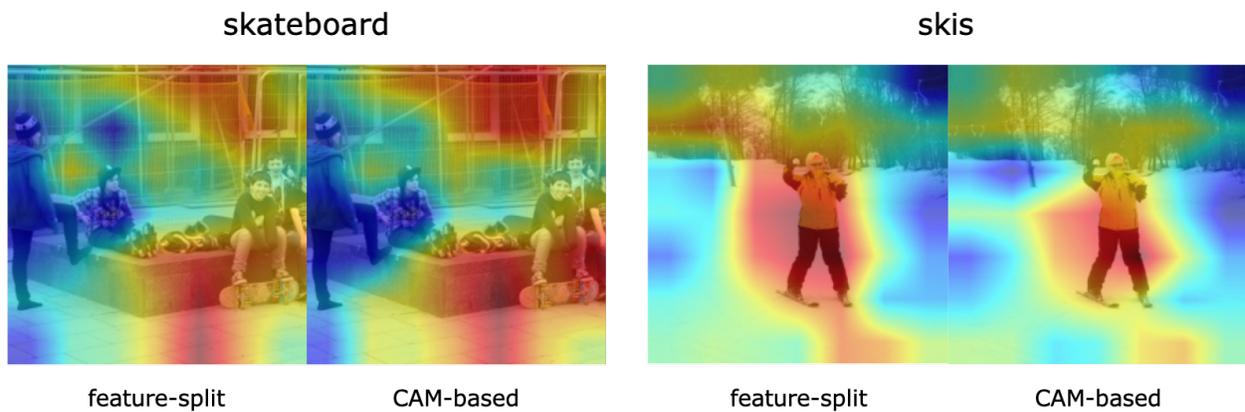

Figure A4: CAMs of examples on which our *feature-split* model succeeds and our *CAM-based* model fails. They are visually quite similar.

Figure A5: Examples on which our *feature-split* model succeeds and our *standard* model fails are outlined in green. Examples on which both models fail are outlined in red. While the original paper shows three examples of images containing *skateboard* on which the *feature-split* model succeeds but the *CAM-based* model fails, we only found one.

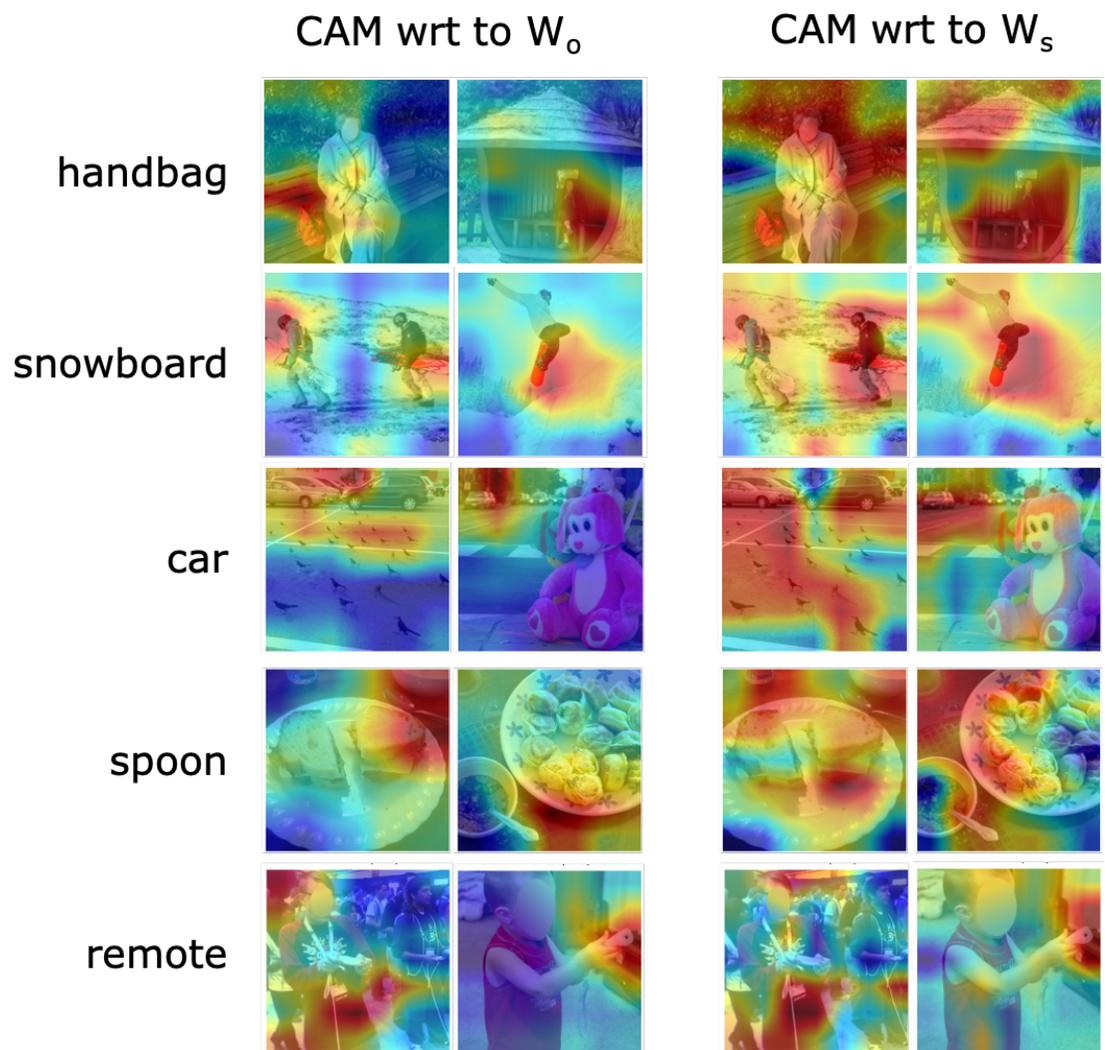

Figure A6: Interpreting the *feature-split* method by visualizing the CAMs with respect to W_o and W_s . Consistent with the paper's observations, we see that W_o focuses on the actual category (e.g. handbag, snowboard, car, spoon, remote) while W_s looks at context (e.g. person, road, bowl).

494 **H Per-category results**

495 In Table 2, we reported results aggregated over multiple categories. In this section, we present per-category results for
 496 the *standard*, *CAM-based*, and *feature-split* methods in Tables A7 (COCO-Stuff), A8 (DeepFashion), and A9 (AwA),
 497 and compare them to the paper’s results. We also present our results on the UnRel dataset in Table A10.

Table A7: Per-category results on **COCO-Stuff**. This table together with Table A1 reproduce the paper’s Table 10.

| Metric: mAP | | Exclusive | | | | | | Co-occur | | | | | |
|-----------------------|----------------------|-----------------|------|------------------|------|----------------------|------|-----------------|------|------------------|------|----------------------|------|

498 I Reproducibility plan

499 For reference, we provide the reproducibility plan we wrote at the beginning of the project. Writing this plan allowed us
500 to define concrete steps for reproducing the experiments and understand non-explicit dependencies within the paper. We
501 suggest putting together a similar plan as the order in which materials are presented in the paper can be different from
502 the order in which experiments should be run.

503 Reproducibility plan

504 The original paper points out the dangers of contextual bias and aims to accurately recognize a category in the absence
505 of its context, without compromising on performance when it co-occurs with context. The authors propose two methods
506 towards this goal: (1) a method that minimizes the overlap between the class activation maps (CAM) of the co-occurring
507 categories and (2) a method that learns feature representations that decorrelate context from category. The authors apply
508 their methods on two tasks (object and attribute classification) and four datasets (COCO-Stuff, DeepFashion, Animals
509 with Attributes, UnRel) and report significant boosts over strong baselines for the hard cases where a category occurs
510 away from its typical context.

511 As of October 20th, 2020, the authors' code is not publicly available, so we plan to re-implement the entire pipeline.
512 Specifically, we would like to reproduce the paper in the following order:

- 513 1. *Data preparation*: We will download the four datasets and do necessary processing.
- 514 2. *Biased categories identification*: The original paper finds a set of $K=20$ category pairs that suffer from
515 contextual bias. We would like to confirm that we identify the same biased categories in COCO if we follow
516 the process described in Section 3.1. and Section 7 in the Appendix.
- 517 3. *Baseline*: We will train the standard classifier (baseline) by fine-tuning a pre-trained ResNet-50 on all categories
518 of COCO. The authors describe this part as stage 1 training.
- 519 4. *CAM-based method*: We will implement the proposed method which uses CAM for weak local annotation.
520 Then using the standard classifier as the starting point, we will do stage 2 training with this method and check
521 whether it outperforms the standard classifier.
- 522 5. *Feature splitting method*: We will implement the proposed method which aims to decouple representations of a
523 category from its content. Then we will do stage 2 training with this method and check whether it outperforms
524 the standard classifier and the CAM-based method.
- 525 6. *Qualitative analysis*: Once we have trained standard, ours-CAM, and ours-feature-split classifiers, we can
526 re-create visualizations in Figures 6-9 using CAM as a visualization tool. We will compare our visualizations
527 with the figures in the paper.

528 Successfully finishing 1-6 will reproduce the main claim of the paper. Afterwards, we plan to reproduce the remaining
529 parts of the paper as time permits.

- 530 7. *Strong baselines*: In addition to the baseline standard classifier, the authors compare their two proposed
531 methods to the following strong baselines: class balancing loss, remove co-occur labels, remove co-occur
532 images, weighted loss, and negative penalty. With these additional baselines, we will be able to reproduce
533 Table 2 in full.
- 534 8. *Cross dataset experiment on UnRel*: The authors test the models trained on COCO on 3 categories of UnRel
535 that overlap with the 20 biased categories of COCO-Stuff. This experiment should be straightforward to run
536 once the UnRel dataset is ready.
- 537 9. *Attribute classification on DeepFashion and Animals with Attributes*: To reproduce attribute classification
538 experiments, we will compare performance of standard, class balancing loss, attribute decorrelation, and
539 ours-feature-split classifiers on DeepFashion and Animals with Attributes datasets.
