

Supplementary Materials: Reginal Attention For Shadow Removal

Anonymous Authors

1 MORE VISUAL RESULTS

In this section, we bring more visual results and comparisons with state-of-the-art methods on the ISTD+ dataset [7] (Please see Fig. 1, Fig. 2) and SRD dataset [8] (Please see Fig. 3).

2 DISCUSSION ON LOSSES

The loss function of our model turns out to be:

$$\mathcal{L} = \alpha_1 \mathcal{L}_{per} + \alpha_2 \mathcal{L}_{cont}, \quad (1)$$

where \mathcal{L}_{cont} is Charbonnier Loss [6], and \mathcal{L}_{per} is VGG perceptual loss. To verify the necessity of the loss terms, we conducted ablation studies on the ISTD+ dataset [7] by removing \mathcal{L}_{vgg} term. As depicted in Tab. 1, the VGG perceptual loss boosts the performance by 0.38 dB PSNR in shadow region and 0.21 dB PSNR in all image.

3 VISUALIZATION OF REGIONAL ATTENTION

To validate whether our proposed regional attention mechanism truly enables shadow areas to interact with their adjacent non-shadow areas, we selected several points on the image and visualized their attention weight allocation. As shown in Fig. 4, we can see that in completely illuminated areas or shadow areas, the attention weights of these points are relatively low and even, while points in shadows have a much larger attention weight when the attention area can encompass the surrounding non-shadow areas. Moreover, the second case and the third case of Fig. 4 show that not all non-shadowed regions are assigned high attention weights. Rather, non-shadowed region information which is similar to the selected points receives higher weights. This further illustrates that our regional attention mechanism enables each area in the shadow to select the surrounding non-shadowed region information that is helpful for its reconstruction.

4 SELECTIVE SHADOW REMOVAL

We also tested our model with human interaction. As shown in Fig. 5, with the help of Segment Anything [5], the model permits the user to select the areas requiring shadow removal by simple straightforward clicks. It then generates high-quality shadow removal results for the specified shadow mask. This capability enables our model to respond effectively to selective shadow removal requirements.

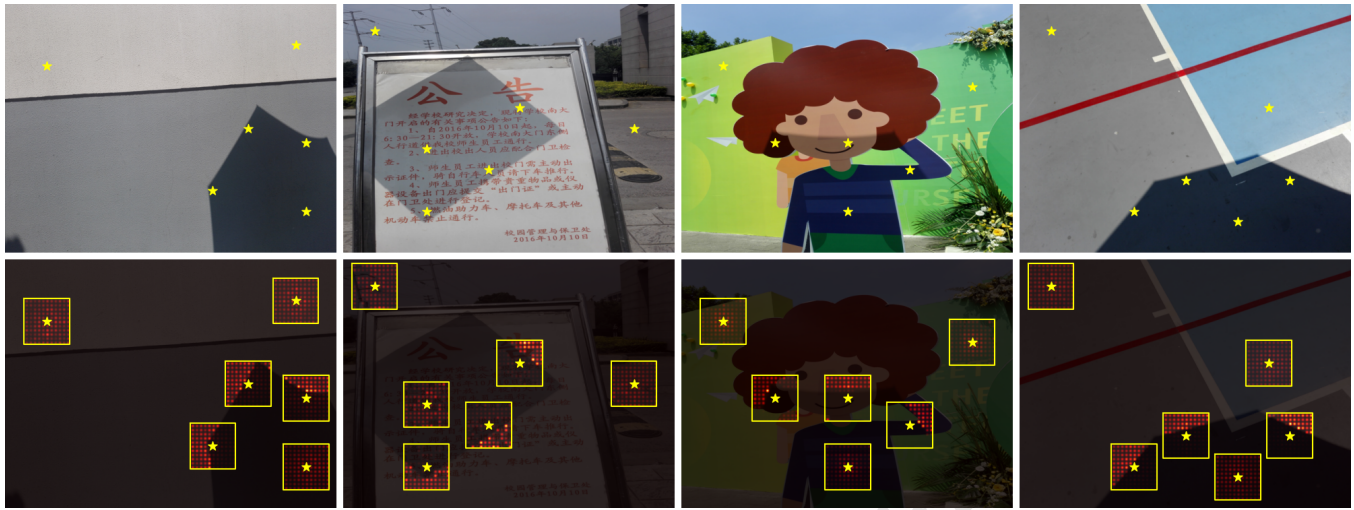

Figure 4: Visualization of our regional attention. The original image is on the first row, and the star marks the selected points. The heatmaps indicate the regional attention weight of the marked tokens. Brighter colors indicate a larger attention score.

(a) Input

(b) Shadow Area Selection

(c) Mask

(d) Output

Figure 5: Selective shadow removal. In the second column of images, the green dots represent the areas we want to select, while the red dots represent the areas we wish to exclude from the selection. By selecting the shadow areas to be removed, our model can flexibly generate corresponding high-quality shadow removal results.
