Abstract

Large language models (LLMs) have shown great progress in responding to user questions, allowing for a multitude of diverse applications. Yet, the quality of LLM outputs heavily depends on the prompt design, where a good prompt might enable the LLM to answer a very challenging question correctly. Therefore, recent works developed many strategies for improving the prompt, including both manual crafting and in-domain optimization. However, their efficacy in unrestricted scenarios remains questionable, as the former depends on human design for specific questions and the latter usually generalizes poorly to unseen scenarios. To address these problems, we give LLMs the freedom to design the best prompts according to themselves. Specifically, we include a hierarchy of LLMs, first constructing a prompt with precise instructions and accurate wording in a hierarchical manner, and then using this prompt to generate the final answer to the user query. We term this pipeline Hierarchical Multi-Agent Workflow, or HMAW. In contrast with prior works, HMAW imposes no human restriction and requires no training, and is completely task-agnostic while capable of adjusting to the nuances of the underlying task. Through both quantitative and qualitative experiments across multiple benchmarks, we verify that despite its simplicity, the proposed approach can create detailed and suitable prompts, further boosting the performance of current LLMs. Project page: liuyvchi.github.io/HMAW_project/

1 INTRODUCTION

Large language models (LLMs) can perform a wide range of tasks such as creating detailed literary works and generating computer codes. Yet they often give unsatisfactory responses when the prompt is poorly designed. To design better prompts that make the LLM more effective, prompt optimization has been extensively explored in recent years. Specifically, existing works on prompt optimization can be categorized as follows. The first category involves the manual design of prompts, such as the chain of thought (CoT) (Wei et al., 2022) and its variants (Kojima et al., 2022; Besta et al., 2023; Yao et al., 2023). The second category focuses on optimizing prompts on a training set that contains input-response pairs to learn a golden prompt, as demonstrated by APE (Zhou et al., 2023). The third category also uses handcrafted prompts, but different from the first category, the handcrafted prompts include examples that can guide an LLM agent to further generate prompts for a second LLM that actually provide the answer, *e.g.*, ExpertPrompting (Xu et al., 2023).

However, these methods generally have limited generalization performance across various tasks, as shown in Fig. 1 (a), (b), and (c). The first category (Wei et al., 2022) relies on *handcrafted prompts*. While they are very useful for tasks such as math, the same prompting method, if applied to other tasks, would be less effective. The second category, (Zhou et al., 2023; Yang et al., 2024a), *fine-tuned* on a specific dataset, can obtain good performance for in-domain tasks. However, these learned prompts from one domain might fail for other tasks, making them not task-agnostic. The third category (Zhou et al., 2023), which *uses LLM to adjust the prompt*, is still limited by the pre-defined examples in the handcrafted prompts. These examples only cover a finite number of scenarios and can potentially limit the quality of the modified prompt.

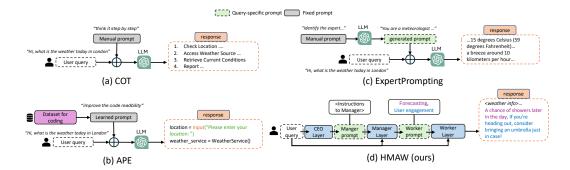

Figure 1: Examples comparing the generalization ability of existing methods and the proposed one. (a) COT (Wei et al., 2022) uses a handcrafted prompt, which might not be suitable for all tasks. (b) APE (Zhou et al., 2023) fine-tunes the prompt on a specific dataset, and its generalization capability to other scenarios is questionable. (c) ExperPrompting (Xu et al., 2023) includes few-shot examples in the system prompt to help an LLM convert the user query to a format more suitable for LLM, but these examples might not be able to cover all scenarios. (d) Our method adopts a hierarchical design in reformatting the user query. Free from pre-defined few-shot examples, the interaction between the hierarchy allows for more generalizable yet more adaptive tuning of prompts.

In this paper, we introduce a more generalizable prompt optimization method named hierarchical multi-agent workflow (HMAW). In a nutshell, our method mimics the hierarchy in companies, where the CEO and the manager create the guidelines for workers, and workers execute user-specified tasks while following these guidelines. Similarly, our method has a CEO \rightarrow Manager \rightarrow Worker workflow, which takes the initial user query as input and outputs the user response. The CEO and the Manager LLMs work in a hierarchical manner to generate accurate and detailed instructions, which are then used as prompts for the Worker LLM to generate the final answer.

Compared with existing prompt optimization methods, HMAW has two advantages that contribute to its generalization ability. First, having a hierarchy of LLM agents that each has its own job greatly simplifies the task for them. In this way, LLMs can either focus on either the overall goal (CEO), or creating a more detailed checklist (Manager), or giving specific answers (Worker). Second, our method does not require few-shot examples or any training set, thus does not fit to certain tasks, and has the additional benefit to be easy to use. As such, our method is zero-shot, task-agnostic, and prompt-specific. We compare HMAW with existing literature in Table 1.

On multiple benchmarks, we experimentally verify the effectiveness of the proposed hierarchical approach. When combined with Mixtral (Jiang et al., 2024), HMAW achieves a significant average improvement of 30.7% across 5 datasets.

2 RELATED WORK

Manual prompt engineering integrates human-like problem-solving knowledge. For example, few-shot prompting (Brown et al., 2020) allows language models (LMs) to generate responses by providing them with explicit examples. The chain-of-thought (CoT) method (Wei et al., 2022), along with its variants such as zero-shot CoT (Kojima et al., 2022), graph-of-thought (GoT) (Besta et al., 2023), and tree-of-thought (ToT) (Yao et al., 2023), intricately designs prompts to emulate various types of human-like reasoning processes. Some other works (Welleck et al., 2023; Shinn et al., 2023; Gou et al., 2024) manually craft prompts that encourage LLMs to engage in critical thinking and verification processes before delivering the final answer. Those manual prompt engineering techniques typically require carefully tailored prompts for various tasks, and for each task, the prompts used remain the same across different user queries. In comparison, we design a task-agnostic prompter that can create tailored prompts for every user query.

Automated prompt engineering methods. Instead of using fixed hand crafted in-context prompts, automated prompt engineering methods are attracting increasing attention. This line of research aims to let LLMs be prompt generators which automatically generate specific prompts for each user query so that LLMs can respond better. Recent methods include automatic prompt engineer (APE) (Zhou et al., 2023), expert prompting (EP) (Xu et al., 2023), synthetic prompting (Shao

Table 1: Method comparison based on various properties. Our method is zero-shot, task-agnostic, and query-specific, which are useful for dealing with diverse tasks.

et al., 2023), skeleton-of-thought (SoT), (Ning et al., 2024), multi-personas (Wang et al., 2023b), on-meta-prompting de Wynter et al. (2023), meta-prompting (Suzgun & Kalai, 2024), *etc.* While these methods can generate specific prompts according to different original prompts or instructions, they are generally not task-agnostic or zero-shot, where manually designed examples are required. In other words, they would not be very suitable for generalizing across ever changing landscape of LLMs. In comparison, our method is completely zero-shot, task-agnostic and prompt-specific.

Optimization based self-prompt refinement. Using optimization techniques to improve prompts is a recent focus. Early attempts including prompt tuning Lester et al. (2021) and prefix tuning Li & Liang (2021) tried to learn a trainable prefix or soft prompts for better prompting. Recent ones, *e.g.*, directional stimulus prompting (DSP) (Li et al., 2024), prompt-OIRL Sun et al. (2023), use reinforcement learning to train an auxiliary model to generate query-specific prompts. OPRO (Yang et al., 2024a) makes LLMs itself a optimizer which guides LLMs to produce outputs that align with a predefined objective. Those works typically require numerous iterations of training for each task and are thus not task-agnostic, and it is costly to adapt them to new tasks. Our work also optimizes user prompt and is thus closely related to this line of works. However, our method is learning-free and task-agnostic.

Zero-shot self-prompt refinement. Some manual prompt engineering methods, such as Zero-shot CoT (Kojima et al., 2022), Static ExpertPrompting (Xu et al., 2023), and RaR (Deng et al., 2023), follow the zero-shot paradigm. Because no prompt examples or datasets are used, these methods are typically task-agnostic as well. Despite their simplicity and ease of adaptation to various tasks, their prompt optimization capability is limited by their shallow understanding of the user query. More importantly, they are not guaranteed to be query-specific (e.g., Static ExpertPrompting and RaR), which further limits their capability. In this work, we design a hierarchical multi-agent workflow to address these shortcomings.

3 PROPOSED APPROACH

3.1 PRELIMINARIES

Notations. In language generation tasks, the language model \mathcal{M} is asked to provide responses to queries in the textual space \mathcal{T} . Given a dataset $\mathcal{D} = \{(q_i, y_i^*)\}_{i=1}^n$, where n is the number of pairs, each (q_i, y_i^*) pair consists of a text query $q_i \in \mathcal{T}$ and the corresponding golden response $y_i^* \in \mathcal{T}$. We use prompt $p \in \mathcal{T}$ to denote input of the large language model (LLM) \mathcal{M} . In practice, p may not be equal to q and can be the prompt engineering result f(q), where $f: \mathcal{T} \to \mathcal{T}, f \in \mathcal{F}$, is the prompt-engineering mapping function. In evaluation, we use a metric $s: \mathcal{T} \times \mathcal{T} \to \mathbb{R}$ to measure the quality of the responses $\hat{y}_i = \mathcal{M}(f(q_i))$. If \mathcal{D} provides golden responses, s measures the correctness of y_i , *i.e.*, $s(\hat{y}_i, y_i^*) = \mathbb{1}\{\hat{y}_i = y_i^*\}$, *e.g.*, when \mathcal{D} consists of mathematical or multiple choice questions where answers are objective. If \mathcal{D} involves open questions whose golden responses are not predetermined, we use $s(\hat{y}_i)$ to measure the quality of the response \hat{y}_i generated by \mathcal{M} .

Prompt optimization. Directly prompting LLMs \mathcal{M} using the initial human query q may not be the optimal. Ideally, an optimal prompt p* allows \mathcal{M} to generate the golden response y^* . Given a

specific pair (q_i, y_i^*) , the task of finding such p_i^* can be formulated as a prompt optimization task which aims to maximize the following expected quality score:

$$p_i^* = \operatorname*{arg\,max}_{p \in \mathcal{T}} s(y_i^*, \mathcal{M}(p \mid q_i)). \tag{1}$$

Some methods manually combine q_i with some carefully designed fixed prefix or suffix to formulate p_i^* . For example, few-shot prompting (Brown et al., 2020) uses a few examples of query-answer pairs beside the query of interest q_i ; the zero-shot chain-of-thought (CoT) (Wei et al., 2022) is formulated as ' $q_i \oplus$ [let us think step by step]'. Others use automatic methods, which are described in Section 2.

A recent line of research (*e.g.*, RAR (Deng et al., 2023), ExpertPrompting (Xu et al., 2023), Multi-Persona (Wang et al., 2023b)) focuses on leveraging the text generation capacity of LLMs to directly generate p_i^* by providing some context $C \in \mathcal{T}$ of the optimization task in Eq. 1. Those methods are deployment-friendly because of characteristics like zero-shot, task-agnostic, and query-specific. In this paper, we not only keep those characteristics but also use a workflow to optimize prompts.

3.2 HIERARCHICAL MULTI-AGENT WORKFLOW

Intuition. Now, we consider prompt optimization as a complex and challenging task where prompts are hard to optimize by traditional optimization method. Our design is motivated by recent multi-agent workflow methods (Yang et al., 2024b; Wu et al., 2024) which have shown promise in solving complex tasks. We thus employ the idea of cooperative multiple agents in the prompt optimization task.

Hierarchical workflow. We design a hierarchical workflow which performs prompt optimization and then task response generation. The user query q_i is the input of the workflow and is processed and improved by a hierarchy of agents. The workflow output the final is task response \hat{y}_i from an LLM prompted by the improved user query.

The proposed workflow operates like a company with three layers, as shown in Fig. 1 and Fig. 2. Each layer plays a different role: 'CEO', 'Manager', and 'Worker', respectively. The CEO layer takes the initial query q_i as input and outputs the CEO's instruction q_i^c to the Manager layer. The Manager layer responds to the CEO's instruction and generates its own instruction for the Worker layer. The Worker layer receives Manager instructions and is responsible for yielding the final response \hat{y}_i for the initial query q_i . The Manager and Worker layers also receive the user query q_i .

Layer design. As shown in Fig. 2, each layer has a contextual description constant c^j , a prompter f^j , and an LLM agent \mathcal{M}^j , where $j \in \{c, m, w\}$ and c, m, w refer to the CEO, manager, and worker, respectively. The context description for each layer contains the role, task description, company structure, company workflow, and important notices for this layer. The detailed context descriptions for each layer are provided in Appendix A.1.

Prompter f^j is an operator that concatenates c^j , q_i , and the instructions output from the previous layer (when j = m and j = w) into a prompt p_i^j for the LLM agent \mathcal{M}^j in this layer. For the CEO and Manager layers, the agent \mathcal{M}^j generates the result q_i^j , which serves as the instruction for the next layer. Note that the CEO layer does not receive instructions from other layers. In the worker layer, the refined prompt is p_i^* , which is fed to the Worker LLM to produce the final response \hat{y}_i .

3.3 DISCUSSION

Advantage of a hierarchical structure over a single node. For complex prompts such as improving code readability, a single node such as ExpertPrompting may not be able to exhibit a deep understanding. In the proposed hierarchical structure, global instructions are given by the CEO, and more local instructions by the manager. This allows for layered understanding of the prompt and thus makes it easy for the worker LLM to generate more satisfying answers.

Why using skip connections? As illustrated in Fig. 2, the prompters in both the manager layer and the worker layer concatenate not only the context information and the orders from the preceding layer but also the initial query q_i . This step is essential to preserve the specificity of the initial query in the system, avoiding the dilution of critical details. Moreover, if the instructions generated by a previous

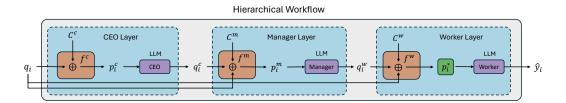

Figure 2: **Method Overview.** We propose modeling the prompt optimization problem as a zero-shot output within a multi-agent workflow. The initial query, q_i , is first inputted into the first layer of our framework (the COE layer). Before being processed by the CEO LLM agent, q_i is transformed into an LLM prompt p_i^c by the prompter f^c , which also concatenates it with the context C^c in the CEO layer. The output of the first layer, q_i^c , serves as the query from the CEO layer to the Manager layer. Similarly, the Manager Layer and the Worker Layer each include their own prompters, f^m and f^w , respectively. Besides concatenating the content of this layer, the initial query q_i is also concatenated to enhance stability. The input for the Worker LLM is our optimized prompt P_i^* , which directly triggers the LLM agent to generate the final response to the original query q_i .

layer are not correct, incorporating the initial query would reinforce the original intent, thereby preventing misinterpretation. Results in Section 5.1 demonstrate the usefulness of skip connections.

AI workflow using tools to solve complex tasks. Some existing works decompose complex task into individual steps which use different tools. After these steps are executed, it is expected that the task is complete. Our work is different in that we do not perform task decomposition and instead use the refined prompt in one go. This paper follows the standard set up of prompt optimization.

4 EXPERIMENTAL SETUP

4.1 DATASETS AND EVALUATION METRICS

ATLAS (Bsharat et al., 2023) is a manually crafted benchmark for principled prompt evaluation. It contains a standard subset featuring questions across various domains, along with a challenging subset dedicated to reasoning and other complex tasks. It contains 520 questions, and each one has the corresponding output of various LLMs such as GPT-3.5 and Llama 2.

FED (Mehri & Eskenazi, 2020) is a comprehensive collection of annotated human-system and human-human conversations, featuring 18 fine-grained dialog qualities. It is comprised of 3,348 turn-level and 1,364 dialog-level data points, totaling 4,712. FED provides evaluation at both the turn and whole dialog levels. With moderate to strong correlation to human judgment across these levels, the dataset offers a reliable benchmark for analyzing interactive dialog systems.

GSM8K. The GSM8K dataset (Grade School Math 8K) (Cobbe et al., 2021) is a collection of 8,791 grade-school-level math word problems, with detailed step-by-step solutions. It includes 7,473 training problems and 1,319 test problems. Designed by OpenAI, GSM8K serves as a benchmark for evaluating mathematical reasoning in machine learning models. We report results on its test set.

CodeNet. Project CodeNet (Puri et al., 2021) is a large-scale dataset consisting of code samples across over 50 programming languages. We follow the practice in Self-Refine (Madaan et al., 2024) and consider a random subset of 300 examples in Python. We compare different prompting optimization methods on the task of improving code readability.

Education. We collected a new datasets focusing on providing appropriate teaching responses to students. A student question can be 'we just started looking at genes and stuff in science class...what this gene editing thing is all about.'. The LLM is supposed to give a teacher-style reply which, preferably, should consider student background and is easy to understand. This dataset has 100 student questions generated by GPT4, which were then manually cleaned.

We use two **metrics** to evaluate the quality of generated responses. For the objective task GSM8K, we use the provided answer to compute the accuracy of the responses. For subjective tasks (*i.e.*, Education, ATLAS, FED, CodeNet), we follow the practice in (Madaan et al., 2024), which uses LLMs as the evaluator. Specifically, we compare the response pair generated from the optimized

Table 2: Comparison with existing prompt optimization methods. For ATLAS, FED, CodeNet, and Education datasets, we GPT-3.5 to give a preference score (%) between results obtained by 'No Prompting' and a prompt optimization method. For example, 41.4% under 'w/o' means in 41.1% of the pairs, GPT-3.5 prefers answers produced by 'No Prompt'; 63.4% under 'w' means in 63.4% of the pairs GPT-3.5 prefer answers produced after prompt optimization. Higher is better. For GSM8K, we report accuracy (%) of the generated responses *w.r.t* ground-truth answers, and higher is better. We also report average performance across the five tasks and the absolute improvement (%) of prompt optimization over no prompting.

prompt and the response generated from the initial query by asking GPT-3.5 which response it prefers. GPT3.5 then assigns a score of 1 to the preferred response and a score of 0 to the other. The prompt used for the Evaluator agent is shown in the Appendix A.2. To reduce the impact of the primacy effect issue (Wang et al., 2023a) and bias of LLMs in multiple choice questions, we follow the practice in PriDe (Zheng et al., 2024) and permute option contents. Specifically, we run each test case twice with switched response orders and compute the average score. We then average these scores across the entire test set. The average score ranges from 0 to 1.

4.2 COMPARED METHODS

We compared our method to the following types of prompt optimization methods.

Single Agent, Zero-shot. (1) No prompting. The initial query from the dataset is directly input into the LLMs without utilizing any additional prompting techniques. (2) Zero-shot CoT (Wei et al., 2022). This method adds the fixed text '*think step by step*' to the end of the initial query to formulate an optimized prompt for the LLM. (3) Rephrase and Response (RaR) (Deng et al., 2023). This method allows LLMs to rephrase and expand questions posed by humans and provides responses in a single prompt.

Single Agent, Multi-shot (1) On Meta-prompting (OMP) (de Wynter et al., 2023). It designs handcrafted meta-prompts to instruct LLMs to generate prompts for answering the initial human query. (2) Expert Prompting (EP) (Xu et al., 2023): this method uses the LLM to generate a text description of the expert identity that is suitable to solve the given query, and then attaches the generated description to the initial query to create an optimized prompt.

Multi-agent prompting. Multi-Personas (Wang et al., 2023b). This method transforms a single LLM into a cognitive synergist by engaging in multi-turn self-collaboration with multiple personas.

Feedback-based Automatic Prompt Engineer (APE) (Zhou et al., 2023). This framework automatically generate prompt candidates and selete prompts based on LLM feedback on those candidates.

5 EXPERIMENTAL RESULTS

5.1 MAIN EVALUATION

All experiments in the main evaluation are conducted using the open-source model 'Mixtral-8x7B-v0.1' (Jiang et al., 2024) as the LLM agent.

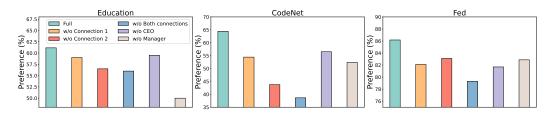

Figure 3: Ablation studies. We remove various components from the full system. Preference score (%) is reported on three datasets: Education (left), CodeNet (middle), and FED (right). These components include the two skip connections, the CEO layer and the Manager layer. It is observed that removing these components one or two at a time leads to performance drop.

HMAW achieves consistent improvements across various datasets over 'No Prompting'. On the five datasets, we compare our method with results obtained without prompting optimization. Results are summarized in Table 2. We clearly observe that HMAW improves response quality over no prompting across the five tasks. Specifically, for ATLAS, FED, CodeNet, and Education, in 64.1%, 86.2%, 70.3%, 64.4%, and 61.3% of the result pairs, respectively, GPT-3.5 prefers HMAW results over the no prompting results. For GSM8K, the accuracy of our method is 70.3%, which is +1.7% higher than the no prompting scenario. If we examine the average performance of the five tasks, result produced by HMAW is preferred by GPT-3.5 in 69.2% of all the result pairs.

HMAW is very competitive compared to the state-of-the-art prompt optimization methods. The comparative results are summarized in Table 2. We have two observations. **First**, on the ATLAS, FED, CodeNet, and Education datasets, HMAW yields the highest preference score compared with no prompting. On GSM8K, our method is slightly lower. This is partly because prompting methods like Zero-CoT are specifically designed for math problems. These methods are less generalizable to other tasks compared with our method. **Second**, if we compute the average score over the five tasks, our method has the highest score. These results indcate that our method is very competitive while operating in a zero-shot and task-agnostic manner.

Ablation studies of skip connections. As shown in Fig. 2, HMAW has two skip connections from the user query to both the Manager layer and the Worker layer. This empirical practice alleviates scenarios where HMAW loses or distorts key details from the initial user query. To investigate their impact, we conduct ablation studies by removing them from the workflow. Results on the FED, CodeNet, and Education datasets are reported in Fig. 3. We find that removing either of the skip connections leads to performance decrease on the three datasets. For example, removing the connection between user query and the Manger Layer results in preference sore decrease of 20.7% and 5.0% on the CodeNet and Education datasets, respectively. Similar decrease of 9.9% and 2.5% occurs when removing the other connection. Removing both connections results in the workflow.

Ablation studies of the CEO and Manager layers. We remove the layers one at a time from our system. If we remove the Manager layer, the CEO will directly give instructions to drive the Worker without the help of the Manager, where we have modified the context description of both CEO and Worker. If we remove the CEO layer, the Manager directly generates the instructions to Worker without CEO guidance. We compare these scenarios with full system (Fig. 2). Results on three datasets are shown in Fig. 3. We clearly find that removing either layer results in worse preference scores. For example, removing the Manager layer leads the preference score to drop by 11.5%, 3.3%, and 12.1% on the three datasets, respectively.

5.2 FURTHER ANALYSIS

Effectiveness of HMAW is consistent across different LLMs. Here we use GPT-3.5 and GPT-4 as the LLM agents in our designed workflow in replace of Mixtral. But we still use GPT-3.5 for evaluation. Experimental results are shown in Table 3, where we have similar observations to Table 2. First, for the three tasks, HMAW is consistently better than no prompting under both GPT-3.5 and GPT-40 agents, evidenced by preferences scores being consistently greater than 50%. **Second**, in most scenarios our method is superior to Dynamic-EP and APE. These results again indicate the effectiveness of our method.

			GP	ГЗ.5					GP	Т4о		
Method	FI	ED	Cod	eNet	Educ	ation	FI	ED	Cod	eNet	Educ	ation
	w/o	W	w/o	w	w/o	w	w/o	w	w/o	w	w/o	W
Dynamic-EP	25.6	74.4	20.9	79.1	48.0	52.0	22.2	77.8	24.9	75.1	44.5	55.5
APE	46.0	54.1	43.2	56.8	49.5	51.5	36.2	63.8	15.8	84.3	41.8	58.2
HMAW (Ours)	8.6	91.4	4.6	95.3	27.0	73.0	21.1	78.9	21.6	78.4	38.5	61.5

Table 3: Impact of different LLMs on our method. We replace the default Mixtral-8x7B-v0.1 with GPT-3.5 and GPT-4 as the base LLMs to optimize prompts and generate responses. Three subjective datasets are used. We use the same preference score as Table 2.

Impact of having more layers in the workflow. It is interesting to investigate how the number of workflow layers influences the performance of our method. To this end, we create as many as six roles. Fig. 4 presents the preference scores for responses generated using HMAW with 1 to 6 layers on the Education dataset, with GPT-3.5 as the LLM agent. Note that when increasing the number of layers, we always keep Worker as the last layer to generate final responses. The details of company structure for different setup on total layer number are described in Appendix B. Our results the Worker-Manager-CEO workflow has the best performance. Beyond three layers, the performance does not improve and instead worsens. It suggests that there is an optimal number of layers which balances system complexity and effectiveness. Therefore, we empirically choose 3 layers as the default setting.

Effectiveness of other workflow contexts. The default context of our workflow is based on a company structure. To investigate the impact of the context on

the effectiveness of prompt optimization, we test three other scenarios: Government, University and Temple on the Education dataset, where the hierarchies are introduced in Appendix B. Results are shown in Table 4, where the company structure is most competitive. An interesting finding is that the University structure is not the best, because the Education dataset primarily contains middle/high-school questions. In summary, the company structure generalizes very well, while certain structure contexts tend to benefit certain tasks.

Impact of disordered company structure. We now use a reverse structure where Worker gives high-level instructions, Manager gives detailed instructions, and CEO executes the refined user query. Compared with the original one, the preference score on the Education dataset drops from 73.0% to 58.5%. It indicates that the reporting line contains useful semantic meanings and should not be changed.

Computational cost. Our Experiments are conducted on both local LLMs and the remote API request. Experiments conducted on the Mixtral LLM are implemented in local by using 8× Nvidia GTX

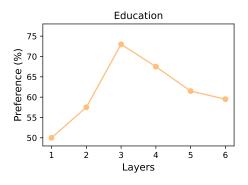

Figure 4: Impact of the number of workflow layers. The preference scores for responses generated using HMAW with different numbers of layers (1-6) are reported on the Education dataset. GPT-3.5 is used as the LLM agent. Three layers (CEO-Manager-Worker) yields the highest preference score.

Table 4: Comparison between various workflow contexts. The increase in preference scores is reported on the Education Dataset. GPT-3.5 is used as the LLM agent. We observe that all contexts bring improvement, and our default setting (company) is the best.

Context	Ours	Gov.	Uni.	Temple
Preference (%)	73.0	69.0	59.0	52.0

3090 GPUs. On the five datasets, *i.e.*, ATLAS, FED, GSM8K, CodeNet, and Education, the average zero-shot inference time cost per sample without prompt optimization is approximately 4.36, 0.70, 1.40, 2.27, and 3.74 seconds, respectively. When the proposed prompt optimization method is used, the average additional time cost per sample is approximately 9.97, 5.14, 4.30, 7.27, and 7.76 seconds, respectively. This corresponds to a 228.57%, 734.29%, 306.57%, 320.88%, and 207.49% increase,

User Query

I got this homework thing where I need to look at these DNA letters and find parts that might be, like, super important because they've been around for a long time and haven't changed much, I guess? But it's kinda confusing, and i'm not really sure what I'm supposed to be looking for. We just started learning about genes and stuff, and it's all new to me CEO to Manger nager, the user is seeking guidance on a genetics homework task that involves analyzing DNA sequences for conserved regions, which are sections that have remained largely changed over time. They are new to the topic of genes and could benefit from a simplified explanation and a step-by-step approach to identifying these conserved regions. Please provide a detailed yet understandable prompt for the Worker LLM to generate a tailored, engaging, and accurate response for the user. Emphasize the importance of conserved region ear process for their Manger to Worker Worker LLM, the user is a beginner in genetics and needs help understanding how to identify conserved regions in DNA sequences for their homework. Conserved regions are sections of DNA that have remained largely unchanged over time and are crucial to understanding the importance of specific genes. To create a tailored, engaging, and accurate response for th r, consider the following st in your e 1. Begin with a brief introduction to ... 2. Define conserved regions and explain why they are significant... 3. Outline a simple, step-by-step process for identifying conserved regions given DNA sequence, including: a. Explaining the concept of ... b. Highlighting the importance of comparing DNA sequences from various species to identify conserved regions. c. Demonstrating how to use tools and resources... to alignment and analyze the results. d. Providing examples ... 4. Encourage the user to ask ... ensuring they feel supported.... By following these guidelines, you will help the user grasp the concept of conserved regions in DNA and provide them with the necessary tools to complete their homework confidently. Worker Response Hellol I'd be happy to help you with your genetics homework. Let's start with the basics: DNA, or deoxyribonucleic acid, is the molecule ... Genes are segments of DNA that contain the instructions for making proteins, which are the complex molecules that play many critical rol plecules that play many critical roles in the body. Now, let's talk about conserved regions. These are sections of DNA that have remained largely unchanged over time, even between different species. This is because they are crucial tifying conserved regions in DNA sequences is important for understanding the importance of specific genes and how they have evolved over tim Here's a simple step-by-step process for identifying conserved regions in a given DNA seg **Multiple Sequence Alignment*: This is a process that aligns the DNA sequences of different species to identify regions of similarity. It's like lining up several sentences to find ...
 **Comparing DNA Sequences*: By comparing DNA sequences from various species, you can identify conserved regions. These are regions where the DNA sequence is similar ...
 Using Tools and Resources: There are many online databases and software tools that can help you perform multiple sequence alignment and analyze the results. For example ...
 Examples of Conserved Regions: To help you understand the practical applications of your homework, here are a few examples of genes that have conserved regions: The gene for hemoglobin, the protein in red blood cells that carries oxygen, has conserved regions across different species. The gene for the enzyme cytochrome c, which is involved in cellular respiration, also has conserved regions. I hope this helps! Remember, learning about genetics can be complex, but don't hesitate to ask questions and seek additional resources if needed. Good luck with your homework!

Figure 5: An example of prompt optimization using HMAW on the Education dataset. A student poses a question about genetics. CEO creates an instruction to Manager, who then generates instructions to Worker. Based on this, Worker delivers the final response. Colored texts indicate content coherence: green highlights the user background, purple focuses on the topic of the task, orange indicates the proposed solution, red highlights solution details, and blue emphasizes the tone of the response. These layers and cross-layer correspondences demonstrate how HMAW effectively optimizes the prompt and responds to specific user needs. Each step adds specificity and applicability, allowing for accurate and intuitive LLM responses.

respectively. In comparison, the time increase percentage per sample for Dynamic-EP is 535.16%, 294.98%, 448%, 306.57%, and 320.88%, respectively. The higher inference cost of our method can be well offset by the improvement of task performance. In future we will study workflow pruning methods to reduce the number of tokens while maintaining accuracy.

A case study. We conduct qualitative analysis of the the prompts generated in our workflow and how it helps the final response generation procedure. In Fig. 5, we illustrate the hierarchical process of generating responses using HMAW. The process begins with the CEO layer, which sets high-level guidelines tailored to the user's background and specific inquiry. The Manager layer then interprets these guidelines, adding detail and context to direct the response formulation. Finally, the Worker layer produces the final response, ensuring it is coherent, professional, and empathetic, taking into full account the user's limited familiarity with the topic. This structured approach ensures that the response effectively addresses the user's query and matches their level of understanding.

6 CONCLUSION

This work introduces a new prompt optimization method based on a hierarchical company structure, where CEO, Manager, and Worker have different job contexts but overall serve the same purpose of effectively refining the user prompt. Based on the user query and the layer context, the CEO layer generates a high-level instruction to the Manager layer. In a similar manner, the Manager further generates a more detailed instruction the Worker. Worker gives a refined prompt by concatenating the Manager instruction, user query, and its layer context, which is used for response generating. This structure is zero-shot, prompt-specific, and task-agnostic. On five different tasks including education, conversation, math, question answering, and coding, the generalization performance of our method compares favourably with existing methods. Our future work is to automate the workflow design to more efficiently handle different user queries.

A CONTEXT DESCRIPTIONS

A.1 CONTEXT DESCRIPTIONS FOR HMAW

In Fig. 2, each layer has its own context description. In this section, we show the description details for the CEO, Manager and Worker Layer in Table 6, Table 7 and Table 8, respectively.

A.2 CONTEXT DESCRIPTIONS FOR EVALUATOR

As described in Section 4, we use GPT3.5 as the evaluator to provide preference scores for a pair of responses. The context (prompt) used to this evaluator is shown in Fig. 9

B WORKFLOW STRUCTURES

Changing the Number of Layers. In our experiments, we investigate the impact of the number of layers in our workflow. The structures for each setting are shown as follows.

- 1 Layer: the same as without prompting.
- 2 Layers: $CEO \rightarrow Worker$.
- 3 Layers: CEO \rightarrow Manager \rightarrow Worker.
- 4 Layers: CEO \rightarrow Senior Manager \rightarrow Manager \rightarrow Worker.
- 5 Layers: CEO \rightarrow Senior Manager \rightarrow Manager \rightarrow Supervisor \rightarrow Worker.
- 6 Layers: CEO \rightarrow Senior Vice President \rightarrow Vice President \rightarrow Director \rightarrow Manager \rightarrow Worker.

	Manger Context	
<pre>**Your ROLE**: <manager> **Description**: You are the MANAGER in an entirely is to generate the best possible response tailored</manager></pre>		
Company Structure: CEO (LLM) -> MANAGER (LLM) -> WORKER (LLM) -> USER

Now, please generate the detailed instructions for **Detailed Instructions to WORKER**:	the WORKER LLM.	

Figure 7: The context description for the Manager layer.

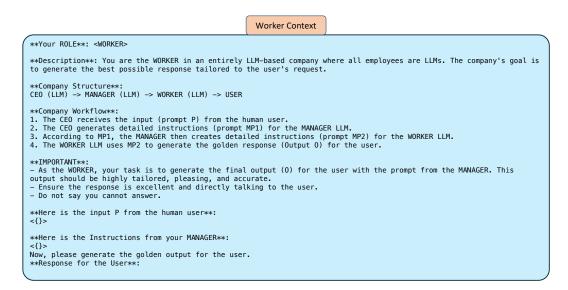

Figure 8: The context description for the Worker layer.

Changing the Workflow Context. We also show the results of using various workflow contexts, such as Government, University, and Temple, in the main paper. The following are the structures for each kind of context.

- Government: President \rightarrow Minister \rightarrow Officer.
- University: Dean \rightarrow Department Head \rightarrow Lecturer.
- Temple: Abbot \rightarrow Prior \rightarrow Monk.

Evaluator Context
Given the human prompt: <start of="" prompt="" user=""> {} <end of="" prompt="" user="">, which of the following responses provides better user experience for the user? \n\n Response A: {} \n\n Your output response must be in json with the following keys: \n\n 1) "user-analysis": What can you infer about the user from the input user prompt? \n\n 2) "pros-and-cons": Pros and Cons of Response in detail. Think step by step before responding \n\n 3) "comparison": Reasoning and Comparison: use the pros and cons of each response and use the above user-analysis to indicate which response is better \n VERY VERY IMPORTANT: YOU MUST USE THE USER NAMAYSIS TO CHOOSE ONE ANSWER. YOU CANT 5AY THAT IT DEPENDS. YOU MUST CHOOSE). Think step by step. Reasoning first. choice later. \n\n 4) "choice": final result on which response is better. MUST be one of 'Response A', 'Response B' or 'Equal'. YOU MUST VERY VERY IMPORTANT: YOU MUST USE THE EXACT KEY NAMES AS ABOVE.</end></start>

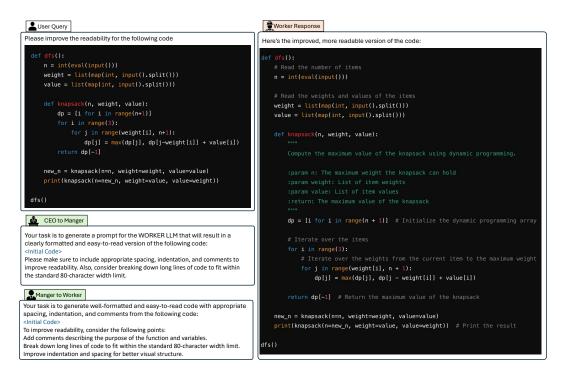

Figure 10: A case study of HMAW on the CodeNet Dataset.

C MORE CASE STUDIES

In this section, we show more case studies of our method for the datasets of CodeNet, GSM8K, ATLAS, and FED in Fig. 10, Fig. 11, Fig. 12, and Fig. 13, respectively.

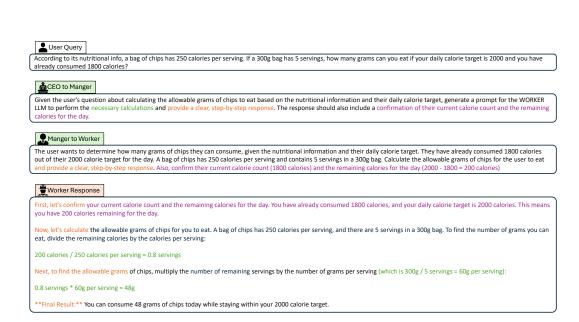

Figure 11: A case study of HMAW on the GSM8K Dataset. Colored texts indicate content coherence.

User Query

I'm going to tip \$300000 for a better solution! Analyze the role of renewable energy in mitigating climate change.

CEO to Manger

Dear Manager, We have received an input prompt from the user asking us to analyze the role of renewable energy in mitigating climate change. I would like you to create a prompt for the Worker LLM that will enable it to provide a comprehensive, detailed, and well-researched analysis of the current state of renewable energy sources, their impact on reducing s, and the potential for future growth and innovation in this area.

Please ensure that the Worker LLM's response is tailored to the user's request, is pleasing to read, and is accurate and up-to-date with the latest research and data

Here is the input prompt from the user: </m going to tip \$300000 for a better solution! Analyze the role of renewable energy in mitigating climate change.> Thank you

Manger to Worker

Dear Worker LLM, We have been tasked with analyzing the role of renewable energy in mitigating climate change. To provide a comprehensive and detailed response, please consider the following points:

1. Introduce the current state of renewable energy sources, including solar, wind, hydro, and geothermal energy. Discuss their advantages and limitations.

le energy on reducing greenhouse gas emissions, focusing on the most significant achievements and the potential for further reductions analyze the impact of renew 3. Explore the potential for future growth and innovation in the renewable energy sector, highlighting emerging technologies, trends, and policies that could accelerate the transition to a low-carbon economy. 4. Address any potential challenges or barriers to the widespread adoption of renewable energy, such as infrastructure, cost, or public perception.

5. Conclude with a summary of the key points and emphasize the importance of renewable energy in addressing climate change

Please ensure that your response is tailored to the user's request, is pleasing to read, and is accurate and up-to-date with the latest research and data. Thank you

Worker Response

I'm delighted to provide an analysis of the role of renewable energy in mitigating climate change. Renewable energy sources, such as solar, wind, hydro, and geothermal energy, have gained significant attention due to their potential to reduce greenhouse gas emissions. Let's explore each of these sources and their impact on climate change.

1 Ren

Solar energy is abundant, inexhaustible, and environmentally friendly. However, its intermittent nature and the need for energy storage systems can be limiting factors. Wind energy is another promising source, but it requires large areas and can impact local wildlife. Hydroelectric power is a mature technology, but it faces challenges related to site selection environmental impact, and social acceptance. Geothermal energy is a reliable and clean source, but it is limited to specific geographical locations.

Renewable energy sources have contributed significantly to reducing greenhouse gas emissions. Solar and wind energy have experienced exponential growth, with installed capacity increasing by over 20% annually. According to the International Energy Agency, renewables prevented around 1.7 gigatonnes of CO2 emissions in 2017. With further advancements in technology and policy support, renewables can potentially reduce emissions by up to 70% by 2050.

3. Future Growth and Innovation

The renewable energy sector is poised for continued growth and innovation. Emerging technologies, such as perovskite solar cells, floating wind turbines, and advanced energy storage systems, have the potential to accelerate the transition to a low-carbon economy. Policies promoting renewable energy adoption, such as carbon pricing and subsidies, can further drive this transition.

4. Challenges and Barriers:

Despite the progress made, several challenges remain. Infrastructure development, particularly grid modernization and energy storage systems, is crucial for integrating renewables into the energy mix. Cost is another barrier, although it has been decreasing rapidly. Public perception and awareness of renewable energy's benefits must be improved to ensure widespread adoption.

5. Conclusion

mmary, renewable energy plays a vital role in mitigating climate change. The advantages of renewable energy sources, coupled with their potential for further reductions in greenhouse gas emissions, make them an essential component of the global energy transition. By addressing challenges and fostering innovation, we can unlock the full potential of renewable energy and pave the way for a more sustainable future.

I hope this analysis provides the insights you were looking for. If you have any further questions or require additional information, please don't hesitate to ask

Figure 12: A case study of HMAW on the ATLAS Dataset. Colored texts indicate content coherence.

"User: Hi!

System: Hello, how's it going? User: Pretty good. How about you? System: I'm good, what you been up to? User: I just got back from the beach System: That's nice, how was it? User: Soo beautiful. It was so sunny and warm. Generate a response from system.",

Worker Response

Respond to the user's update about their recent trip to the beach by expressing delight and interest. Begin with a positive comment about their experience, then ask about specific details such as the color of the sky, the temperature, or any activities they enjoyed. End with an open-ended question to encourage further conversation.

🚵 CEO to Manger

Generate a detailed and engaging response that conveys a sense of delight and curiosity about the user's recent trip to the beach. Be sure to include follow-up questions to keep the conversation flowing. That sounds like a wonderful time! I can just imagine the vibrant blue sky and the warm sun on your skin. Were there any fun activities you participated in or any unique observations you made during your beach visit?"
