584 A Broader impact

We showed that when pre-training BERT on Wikipedia, the computational overhead taken to process padding tokens is roughly 50%. By eliminating this wasted computational time, the approach presented in this paper paves a way to halving the carbon footprint of training BERT-based models.

Furthermore, our approach circumvents the need for custom kernels, making the benefits of packing readily accessible to a broader audience of NLP practitioners. As such, we are hopeful the research will have a positive impact on the NLP community, and do not see any disadvantage of using this approach.

592 The benefit of our algorithm is based on two assumptions: A skewed length distribution in the training dataset and a hardware setup that trains efficiently on a fixed batch size. If *efficient training* 593 is possible, with a variable batch size approaches like FasterTransformer and the fairseq sorted batch 594 approach will result in the same or even larger benefits (due to smaller self-attention matrices). If the 595 dataset is generated differently like in GPT models 4 and RoBERTa (FULL-SENTENCES) 16, all 596 sequences will be at full length and sequences cannot be concatenated and there is indeed no benefit 597 in packing sequences. However, strategies that reach full sequence length usually combine segments 598 from different unrelated document sources which can result in reduced performance. Even in the 599 normal BERT model, there might be this contamination between segments from different documents. 600 Our paper introduced an approach to avoid the contamination between sequences. However, the same 601 approach could also be applied to avoid contamination between segments and it remains future work 602 to explore its benefits beyond BERT pretraining. 603

Future work would need to investigate the applicability of packing on text produced by different 604 cultures and in different languages. We have already shown that the speed-up resulting from using 605 our methods does not only occur when pre-training BERT on Wikipedia but also on other datasets 606 such as SQuAD and GLUE. Furthermore, the sentence length distribution of the original English 607 language text shows similar characteristics. Our research leads us to believe that compressible 608 distributions arise naturally in language tasks and beyond, for instance in DNA sequence lengths [40], 609 protein lengths [39], and speech (Section M). Many such sequence modelling workloads are based 610 on variations of the BERT/transformer architecture and would therefore easily benefit from our 611 acceleration. 612

Failures in NLP can have a big impact on society; many technologies, such as Alexa, Siri, and Google Home, rely on them. Whilst any errors arising from our approach can be avoided, one potential source of error comes from the implementation. Both the attention mask and the per-sequence loss need to be modified to support packing. These changes are significantly smaller than those required by custom kernels, however they may still be time consuming to implement and debug. To help mitigate the risk of any implementation errors, we share our reference implementations of the required changes in the appendix.

620 **B** Reproducibility Statement

All code for the packing algorithms is available in the appendix (Section T) and is directly linked to our GitHub page to simplify the download and usage. We even provide code for different variants and the histograms of sequence length for different datasets that got tokenized for BERT training of fine-tuning.

To generate the learning curves, our public submission to MLPerfTM could be used and we are preparing further code releases in other frameworks. To encourage the use of the adjustments of models for packed sequences, we additionally provide detailed explanations and code snippets in TensorFlow.

⁶²⁹ Detailed mathematical formulas (Section E and F), a theorem proof (Section D), and complexity ⁶³⁰ calculations (Section G) are provided in this appendix to support our claims in the paper in full detail.

631 C Related work

The most obvious way to reduce the extent of padding in the dataset is to group samples by size 632 before batching (SORT), i.e., process the shorter samples together and longer samples together. 633 BERT is pre-trained in two phases, where the first phase uses sequence length 128 for 900K steps 634 and the second phase uses sequence length 512 for 100K steps. However even by splitting the 635 training in this way, the wasted compute due to padding is approximately 20% (see Figure 1). Other 636 examples of this "sorted batching" approach can be found in Faster Transformer [21], lingvo [28] 637 fairseq [22], and RoBERTa [16], which group samples of similar size together in one batch and fill 638 up with padding only to the maximum length in this batch. This approach can be highly efficient 639 in cases where the dataset length is multiple orders of magnitude larger than the batch size and the 640 number of different sequence lengths. Despite its high computational efficiency, this approach has 641 multiple drawbacks. We outline these below and propose an alternative which maintains the high 642 efficiency, while also circumventing the downsides. Firstly, sorting the data can reduce the overall 643 convergence speed when the batch size is large because it violates the i.i.d. assumption on the data 644 distribution [2] [18]. Secondly, processing batches with shorter sequence lengths under-utilizes the 645 compute compared to running the same batch size with a longer sequence length. For GPUs, a 646 common heuristic to mitigate this effect is to adjust the batch size to keep the number of processed 647 tokens near constant [22] [6]. In general however, the relationship between the sequence length 648 649 and the optimum batch size is more complex and maximizing compute utilization can require the 650 model to be sharded differently across multiple accelerators. Avoiding this, often manual process, 651 is important for ease of use and the portability of methods across different hardware architectures. Thirdly, modern NLP applications are optimized and compiled for fixed tensor sizes using tools such 652 as XLA [34, 9], which provides a $\approx 7x$ acceleration for BERT in MLPerfTM [17] compared to the 653 non-XLA baseline [34]. Changing the sequence length or batch size requires re-optimization of 654 the computational graph and recompilation of the program for the new tensor shapes. For complex 655 models such as BERT, optimization and recompilation take a non-negligible amount of time. Even if 656 one pre-compiled and cached all combinations of batch size and sequence length, the kernels would 657 still need to be re-uploaded to the device every time the shapes change. Depending on how frequently 658 the tensor shapes change, the overhead from switching kernels adds up. To avoid these issues, it is 659 preferable (and common) to work with fixed tensor shapes for the entire duration of the training run. 660

More advanced approaches for reducing the padding overhead rely on custom computational kernels. 661 Loosely these are referred to as "un-padding" approaches. In Effective Transformer [5], the input 662 batch is provided as a padded matrix but padding values are dynamically removed and restored during 663 different calculation stages. While un-padding implementations are highly sophisticated and are able 664 to completely circumvent the processing of padding tokens, they introduce a significant overhead 665 666 due to the multiple GPU kernel launches (i.e., one kernel per sequence rather than one kernel per batch). Additionally the time to process each batch will fluctuate depending on the sequence lengths 667 in each batch, i.e., batches with only shorter sequences will typically be processed faster. When 668 working with more than one accelerator, this variability in throughput results in all devices in the 669 cluster waiting for the device with the most compute intensive batch to finish processing. As such, 670 un-padding approaches are not appropriate for deployment on large clusters. The "packing" based 671 approach introduced in this paper offers significant advantages over un-padding approaches. Firstly, 672 packing is implemented directly at the framework level and requires no additional custom kernel 673 674 implementations. Secondly, the processing time for each batch is independent of the content of the batch, allowing the packing based approach to maintain the same speed-up whether running on a 675 single device or thousands. 676

While we demonstrate the effectiveness of packing specifically on the Wikipedia dataset, packing 677 SQuAD [25] or GLUE datasets [31, 30] for BERT also leads to significant speed-ups (some in excess 678 of 9x) (Sections K and L). The effectiveness of packing is a result of both the length distribution 679 of the documents in the source datasets as well as the different text preprocessing steps for BERT 680 **[8]**. The use of bi-directional self-attention in BERT implies that the input sequences should contain 681 complete sentences. If a sentence is abruptly cut short, the hidden state on other (preceding) tokens 682 683 in the sequence will be affected. Language models with causal attention (only attending to previous tokens in the input) do not have this issue to the same degree. For such models, if a sequence is 684 cut short at an arbitrary token, the other tokens (which occur earlier in the sequence) will not be 685 affected. This ability to cut sequences arbitrarily completely trivializes the packing problem for 686 models based on causal attention. For instance, GPT-3 [4] is trained with a maximum sequence 687

length of 2048 where a single sequence may contain multiple segments of sentences separated by a 688 special end of segment token. The last segment in each sequence is simply cut to meet the sequence 689 length requirement making the packing problem trivial and avoiding any padding. In the interest 690 of computational efficiency GPT-3 does not mask the attention between different segments in a 691 sequence. In contrast, the packing approach presented in this paper introduces a mask in the attention 692 layer (see Section [3.2.2]) to prevent cross-contamination between examples in a pack. Note, we mask 693 694 the interaction between different sequences and not between different sentences or segments in the same sequence. This ensures that the characteristics of the original dataset and model are matched 695 as closely as possible. RoBERTa and many other models in production like T5 [24] use a similar 696 packing approach as GPT-3, combining full sentences/sequences with GREEDY packing (first come 697 first concatenate) and also separation tokens or additional padding. The RoBERTa ablation study 698 shows that mixing of sentences from different documents reduces accuracy, but it is used nonetheless 699 for load balancing reasons which indicates that sorted batching is not sufficient. 700

There might be hidden code snippets as in the deprecated tensor2tensor library that seems to implement the same attention masking mechanism as we propose. However, these lack a sufficient documentation, testing, evaluation, ablation, and communication to the research community to be considered state of the art in NLP research. More general, to the best of our knowledge and the knowledge of many other engineers and researchers that we were in contact with, there is no other research work that focuses on packing in NLP.

707 D Theorem on LAMB hyperparameter correction heuristic

With packing, the effective batch size changes and hence hyperparameters of the LAMB optimizer 35need to be adjusted. For a packed dataset with a packing factor p, we update the decay parameters as: $\overline{\beta_1} := \beta_1^p$, $\overline{\beta_2} := \beta_2^p$. For instance if $\beta_1 = 0.81$ for the un-packed dataset, then for a packed dataset with an average of 2 sequences per sample one should use a value of $0.81^2 \approx 0.66$ instead. Assuming no or only minor changes in gradients and p being a natural number, we can prove that this heuristic is the exact solution to make sure that momentum and velocity in LAMB are unaffected by packing. This can be proven by mathematical induction. Note that $p \ge 1$ by definition.

Theorem D.1. For any $p \in \mathbb{N}$ and assuming that respective gradients on a batch of b random samples are (approximately) the same, choosing

$$\overline{\beta_1} := \beta_1^p \tag{1}$$

$$\overline{\beta_2} := \beta_2^p. \tag{2}$$

as hyperparameters in the LAMB optimizer ensures that the momentum and velocity after p separate update steps are the same as with one packed update step with $p \times b$ samples.

719 Proof.

720 • *Base Case*:

For p = 1 the left and right side of the equation are the same which matches exactly the unpacked case. Hence, the theorem holds for p = 1.

• Inductive hypothesis: Suppose the theorem holds for all values of p up to some $k, k \ge 1$.

- Inductive proposition: The theorem holds for p = k + 1.
- Proof of the inductive step: Let l be the loss function, w_t the weight vector after t updates, and x_1^t, \ldots, x_b^t the respective underlying data to calculate the gradient g_t . For a single update step in LAMB with batch size b samples, we compute the gradient

$$g_t = \frac{1}{b} \sum_{i=1}^{b} \frac{\partial l}{\partial w} (x_i^t, w^t).$$
(3)

Since $g_1 \approx g_2 \approx \ldots \approx g_{k+1}$, We have with the inductive hypothesis and the definitions in LAMB:

$$m_k = \beta_1^k m_0 + (1 - \beta_1^k) g_1 \tag{4}$$

$$v_k = \beta_2^k v_0 + (1 - \beta_2^k) g_1^2 \tag{5}$$

Now we can calculate (with $g_1 \approx g_{k+1}$)

$$m_{k+1} = \beta_1 m_k + (1 - \beta_1) g_{k+1} \tag{6}$$

$$\approx \beta_1 \left(\beta_1^k m_0 + (1 - \beta_1^k) g_1 \right) + (1 - \beta_1) g_1 \tag{7}$$

$$=\beta_1^{k+1}m_0 + (1-\beta_1^{k+1})g_1 \tag{8}$$

The calculation for v_k is the same. As reference for a packed update with p = k + 1 with $\overline{\beta_1}$ and $\overline{\beta_2}$, we would get

$$g = \frac{1}{pb} \sum_{j=1}^{p} \sum_{i=1}^{b} \frac{\partial l}{\partial w}(x_{i}^{j}, w^{1}) = \frac{1}{p} \sum_{j=1}^{p} \left(\frac{1}{b} \sum_{i=1}^{b} \frac{\partial l}{\partial w}(x_{i}^{j}, w^{1})\right) \approx \frac{1}{p} \sum_{j=1}^{p} g_{1} = g_{1} \quad (9)$$

since we are calculating gradients over *b* samples which are assumed to be approximately
 the same. Consequently, the updates for momentum and velocity would be

$$\overline{m_k} = \overline{\beta_1} m_0 + (1 - \overline{\beta_1}) g_1 \tag{10}$$

$$\overline{v_k} = \overline{\beta_2} v_0 + (1 - \overline{\beta_2}) g_1^2. \tag{11}$$

 \square

Hence, $\overline{\beta_1} = \beta_1^{k+1}$ and $\overline{\beta_2} = \beta_2^{k+1}$ is required to map to the formula with the consecutive updates (for the same amount of data).

• Conclusion: The theorem holds for any $p \in \mathbb{N}$.

738

Since we proved that the formulas $\beta_1 := \beta_1^p$, $\beta_2 := \beta_2^p$. hold for all $p \in \mathbb{N}$, $p \ge 1$, it is safe to assume that it is an appropriate heuristic for all $p \in \mathbb{R}$, $p \ge 1$.

741 E Un-padding scaling estimate

To demonstrate the severity of the load-imbalance issue in Section 4.4 we consider the scaling of an 742 un-padding approach with a per-device batch size of 32 running on eight devices [20]. From there, 743 we readily extrapolate the performance to both larger and smaller cluster sizes by fitting a Gumbel 744 distribution to the observed processing times as described in this section. On a single device with 745 batch size 32 un-padding outperforms packing and exceeds the theoretical upper-bound for packing. 746 As the number of devices increases to two or more, the proposed packing approach outperforms the 747 748 dynamic un-padding approach. On a cluster with 32 accelerators the speed-up from un-padding drops to 50% and with 2048 devices the speed-up is only 30%. In contrast, the speed-up due to packing 749 is independent of the number of accelerators and stays at 1.913. Switching to a smaller batch size 750 would reduce the load-imbalance issue to some extent, but would also result in under-utilization of 751 the available memory and compute. 752

Firstly, we retrieve the per-batch processing time for an un-padding implementation running pretraining on the Wikipedia dataset from [20]. These processing times were obtained using 8 GPUs each with a per-device batch size of 32. We also retrieve the throughput numbers for the same system running with padding from [44] and use that as the baseline to compare the un-padded throughput against.

The throughput on the 8 GPU system is effectively limited by the slowest of the eight batches being processed in parallel. The Gumbel distribution is particularly suited to modelling the maximum or minimum value of a fixed size collection of i.i.d. samples (in this case batches). We observe that on & GPUs the throughput (i.e. speed-up) distribution indeed closely resembles a Gumbel distribution with $\alpha_1 = 1.6$ and $\beta_8 = 0.13$ as shown in Figure 6

We can extrapolate the performance on the 8 GPU system to larger clusters by recognizing that the processing time for each cluster is effectively determined by the slowest batch being processed. Specifically, we could randomly sample (without replacement) two processing times for the 8 GPU system, and record the max of the two as the processing time for a system of 16 GPUs. However, this simple approach is too sensitive to outliers in the data and would result in an under-estimate of the performance of un-padding on large systems. We mitigate the effect of outliers in the data

Figure 6: Left: Speed-up from un-padding on 8 GPUs closely resembles a Gumbel distribution. Right: statistical estimate of speed-up distribution on a 1 GPU system running un-padding

by avoiding directly sampling the processing times. Instead, we fit a Gumbel distribution to the processing times of a single batch of size 32 running on one GPU. To perform the fit, we observe that the cdf on one GPU (P_1) is related to the cdf on 8 GPUs (P_8) through [41] (section 1.3):

$$(1 - P_8(s)) = (1 - P_1(s))^8$$
(12)

In other words, if the speed-up on the cluster is larger than s, this implies that the speed-up on

every GPUs in the cluster was at least s. Assuming P_1 is Gumbel and given the 8 GPU Gumbel parameters α_8 and β_8 , we need to fit two parameters, α_1 and β_1 . Consequently for the median

775 $(s = \alpha_8 - \beta_8 \ln(\ln(2)), P_8(s) = 0.5)$, we have:

$$0.5 = (1 - P_1(\alpha_8 - \beta_8 \ln(\ln(2))))^8.$$
(13)

And since P_8 is Gumbel, we also have an equation for the mode $(s = \alpha_8, P_8(s) = e^{-1})$:

$$(1 - e^{-1}) = (1 - P_1(\alpha_8))^8.$$
⁽¹⁴⁾

We solve these two non-linear equations simultaneously using the standard SciPy optimization package.

Listing 1: Infer Gumble distribution parameters.

```
779
       import numpy as np
      from scipy import stats, optimize
alpha_8 = 1.6038
780
781
782
       beta_8 = 0.1288
      def g(x):
783
          alpha_1, beta_1 = x
784
785
          dist = stats.gumbel_r(loc=alpha_1, scale=beta_1)
          # Equations for median and mode
786
787
          median = alpha_8 - beta_8*np.log(np.log(2))
788
           equation1 = 0.5 - dist.sf(median)**n_gpu
789
          mode = alpha 8
790
           equation2 = (1-np.exp(-1)) - dist.sf(mode)**n_gpu
791
           return (equation1**2 + equation2**2)
792
793
       res = optimize.minimize(g, [alpha_8, beta_8], method="Nelder-Mead")
794
      alpha_1, beta_1 = res.x
```

The resulting estimated speed-up Gumbel distribution for a single device has $\alpha = 1.94$, $\beta = 0.108$ and is shown in Figure 6 [right]. To simulate the performance of a cluster of size *n* with a batch size of 32 per device, we take the minimum over *n* samples from this distribution. Repeating this process to generate many samples allows us to estimate the expected speed-up for any given cluster size. Unfortunately, we cannot make any statistical inference about the processing times of individual sequences since the data is only provided at the granularity of 32 sequences per batch, and it is not clear how much of the computation is done in parallel and how much in serial.

802 F Technical background on packing

803 F.1 Canonical packing problem

The bin packing problem deals with the assignment of items into bins of a fixed capacity such that the 804 number of utilized bins is minimized. In the canonical formulation of the packing problem a vector 805 s(i) of length n is used to represent the items being packed, where s(i) denotes the length of the i-th 806 sequence/item. The allocation of items into bins is tracked through the assignment matrix B, where 807 $B_{ij} \in \{0,1\}$ states whether the i-th sequence should be placed into the j-th bin. In the worst case 808 scenario, every item is assigned to its own bin, thus $B \in \mathbb{R}^{n \times n}$. Notably, s grows linearly in the 809 number of sequences/items being packed and B grows with the square. To mask out unused bins 810 $y_i \in \{0, 1\}$, denotes whether the j-th bin is being used. The optimization objective is to minimize the 811 sum of y_i while making sure to assign each s_i to exactly one bin and not exceeding the maximum 812 bin capacity s_m for each bin. This problem formulation is well known as bin packing [14]. 813

$$\min_{y \in \{0,1\}^n, B \in \{0,1\}^{n \times n}} \sum_{j=1}^n y_j \qquad \text{Minimize the number of bins.}$$
s.t.
$$\sum_{j=1}^n b_{ij} = 1 \quad \forall i \qquad \text{Assign each length/sequence to only one bin.}$$

$$\sum_{i=1}^n s(i)b_{ij} \leq s_m y_j \quad \forall j \qquad \text{Cumulative length cannot exceed capacity.}$$
(15)

Bin packing is a strongly NP-complete [14] problem. Producing an exact and optimal solution is possible with a variety of existing algorithms, for example with the branch-and-cut-and-price algorithm [37]. However, given that we want to apply it for very large n (16M for the Wikipedia dataset) an approximate approach is required.

818 F.2 Approximate bin packing problem

Approximate packing approaches are divided into online and offline algorithms [12]. Online algo-819 rithms process incoming sequences one-by-one in a streaming fashion, whereas offline algorithms 820 have a holistic view of all samples to be packed but typically still operate on a per sample basis. 821 This results in best case time and memory complexities of at least $O(n \log(n))$ and solutions that 822 can sometimes be far from optimal, especially for the online algorithms which do not have access 823 to a holistic view of the datasets. The simplest online approach (next-fit) would be to keep a single 824 open bin at any given time. An incoming sequence is added to this open bin if it fits, otherwise the 825 bin is closed (can never be appended to again) and a new one is opened to accommodate the new 826 sequence [12]. In the case of the Wikipedia pre-training dataset almost 25% of the sequences are of 827 length 512, which makes this approach very inefficient since bins would frequently be closed because 828 829 the incoming sequence did not fit. More specifically, this approach is not able to efficiently combine 830 one long sequence with one shorter sequence, when the number of long sequences is large. The 831 algorithms that come closest to the approaches proposed in this paper are the online harmonic-k algorithm [15], which creates harmonic sized bins for the assignment decision, and the offline Modified 832 First Fit Decreasing method [13, 36], which sorts the data, groups it into 4 size categories and defines 833 a strategy adjusted to these sizes. 834

In our approaches, we make three major simplifications. We make the problem of bin packing less dependent on n by operating on the histogram of sequence lengths with bin size 1. Hence, we replace s(i) by its histogram b and the bin assignment y, B by a mixture of strategies x, where the set of all available packing strategies is modeled as the matrix A (see also Section F.4.2).

Then, we do not solve the full packing problem but focus on a fixed packing depth (in other words the well known 3-partition problem). Last but not least, we solve the limited depth packing problem only approximately either with a non-negativity-constrained linear least squares [3] (NNLS) followed by rounding to nearest integer solution or by applying Worst-Fit [13, 36] to the histogram, sorted from largest to smallest (in contrast to using an unsorted dataset). An exact solution would not be appropriate, since the 3-partition problem is strongly NP-complete [38] as well.

845 F.3 Definitions

In this section, we standardize the terms used throughout our methods. Firstly, the terms *pack* and *bin* 846 may be used interchangeably. Secondly, the presented packing schemes impose a limit on how many 847 sequences can be packed into any given bin. This limit is referred to as the maximum packing depth. 848 For simplicity, we require the different sequence lengths in a pack to always add up exactly to the 849 bin capacity s_m (we can always generate a padding sequence of just the right length to fill-up the 850 bin). A packing strategy is a sorted list of sequence lengths, for example [5, 7, 500], such that the 851 total sequence length is no more than s_m and the number of sequences in the pack does not exceed 852 the maximum packing depth. The output of a packing scheme is typically as set of packing strategies 853 and the corresponding repeat count for each strategy stating how many times each strategy should 854 855 be repeated in order to cover the entire dataset. The strategy *repeat count* is also referred to as the *mixture* of strategies. The objective of the packing algorithm is to jointly design a set of packing 856 strategies and their repeat counts, such that the amount of *padding* is (approximately) minimized. 857 The presence of *padding* in the packs can either be implicit or explicit. For instance for $s_m = 512$ 858 the strategy [2, 508] has an implicit padding of 2 (needed to fill the pack up to the s_m). Alternatively, 859 the strategy repeat count may over-subscribe a particular sequence length leading to explicit packing. 860 For instance constructing a pack of [4, 508] may require a new *padding* sequence of length 4 be 861 constructed, if there are not enough sequences of that length in the dataset. The packing algorithms, 862 we present, use both representations. 863

864 F.4 Non-negative least squares histogram-packing

The first algorithm proposed in this paper is suitable for settings where it is desirable to achieve a high packing efficiency with a limited packing depth. The algorithm is deterministic and has three major components described in Sections [F.4.1] F.4.2] and [F.4.3]

868 F.4.1 Enumerating packing strategies of fixed packing depth

Listing all unique ways of packing up to a maximum packing depth can be achieved through dynamic 869 programming. We only consider packing at most up to 3 sequences per pack. This is the smallest 870 packing depth that can eliminate the need for most padding on the Wikipedia dataset. Increasing the 871 depth to 4, increases the size of the packing problem drastically and yields no throughput benefit,² 872 With only two sequences, packing would be not as efficient since the distribution on sequence length 873 is not symmetric. We use dynamic programming to enumerate all feasible ways/strategies that up 874 to M sequences of length 1-512 can be packed into a bin of length 512. For example, a packing 875 strategy may be [512] or [6, 506] or [95, 184, 233]. To avoid listing the same strategy multiple times, 876 we enforce the sequence lengths within a pack to occur in sorted order, for example, [95, 184, 233] is 877 equivalent to [184, 95, 233] and should only be listed once. This reduces the search space as well as 878 879 the space of potential solutions by a factor of 6 approximately and thus significantly accelerates the optimization process. If you had the same strategy repeated 6 times instead of having just one instance 880 of that strategy with weight X, you will have six instances with weight x/6 (for example, or any 881 other distribution). This would conflict with integer rounding of the solutions and with convergence 882 of optimization algorithms. 883

884 F.4.2 Constructing the packing matrix

The number of rows in the packing matrix is equal to the number of different sequence length 885 categories. For instance, if we are using a granularity of 1 token to distinguish between different 886 sequence lengths, then there are "maximum sequence length" rows. Each column of the matrix 887 corresponds to a valid packing strategy (given the depth of packing). An example packing matrix 888 for fitting up to 3 sequences into sequence length 8 is given in Table 4. Each column of the matrix 889 represents a packing strategy. For instance, the first column represents the strategy [1, 1, 6] of 890 packing two length-1 sequences and one length-6 sequence together to form a pack of length 8. The 891 number of strategies (and columns in the matrix) is discussed in Section **G** For a packing depth of 3 and maximum sequence length, we obtain around $\frac{s_m^2+6s_m+12}{12}$ strategies. For depth 4, around 892 893

894 $\frac{s_m(s_m+4)(2s_m+1)}{288}$ more get added.

²For data distributions that are more skewed than Wikipedia this might look different.

Table 4: Example packing matrix for sequence length 8. Columns represent different kinds of packs. Rows represent the number of sequences in these packs with a certain length. The last column represents a pack with only a single sequence of length six.

2	1	1	1	0	0	0	0	0	0
0	1	0	0	2	1	1	0	0	0
0	0	1	0	0	2	0	1	0	0

0	1	0	0	0	0	0	1	0	0
1	0	0	0	0	0	1	0	0	0
0	0	0	1	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0	1

895 F.4.3 Solution of the NNLS approximate packing problem

A solution of the packing problem is the mixture of packing strategies x that minimizes the amount of padding in the packed dataset. We solve directly for the mixture (positive real numbers) and recover the padding as the negative portion of the residual (see Section [F.4.4]).

$$\min_{x \in \mathbb{R}^m} \|A \cdot x - b\|^2$$

s.t. $x > 0$ (16)

The solution vector x will represent the mixture of the columns of A, in other words the mixture of valid packing strategies such that $A \cdot x$ is as close as possible (in the least squares sense) to the histogram of sequence lengths b. We obtain a solution with a non-negative least squares implementation [42] 46] Interestingly in the case of sequence length 512 only 634 out of the 22102 available packing strategies of depth up to 3 are used (3%).

904 **F.4.4** Padding as the residuals of the packing problem

⁹⁰⁵ We compute the residuals of the least squares solution (after rounding the mixture to integer) as:

$$r = b - A \cdot round(x) \tag{17}$$

The negative portion of the residuals represents sequences that we are "short". That is, there is a deficit of those sequences and we are over-subscribing to them. The positive portion of the residuals represents sequences which have failed to be packed. Typically, there is a deficit of short sequences

and a surplus of long sequences as demonstrated by the following plot.

Figure 7: Visualization of the residual of the NNLS packing problem

In total, there are n = 16'279'552 sequences in the Wikipedia pre-training dataset. After the non-negative least squares packing (and rounding to integer solution) there are 56'799 unpacked sequences left un-packed (about 0.352%). The residual on sequence lengths 1 to 8 are ⁹¹³ [-4620, -4553, -4612, -4614, -3723, -3936, -3628, -3970]. These negative residuals imply ⁹¹⁴ that we need to add this many sequences of their corresponding sequence length to realize the mixture ⁹¹⁵ of packing strategies. In total the first iteration introduces 7.9410^6 tokens of padding. In contrast ⁹¹⁶ large sequence lengths have a positive residual (a surplus of unused sequences). For sequence lengths ⁹¹⁷ 504 to 512 the values are [3628, 3936, 3724, 4613, 4612, 4553, 4619, 0]. Note that sequence length ⁹¹⁸ 512 has a residual of 0 since they do not need packing. Intermediate sequence lengths typically have ⁹¹⁹ non-zero (but much smaller) residuals.

The detailed code for the algorithm is provided in Listing 2

921 F.4.5 Residual weighting

A natural extension of the non-negative least squares problem introduced in Section F.4.3 is to weight the residuals on different sequence length differently.

$$\min_{x \in \mathbb{R}^m} \| (wA) \cdot x - (wb) \|^2$$

s.t. $x \ge 0$ (18)

We should not significantly penalize a deficit in short sequence lengths (smaller than 8 tokens) as adding up to 8 tokens of padding is not much overhead. Similarly, a surplus in long sequences is not worrisome because the amount of padding needed to achieve a sequence length of 512 is small. Reducing the weight of the residual on the first 8 tokens to 0.09 leads to the following residual plot shown on the right in Figure 8. In this case the residual is almost entirely shifted to the shorter sequences and the positive residual on the longer sequences has virtual disappeared.

Figure 8: Visualization of the weighted residual of the NNLS packing problem

930 F.5 Discussion of residual weight choice

This section discusses the choice and effect of the weighting parameters in the NNLSP packing 931 algorithm. To simplify the problem of selecting reasonable defaults for the residual weights, we 932 use just two parameters to completely describe the weights: an "offset" parameter and a "weight" 933 parameter. Originally, all sequence length residuals are given the same weight of 1. This results 934 in a packing with leftover long sequences, because there are not enough short sequences to pack 935 them with. To reduce the residual on long sequences, we could either increase the residual weight on 936 long sequences or reduce the weight on short sequences. We chose to reduce the weight on short 937 sequences. Specifically, sequence lengths up to the "offset" length have a reduced "weight". The 938 other residual weights stay at 1. 939

To start, we chose an offset of 8 tokens, which is the smallest power of 2 for which there are examples 940 in the Wikipedia dataset. We decrease the weight on sequences shorter than the "offset" from 1 to 0.9941 to 0.09 to see which order of magnitude is the most appropriate. On visual inspection (looking at the 942 residual plots as in Figure 8, we found that 0.9 still left too many long sequences unpacked. So, we 943 reduced the weight a further order of magnitude to 0.09. This seemed sufficient to encourage nearly 944 all long sequences to pack. While visual inspection helps in understanding how many long/short 945 sequences are leftover, we are also interested in the impact the weights have on the overall efficiency 946 of the packing. 947

Without any weighting, we get 99.746359% efficiency, whereas the weighted approach results in 948 99.746274% efficiency. Hence, we conclude that the impact of the weights on the packing efficiency 949 is very limited. Additionally, using an "offset" length of 4, resulted in similar numbers, for the full 950 range of weights from 0 to 1. Using a weight of 0 for an "offset" length of 8 resulted in insignificantly 951 higher efficiency of 99.7519%, whereas using an "offset" length of 16 reduces performance to 952 99.38964%. A weight of 0 implies that the residual on those lengths can be safely ignored, i.e., the 953 packing algorithm can thus add as many short sequences as it chooses without any penalty. It is 954 955 very interesting that this does not significantly impact the packing efficiency, and can even have a slightly positive impact. However, increasing the "offset" length further significantly decreases the 956 performance with weight 0. Keeping the weight at 0.09 and increasing the length reduces performance 957 slightly, for example with 99.53% at length 256 and 99.728% at length 16. 958

For our Squad analysis, weighting improved the efficiency slightly from 96.94% to 97.38%. Fine
 tuning further with direction grid search, delivered a local optimum of 98.767% efficiency with length
 64 and weight 0.002.

Overall the influence of different residual weights on the packing efficiency (and the acceleration factor) is less than 1%. This might differ from application to application, but it shows that we are able to use the residual weights to achieve secondary targets (like not having leftover long sequences) without significantly compromising the packing efficiency.

G G Complexity analysis of the proposed packing approaches

Since approximate packing algorithms have a complexity of at least $O(n \log(n))$ and we would like to be able to tackle datasets with 2K million samples, we will discuss the complexity of our packing algorithms in this section. The complexity depends on the maximum sequence length s_m , the number of samples n, and the packing depth d.

To create the histogram, we have to iterate over the data once (O(n)). Our histograms will be binned by size 1, meaning one bin for each sequence length. Hence, a dictionary can be generated $(O(s_m))$ and used for the sorting (O(1)). The respective histogram vector has dimension s_m .

974 G.1 Complexity Analysis of non-negative least-squares histogram-packing

For a packing depth of one, there is only the strategy $[s_m]$. For a packing depth of two, we add the strategies $[1, s_m - 1], ..., [s_m - \lfloor \frac{s_m}{2} \rfloor]$ which results in an additional $\lfloor \frac{s_m}{2} \rfloor$ potential strategies. Following the dynamic programming approach, the number of possible additional strategies of depth three can be calculated with

Note that for $s_m = 512$ the approximation is exact. This means that our strategy matrix A has the 979 dimensions $s_m \times \left(\left[\frac{s_m^2}{12} \right] + \left\lfloor \frac{s_m}{2} \right\rfloor + 1 \right)$. Overall, this leaves us with a space complexity of s_m^3 since A is larger than w, x, and b. So it contains 11'316'224 numbers which is still much smaller than 980 981 n. Note that the original data matrix B had n^2 entries, which all needed to be optimized together 982 with the *n* bin assignments *y*. We now have only $\left[\frac{s_m^2}{12}\right] + \lfloor \frac{s_m}{2} \rfloor$ free variables in the strategy vector *x*. Also note that *A* can be precomputed when s_m is known and is independent of the number of 983 984 samples. Given a problem matrix with dimension $i \times j$, Luo et al. [43] indicate that the asymptotic 985 complexity of most solution approaches is $O(ij^2)$, whereas they propose an O(ij) solution. Since 986 we use the standard SciPy implementation [42], our estimated total time complexity for NNLSHP is 987 $O(n + s_m^5).$ 988

For $s_m = 2048$, the estimate would be 350'540 potential strategies which is still far less than the number of samples. For packing depth 4, we calculate [48]:

$$\sum_{k=1}^{\lfloor \frac{s_m}{4} \rfloor} \sum_{j=k}^{\lfloor \frac{s_m-k}{3} \rfloor} \sum_{i=j}^{\lfloor \frac{s_m-j}{2} \rfloor} 1$$

$$\approx \sum_{k=1}^{\lfloor \frac{s_m}{4} \rfloor} \sum_{j=k}^{\lfloor \frac{s_m-k}{3} \rfloor} \frac{s_m-k+2-3j}{2}$$

$$\approx \sum_{k=1}^{\lfloor \frac{s_m}{4} \rfloor} \frac{1}{12} (s+4-4k)(s+3-4k)$$

$$\approx \frac{1}{288} s(2s^2+9s+4)$$

$$= \frac{1}{288} s(s+4)(2s+1)$$
(20)

So with $s_m = 512$, there would be around 940K strategies. In our implementation, this number of strategies would be too high to create the problem matrix. One alternatives to simplify would be to

not use the exact length of sequences but to only consider even numbers for the sequence length and round up. That way arbitrary sequence length could also be handled and the limiting factor would be the complexity of the attention layer in BERT which does not scale well with the sequence length.

996 G.2 Complexity Analysis of shortest-pack-first histogram-packing

The complexity calculation of SPFHP is straightforward. We go over the whole data once for the 997 histogram sorting. Next, we iterate over each of the s_m bins in the histogram. Lastly, we iterate over 998 all strategies that were encountered so far. It can be proven that, at each iteration, the number of 999 strategies can be maximally increased by one. In each step, we potentially add a sequence to existing 1000 strategies but a new strategy is opened up only in the final step, when we either create a new strategy 1001 or we split one of the existing strategies into two. Hence, the number of strategies is bounded by s_m 1002 and the overall time complexity is bounded by $O(n + s_m^2)$. The space complexity is $O(s_m^2)$ since we 1003 need to store up to s_m strategies with maximum s_m counts for different sequence length. 1004

1005 H Performance Comparison to GREEDY Packing in T5

T5 [24] is normally trained on the C4 dataset. However, to give an idea of the difference in packing efficiency and acceleration compared to our newly introduced algorithm, we can analyse the performance of greedy aggregation of samples on our given Wikipedia dataset.

We take the histogram and cast it back to a list of different sequence lengths since this is all that matters for analysing packing behaviour. Next, we randomly shuffle the dataset and iterate with the greedy aggregation algorithm multiple times to account for randomness. We iterate sequence by sequence and combine them provided the maximum sequence length of 512 is not yet reached. If it is exceeded, the packed sequence is considered finished and a new sequence is started.

The greedy packing algorithm itself takes a bit more than 10 seconds, since we are operating on single sequences and not histogram counts. The efficiency of this approach is 78.24% (standard deviation of 0.005) compared to our 99.75% for NNLSHP. The respective acceleration would be around 1.566xcompared to our 2x. With respective separator tokens, the performance decreases around 0.13%for one separator token and 0.27% when two separator tokens are required between two sequences. Following the brief documentation at tensor2tensor [link], two separator tokens would be expected in the T5 processing.

In addition to the packing preprocessing, our paper proposes, rather than using separator tokens, to instead modify the masking of the attention matrix during training. The RoBERTa paper shows that avoiding contamination of sequences from different documents can consistently improve downstream F1 scores by 0.35%.

1025 I Impact of NSP loss

When running packed BERT base without the NSP loss but keeping everything else the same, we observed that downstream performance on SQuAD reduced the F1 measure by 1.31% and EM by 1.15%.

For the packing in approaches like RoBERTa or T5, it is crucial that there is no NSP loss because 1029 that would circumvent putting arbitrary sequences together in contrast to our approach that can 1030 handle multiple sequences from different documents without cross-contamination. Liu et al. 16 1031 argument that NSP can be omitted because "removing the NSP loss matches or slightly improves 1032 downstream task performance". In their experiments, they compare the normal BERT setup with 1033 NSP ("SEGMENT-PAIR") to the "DOC-SENTENCES" approach, where there is no NSP and data 1034 1035 in one sequence comes only from one document. For the "SEGMENT-PAIR" approach, the paper does not address, how much padding tokens are still present. Assuming, it is around 40%, their 1036 correction in batch sizes for each step would result in a significant increase in training steps for the 1037 "DOC-SENTENCES" approach. It is well known that BERT performance increases with longer 1038 1039 pretraining time. Our results indicate that NSP loss might be still relevant, depending on the dataset 1040 generation process. With our approach, we can get the acceleration benefits of T5 and RoBERTa while keeping the predictive performance by avoiding cross-contamination. 1041

1042 J Wikipedia with Longer Sequence Length

The histogram raw data for Wikipedia with different maximum sequence length is provided in Listing 6 and visualized in Figure 9. We can see that with increasing maximum sequence length, long sequences become more and more rare and the resulting benefits from packing drastically increase. Keeping in mind that the BERT dataset generation process decreases the size of a maximum of 50% of the sequences, we can infer that having a different dataset generator that truncates any short sequence, would result in significant loss of data (> 25% for length 512).

Figure 9: Sequence length distributions for different sequence lengths in Wikipedia BERT pre-training dataset and according theoretical speed-up.

Due to the length distribution, it is not anymore sufficient to concatenate only 3 sequences to obtain perfect packing for maximum sequence length 1024 or 2048. Instead, around 6 and 12 sequences are required. This cannot be solved by NNLSHP anymore due to search space complexity but requires an online heuristics like SPFHP or the slightly better LPFHP, introduced in Section R that is based on Best-Fit and splitting counts in the histogram in contrast to the rather simple First-Fit descending. Figure 10 shows the achieved speed-ups with LPFHP depending on the maximum number of allowed sequences.

Figure 10: Speed-ups achieved by LPFHP for different maximum sequence length and maximum number of packed sequences.

1056 K Packing SQuAD 1.1

We tokenized SQuAD [25] for BERT [6] with maximum sequence length 384 and visualized the 1057 histogram over the sequence length (Figure 11). The distribution looks similar to the Wikipedia 1058 dataset but is slightly less skewed. However, the maximum sequence length only had an occurrence 1059 of 1.2% compared to 23.5%. Hence, the theoretical un-padding speedup is 2.232. In Table 5, we can 1060 see that SPFHP does not concatenate more than 3 samples and obtains 97.54% efficiency in contrast 1061 to a maximally used depth of 16 with 99.60% efficiency on Wikipedia, because of the less skewed 1062 distribution. Note that we have less than 90'000 samples. Hence, NNLSHP is less efficient because 1063 the rounding in the residuals has a much larger impact compared to more than 16 million sequences 1064 in the Wikipedia dataset. 1065

1066 L Packing GLUE

To explore a variety of datasets and emphasize that skewed distributions are common, we explored all 1067 datasets in the GLUE benchmark [31, 30] that came with training data. We loaded the datasets using 1068 the HuggingFace dataset loading API 47. For preprocessing, we followed the implementation in the 1069 HuggingFace transformers repository [32]³ and extracted the respective data processing snippets 1070 to obtain tokenized data with a maximum sequence length of 128. The histogram of the sequence 1071 length for each of the included datasets is displayed in Figure 12 and the packing results are given in 1072 Table 6 Each dataset benefits from packing. The lower the mean, the higher the packing factors are 1073 that can be reached but with a higher packing depth. 1074

1075 M Packing Audio Data (LibriSpeech)

In this section, we show that packing can benefit other domains than NLP like ASR. We use the LibiSpeech dataset [23] and preprocess it as described at a reference implementation.⁴ The resulting histograms for the subsampled audio sample lengths and respective text labels are provided in Figure [13]

Figure 13: LibriSpeech sequence length histograms of preprocessed audio data [top] as well as target text data [bottom].

It can be seen that the audio sequence length is dominated by long sequences with 38% of required padding to meet the max sequence length of 330. Thus the theoretical optimal speed-up of 1.6xcannot be reached. However, 80% efficiency are possible with any of the proposed packing algorithms to achieve 1.3x speed-up. This can be already achieved by combining up to 2 sequences. To achieve almost perfect packing efficiency, a sequence length around 457 and concatenating up to 8 sequences is required. Due to the quadratic increased computational load that usually comes with longer sequence length, increasing the sequence length is not practical.

In processing and packing the text data independently of the audio, 99.99% efficiency could be achieved with a speed-up of 2.24x.

⁴https://github.com/mlcommons/training/tree/master/rnn_speech_recognition/pytorch

1089 N Packing Paper Abstracts (PubMed)

This section analyses the length of abstracts to give an intuition about how different documents can be in length. Figure 14 depicts the length of abstracts in characters extracted from PubMed.⁵ If these abstracts were directly used as sequences, a character length of 1000 could result in 1.9xspeed-up from packing. The potential speed-ups for length 2000, 3000, 4000 would be 2x, 3x, and 4x, respectively. Note that, document clean-up procedures would usually eliminate documents that are too short or too long for data sanitizing purposes.

Figure 14: Abstract length distribution in PubMed.

1096 Note that for the processing in BlueBERT [45], paper titles and abstracts get separated into sequences, 1097 tokenized, and then combined with the BERT sequence combination approach for a maximum

¹⁰⁹⁸ sequence length of 128 tokens. Thus, it results in a different distribution.

¹¹⁰³ **Q** Note on changing the sequence length for optimal packing

An interesting aspect of packing is that the maximum sequence length for packing could be larger than the maximum sequence length in the underlying dataset that gets packed.

For the QM9 dataset, this means that by setting the maximum sequence length to 36 instead of 27 an optimal 1.6x speed-up can be easily achieved.

Note that the choice of maximum sequence length depends on the underlying machine learning algorithm. Due to the squared computational and memory complexity of self-attention in BERT and other transformers, the maximum sequence length is usually kept as small as possible for these models. So an increase for packing alone is not practical. For algorithms with linear complexity as for example Graph Neural Networks, implemented in PyG, larger maximum sequence length can be chosen to ensure, optimal packing is always possible.

1114 **R** Fine-tuned longest-pack-first histogram-packing

In the main paper, we focused on SPFHP due its simplicity. In this section, we analyse the effect of 1115 applying the "Best-Fit" algorithm [12]. Here, the longest pack that still fits the sequence is chosen 1116 instead of the shortest one. In contrast to SPFHP, we additionally consider splitting the histogram 1117 count, if it can fit multiple times. A simple example is sequence length 256, where we divide the 1118 respective histogram count by 2 to create the optimal pack with strategy [256, 256] instead of the 1119 strategy [256]. This latter strategy would be complemented by other sequences but would probably 1120 not result in an optimal packing. The implementation of this approach is much more complex than 1121 the SPFHP implementation. The code is provided in Listing 8 and the results in Table 7. 1122

pack.	# strat.	# packs	# tokens	# padding	efficiency	pack.
depth	used			tokens	(%)	factor

Table 7: Performance results of longest-pack-first histogram-packing for Wikipedia BERT pre-training with maximum sequence length 512.

We can see that longest-pack-first histogram-packing (LPFHP) uses a much higher packing depth when no limit is set (29 instead of 16). Splitting the histogram counts results in slightly higher numbers of used strategies compared to SPFHP where the number of used strategies is limited by the maximum sequence length. The best efficiency of LPFHP is 99.949% with packing factor of 2 which is slightly higher than the 99.75% (1.996 packing factor) for NNLSHP and 99.6% for SPFHP (1.993 packing factor). All algorithms are very close to the upper limit.

Note that for NNLSHP, we only fill up the unpacked samples with padding. Applying best-fit on the remains, similar results can be expected. Although the benefits of the improved algorithm are negligible, we share the concept and code below in case packing is applied to other data with a different distribution that would benefit more from it, or for applications where only perfectly packed sequences without padding are of interest.

1134 S Extended NNLS with padding token weighting

¹¹³⁵ In Section F.4.4, we defined the residual as

$$r = b - A \cdot round(x) \tag{21}$$

and discovered that a positive residual corresponds to sequences that we did not pack at all and should be avoided. Negative residuals correspond to padding and should be minimized. Due to this discrepancy, we decided to set small weights for very short sequences (that don't occur in the data). However, it was not possible to directly optimize the amount of padding. A negative residual component for length i, r_i , results in $|r_i| \cdot i$ padding tokens, however a positive residual actually results into $(512 - r_i) \cdot i$ padding tokens. This cannot be addressed by our weighting approach in

$$\min_{x \in \mathbb{R}^m} \| (wA) \cdot x - (wb) \|^2$$
s.t. $x \ge 0$
(22)

1142 Working within the NNLS approach, we can strictly enforce a non-positive residual r (before rounding 1143 to integer). To that end, we define a new auxiliary variable $\bar{r} \approx -(b - Ax)$ which is the negative of 1144 the residual, r. This will allow us to reformulate the objective $r \leq 0$ to the non-negative constraint: 1145 $\bar{r} \geq 0$.

$$\min_{x \in \mathbb{R}^m} \|(wA) \cdot x - (wb)\|^2 + \|\overline{w} \cdot A \cdot x - \overline{w} \cdot b - \overline{w} \cdot \overline{r}\|^2$$
s.t. $x \ge 0$
 $\overline{r} \ge 0$
(23)

This will enforce $\overline{r} = Ax - b \ge 0$ due to the large weight, $\overline{w} := 10^6$, and no upper limits on \overline{r} . Now, we can set $w_i := i$ to optimize for the padding tokens. Due to the use of the squared error, we would however optimize the squared sum of padding tokens instead of the preferred sum of padding tokens. To accomplish the latter, we would have to replace the L2-norm problem by an L1-norm problem which would be too complex to solve. Note that due to rounding, the unwanted positive residuals r($\overline{r} < 0$) might still occur. This could be avoided by rounding up x instead of normal rounding of x. To put the new formulation into a solver, we replace

$$b \text{ by } \begin{pmatrix} b \\ b \end{pmatrix}, x \text{ by } \begin{pmatrix} x \\ \overline{r} \end{pmatrix}, w \text{ by } \begin{pmatrix} w \\ \overline{w} \end{pmatrix}, \text{ and } A \text{ by } \begin{pmatrix} A & 0_m \\ A & -D_m \end{pmatrix},$$
 (24)

where 0_m is an $m \times m$ matrix with m being the maximum sequence length, 512, and D_m is a unit matrix of the same dimensions as 0_m . Since, we are already close to optimum especially on the Wikipedia dataset, the results are only a little bit better. The processing time however increases from 30 to 415 seconds without considering the increased time for constructing the processing matrix. Since the slightly improved algorithm might be nevertheless relevant for other applications, we share it in Listing 9.
