1 A Preliminaries

2 **Markov Decision Process (MDP).** A standard MDP can be represented as a tuple: $(\mathcal{S}, \mathcal{A}, \mathcal{P}, \mathcal{R}, \gamma, T)$,
3 where \mathcal{S} denotes the state set, \mathcal{A} denotes an action set, \mathcal{P} is the transition function: $\mathcal{S} \times \mathcal{A} \times \mathcal{S} \rightarrow [0, 1]$
4 and \mathcal{R} is the reward function: $\mathcal{S} \times \mathcal{A} \rightarrow \mathbb{R}$. $\gamma \in [0, 1)$ is a discount factor and T is the decision
5 horizon. The target of the agent is to optimize its policy to maximize the expected discounted
6 cumulative reward.

7 **Frameskip.** Frame-skipping may be viewed as an instance of (partial) open-loop control, under which
8 a predetermined sequence of (possibly different) actions is executed without heed to intermediate
9 states. Aiming to minimize sensing, ? proposes a framework for incorporating variable-length
10 open-loop action sequences in regular (closed-loop) control. The primary challenge in general
11 open-loop control is that the number of action sequences of some given length d is exponential in d .
12 Consequently, the main focus in the area is on policies to prune corresponding data structures (?).
13 Since action repetition restricts itself to a set of actions with size linear in d , it allows for d itself to be
14 set much higher in practice. With frame-skipping, the agent is only allowed to sense every d state: that
15 is, if the agent has sensed a state s_t at time step $t \geq 0$, it is oblivious to states $s_{t+1}, s_{t+2}, \dots, s_{t+d-1}$,
16 and next only observes s_{t+d} .

17 **Variational Auto-encoder.** The variational auto-encoder (VAE) is a directed graphical model with
18 certain types of latent variables, such as Gaussian latent variables. A generative process of the
19 VAE is as follows: a set of latent variable z is generated from the prior distribution $p_\theta(z)$ and
20 the data x is generated by the generative distribution $p_\theta(x|z)$ conditioned on $z : z \sim p_\theta(z), x \sim$
21 $p_\theta(x|z)$. In general, parameter estimation of directed graphical models is often challenging due to
22 intractable posterior inference. However, the parameters of the VAE can be estimated efficiently in
23 the stochastic gradient variational Bayes (SGVB) framework, where the variational lower bound of
24 the log-likelihood is used as a surrogate objective function. In this framework, a proposal distribution
25 $q_\theta(x|z)$, which is also known as a “recognition” model, is introduced to approximate the true posterior
26 $p_\theta(x|z)$. The multilayer perceptrons (MLPs) are used to model the recognition and the generation
27 models. Assuming Gaussian latent variables, the first term of Equation A can be marginalized,
28 while the second term is not. Instead, the second term can be approximated by drawing samples
29 $z^{(l)} (l = 1, \dots, L)$ by the recognition distribution $q_\theta(x|z)$, and the empirical objective of the VAE with
30 Gaussian latent variables is written as follows:

$$L_{VAE}(\phi, \psi) = \frac{1}{L} \sum_{\theta} (x|z^{(l)}) - KL(q_\phi(z|x)||N(0, I)) \quad (1)$$

Table 1: Network Structures for DRL Methods

32 B Experimental Details

33 B.1 NETWORK STRUCTURE

34 Our codes are implemented with Python 3.7.9 and Torch 1.7.1. All experiments were run on a single
 35 NVIDIA GeForce GTX 2080Ti GPU. Each single training trial ranges from 4 hours to 17 hours,
 36 depending on the algorithms and environments. We will open source code in the near future.

37 Our TD3 is implemented with reference to github.com/sfujim/TD3 (TD3 source-code).
 38 DDPG and PPO are implemented with reference to [https://github.com/sweetice/
 39 Deep-reinforcement-learning-with-pytorch](https://github.com/sweetice/deep-reinforcement-learning-with-pytorch). For a fair comparison, all the baseline meth-
 40 ods have the same network structure (except for the specific components of each algorithm) as our
 MARS-TD3 implementation. As shown in Tab.1, we use a two-layer feed-forward neural network of

Model Component	layer	dimension
Conditional Encoder Network	Fully Connected (encoding)	$(\mathbb{R}^x, 256)$
	Fully Connected (condition)	(state dim + v dim, 256)
	Element-wise Product	ReLU (encoding), ReLU(condition)
	Fully Connected	(256, 256)
	Activation	ReLU
	Fully Connected (mean)	(256, latent space dim)
	Activation	None
	Fully Connected (log std)	(256, latent space dim)
	Activation	None
	Conditional Decoder, Prediction Network	Fully Connected (latent)
Fully Connected (condition)		(state dim + v dim, 256)
Element-wise Product		ReLU (encoding), ReLU(condition)
Fully Connected		(256, 256)
Activation		ReLU
Fully Connected (v)		(256, action dynamic transition)
Activation		None
Fully Connected (reconstruction)		(256, multi-step action dim)
Activation		None
Fully Connected		(256, 256)
Activation	ReLU	
Fully Connected (prediction)	(256, state dim)	
Activation	None	

Table 2: Network structures for the Multi-step action representation (MARS).

41 256 and 256 hidden units with ReLU activation (except for the output layer) for the actor network
 42 for all algorithms. For DDPG the critic denotes the Q-network. For PPO, the critic denotes the
 43 V-network. All algorithms (TD3, DDPG, PPO) output two heads at the last layer of the actor network,
 44 one for latent action and another for dynamic transition potential.
 45

46 The structure of MARS is shown in Tab.2. We use element-wise product operation (?) and cascaded
 47 head structure (?) to our model.

48 B.2 Hyperparameter

49 For all experiments, we use the raw state and reward from the environment, and no normalization or
 50 scaling is used. No regularization is used for the actor and the critic in all algorithms. An exploration
 51 noise sampled from $N(0, 0.1)$ (?) is added to all baseline methods when selecting an action. The
 52 discounted factor is 0.99 and we use Adam Optimizer (?) for all algorithms. Tab.3 shows the common
 53 hyperparameters of algorithms used in all our experiments.

Hyperparameter	Frameskip-TD3	Multistep-TD3	MARS-PPO	MARS-TD3	MARS-DDPG
Actor Learning Rate	$1e^{-4}$	$1e^{-4}$	$1e^{-4}$	$1e^{-4}$	$1e^{-4}$
Critic Learning Rate	$1e^{-3}$	$1e^{-3}$	$1e^{-3}$	$3e^{-4}$	$3e^{-4}$
Representation Model Learning Rate	None	None	None	$1e^{-4}$	$5e^{-3}$
Discount Factor	0.99	0.99	0.99	0.99	0.99
Batch Size	128	128	128	128	128
Buffer Size	$1e5$	$1e5$	$1e5$	$1e5$	$1e5$

Table 3: A comparison of common hyperparameter choices of algorithms. We use ‘None’ to denote the ‘not applicable’ situation.

54 B.3 Additional Implementation Details

55 For PPO, the actor network and the critic network are updated every 2 and 10 episode respectively
 56 for all environments. The clip range of the PPO algorithm is set to 0.2 and we use GAE (?) for a
 57 stable policy gradient. For DDPG, the actor network and the critic network is updated at every 1
 58 environment step. For TD3, the critic network is updated every 1 environment step and the actor
 59 network is updated every 2 environment steps.

60 The default latent action dim is 8, we set the KL weight in representation loss L_{MARS} as 0.5.
 61 Environment dynamic prediction loss weight β is 5 (default).

62 C Additional experiment

63 C.1 Performance of model-based reinforcement learning algorithms on Intermittent-MDP 64 tasks.

Methods	Ant (fixed-Intermittent)	Hopper (fixed-Intermittent)	Ant (random-Intermittent)	Hopper (random-Intermittent)
TD-MPC	1795.4 ± 375.6	1795.4 ± 214.8	1447.2 ± 694.8	1073.6 ± 157.1
Dreamer-v2	1648.2 ± 417.5	788.1 ± 116.4	1064.7 ± 694.8	974.7 ± 201.8
TD3-multistep	2673.6 ± 316.8	1359.7 ± 258.3	2795.4 ± 264.1	1211.6 ± 169.5
MARS-TD3	2572.9 ± 248.1	3762.7 ± 371.4	3105.7 ± 412.6	2647.9 ± 204.8

Table 4: Comparison between MBRL and MFRL in intermittent control tasks, average of 3 runs.

65 The results in Table 4 show that the model-based reinforcement learning approach is significantly
 66 lower than our approach in all four scenarios, and even slightly worse than using TD3 for direct
 67 multi-step decision making. We analyze that this is because the errors caused by the mismatch
 68 (sub-optimal) of the dynamic model will accumulate due to multi-step decision-making, resulting in
 69 sub-optimal policy. Unfortunately, the training of dynamic models is data hungry (high cost), that
 70 is, a large amount of high-quality expert data is required to ensure the accuracy of the model shop,
 71 which is difficult to obtain, especially in real-world scenarios.

72 C.2 Validation of the combination of MARS and online methods

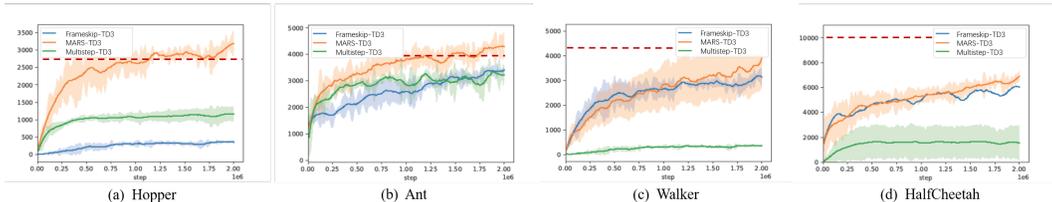

Figure 1: The performance of the methods on four simulated tasks. The curve and shade denote the mean and a standard deviation over 5 runs.

73 We use the mainstream online reinforcement learning algorithm TD3 in combination with MARS and
 74 compare it with the baseline mentioned in Sec.?? in four tasks. We set the interval to 10 time steps,
 75 requiring the policy to generate an effective action sequence $a_{t:t+9}$ based on the received state s_t .

76 For all tasks, we set the dimension of z_t to 12 and the scaling parameter β to 4. We set the warm-up
 77 (stage 1) step to 300000 and 100000 for the Mujoco tasks and the navigation task respectively. The
 78 results in Figure 1 show that MARS-TD3 outperforms the other baselines in all fixed Intermittent-
 79 MDP tasks and achieve comparable performance with perfect-TD3 in most tasks. **This further**
 80 **proves that MARS can effectively improve the effectiveness of Online DRL on fixed Intermi**
 81 **tasks.**

82 C.3 Generalization of MARS

83 We test MARS with popular RL methods on three tasks: Hopper, Walker, and hardMaze. To make
 84 the experiment fair, we used the same parameters for all methods and implemented them based on
 85 public code. We use each RL algorithm to train on three tasks under the ideal setting and compare
 86 them with their corresponding improvement methods. To show the optimal score after the algorithm
 87 convergence, we train all the algorithm’s 2000000 time steps. The results in Tab.5 show that all
 88 methods can learn effective policies with the help of MARS and perform similarly to their ideal
 89 settings. The differences in scores are mainly due to the variation in performance of the RL algorithms.
 90 In summary, MARS can be combined with different methods to provide a reliable action space for
 solving Intermittent-MDP as normal MDP with RL.

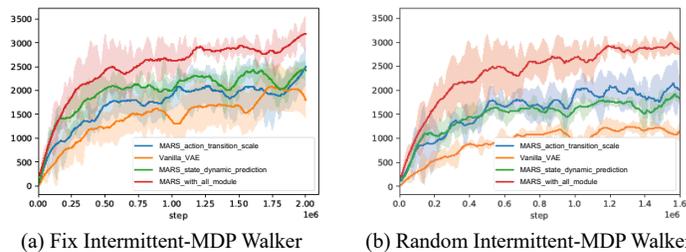

Benchmarks	MARS-PPO	MARS-DDPG	MARS-TD3
Maze hard	256 0.7 \uparrow	243 2.5 \uparrow	311 16.3 \uparrow
Hopper	2851.4 13.5 \downarrow	1815.6 184.3 \uparrow	3384 53.1 \uparrow
Walker	3831.2 285.1 \downarrow	1032.7 201.9 \downarrow	4821.6 427.6 \uparrow

Table 5: The parameters of all methods are optimized by grid search. The results of applying MARS to popular RL algorithms on three random interaction interval tasks. The maximum interaction interval is set to 8. Each data in the table is in the following format: MARS-RL score | the score difference compared to the perfect dense interaction baseline. \downarrow denotes the score of MARS lower than the dense interaction baseline. \uparrow denotes the score of MARS is higher. All scores are averaged over 5 runs.

91

92 C.4 Details of Ablation study

93 We conducted two exper-
 94 iments to show how well
 95 the two mechanisms of
 96 MARS work together. Al-
 97 though the results of ran-
 98 domized Intermittent-MDP
 99 and fixed Intermittent-MDP
 100 are slightly different, the
 101 same conclusion can be de-
 102 rived: The green curves in
 103 Figure 2 demonstrate that
 104 the representation model
 105 with increased action transition
 106 scale is much better than the
 107 original VAE. This means that
 108 dynamic transition potential
 109 can create a latent action space
 110 by explicitly modeling the
 dependence between multi-step
 actions. The blue curves also
 show that VAE with state
 dynamic prediction is better
 than the original VAE because
 it can represent action se-
 quences that have similar
 environmental effects at close
 locations. Finally, the red
 curves show that the two
 mechanisms work well to-
 gether in MARS, and combin-
 ing them improves representa-
 tion ability.

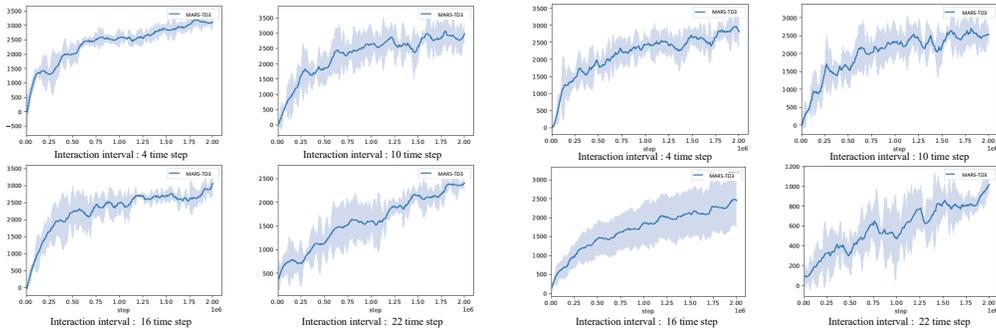

102

103 Figure 2: Details of ablation study. The curve and shade denote the mean and
 104 a standard deviation over 5 runs.
 105 with increased action transition scale is much better than the original VAE. This means that dynamic
 106 transition potential can create a latent action space by explicitly modeling the dependence
 107 between multi-step actions. The blue curves also show that VAE with state dynamic prediction is
 108 better than the original VAE because it can represent action sequences that have similar environmental
 109 effects at close locations. Finally, the red curves show that the two mechanisms work well together in
 110 MARS, and combining them improves representation ability.

111 C.5 Validity verification of multi-style interaction intervals

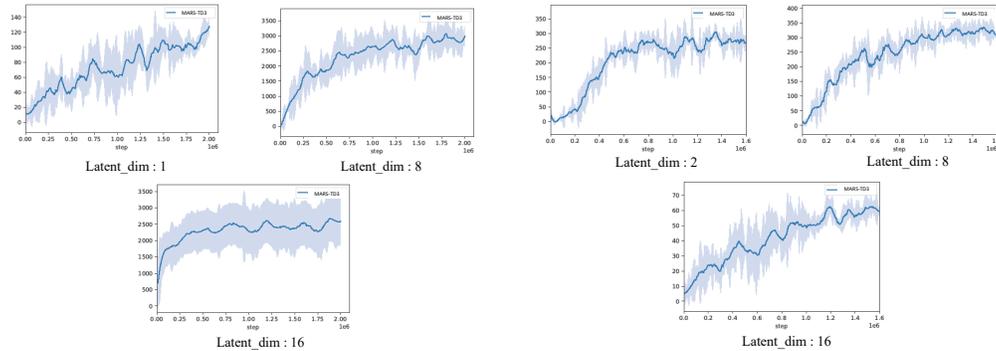

112 To further demonstrate the effectiveness of MARS in diverse intermittent control scenarios. For
 113 fixed interaction control tasks, we uniformly set the forbidden interaction duration and conducted
 114 four experiments on Hopper. The results in Figure 3(a) show that MARS can solve most tasks
 115 effectively and still guarantee good scores at long intervals, but the effectiveness of MARS decreases
 116 significantly when the interval is too long (which is not common in real-world scenarios). We believe

(a) Fixed Intermittent-MDP scenarios

(b) Random Intermittent-MDP scenarios

Figure 3: The curve and shade denote the mean and a standard deviation over 5 runs.

(a) Results on Hopper

(b) Results on MAZE

Figure 4: The curve and shade denote the mean and a standard deviation over 5 runs.

117 that this is because VAE is unable to effectively characterize excessively long sequences, leading to
 118 the failure of multi-step action space modeling.

119 In addition, to observe the sensitivity of MARS to interaction intervals on random Intermittent-MDP
 120 tasks, we uniformly set the forbidden interaction duration and conducted four experiments on Hopper.
 121 The results in Figure 3(b) show that in random Intermittent-MDP scenarios, MARS performs well
 122 in both short and medium-interval scenarios. However, convergence changes slowly in the very
 123 long interval scenario, and the score is only half that of the medium interval task. Because MARS’s
 124 representational capabilities are not perfect for modeling long action sequences for extremely long-
 125 spaced tasks (even if this setting rarely occurs in real-world scenarios). Therefore, in the future, we
 126 hope to find more suitable representation models to overcome this problem.

127 C.6 The influence of Latent action space dimension on algorithm effect

128 The representation space dimension of VAE is an important hyperparameter. If the latent space
 129 dimension is too low, a large amount of original data information will be lost, resulting in invalid
 130 representation space. On the contrary, when the latent space dimension is too large, the calculation
 131 amount of the model will be increased. To verify the sensitivity of MARS to latent space dimensions,
 132 we test it on two tasks with different original action dimensions. We set up four sets of latent
 133 space dimensions for fixed Intermittent-MDP Hopper (interaction interval time step: 8, original
 134 action dimension: 3, so the action sequence dimension to be modeled is 24). The learning curve in
 135 Figure 4(a) shows that for raw data of such high dimensions, when the latent space dimension is set

136 too low, the latent space information will be lost, resulting in the convergence failure of reinforcement
 137 learning policies. On the contrary, too high a latent space dimension increases the complexity of
 138 reinforcement learning policy exploration.

139 In addition, we set up four comparison experiments on the 2dmaze task with a lower dimension of
 140 the original action sequence (interaction interval time step: 4, original action dimension: 2, so the
 141 action sequence dimension to be modeled is 8). The experimental results in Figure 4(b) show that the
 142 suboptimal policy can be learned when the latent space dimension is low, because the original data
 143 dimension is low. So the low-dimensional latent space loses less information. The score increases as
 144 the latent space dimension increases. However, when the latent space dimension is too high, the score
 145 will drop significantly, which is because of the exploration difficulties brought by high-dimensional
 146 latent space.

147 C.7 The influence of environment steps of warmup stage

148 In this section, we conduct some additional experimental results for a further study of MARS from
 149 different perspectives: We provide the exact number of samples used in the warm-up stage (i.e.,
 150 stage 1 in Algorithm ?? in each environment in Tab.6. The number of warm-up environment steps
 151 is about 5% ~ 10% of the total environment steps in our original experiments. Moreover, we also
 152 conducted some experiments to further reduce the number of samples used in the warm-up stage (at
 153 most 80% off). See the colored results in Tab.6. MARS can achieve comparable performance with
 154 < 3% samples of the total environment steps.

155 Conclusion: The number of warm-up environment steps is about 5% ~ 10% of the total environment
 156 steps in our original experiments. The number of warmup environment steps can be further reduced
 157 by at most 80% off (thus leading to < 3% of the total environment steps) while the comparable
 performance of our algorithm remains.

Environment	Warm-up steps (original)	Warm-up steps (new)	Total Env. Steps
Hopper	400000(0.08 3219.1)	100000(0.02 3086.4)	5000000
Ant	400000(0.08 4305.7)	100000(0.02 4025.6)	5000000
Walker	400000(0.08 4961.3)	100000(0.02 4792.6)	5000000
HalfCheetah	400000(0.08 6593.2)	100000(0.02 6071.2)	5000000
2dmaze-medium	100000(0.083 127.8)	30000(0.025 118.5)	1200000
2dmaze-hard	100000(0.083 327.6)	35000(0.0292 296.1)	1200000

Table 6: The exact number of samples used in warm-up stage training in different environments. The column of ‘original’ denotes what is done in our experiments; the column of ‘new’ denotes additional experiments we conduct with fewer warm-up samples (and proportionally fewer warm-up training). For each entry $x(y|z)$, x is the number of samples (environment steps), y denotes the percentage number of $\frac{\text{warm-up environment steps}}{\text{number of total environment steps during the training process}}$, and z denotes the corresponding performance of MARS-TD3.

158
