## 1 DENOISING DIFFUSION MODEL

Given a dataset  $D = \{x_i\}_{i=1}^N$ , the diffusion model learns a mapping from the standard normal distribution  $\mathcal{N}(0, I)$  to the distribution  $p(x)$  to which  $D$  belongs. As a result, we can generate a random vector  $\epsilon \sim \mathcal{N}(0, I)$  and feed it into the diffusion model to obtain a corresponding  $x$ , which will be a sample from the distribution  $p(x)$ .

In the training phase, the diffusion model is divided into a forward process and a reverse process. The forward process is a Markov process that adds noise to samples  $x_0$  in the dataset:

$$x_t = \sqrt{1 - \beta_t}x_{t-1} + \sqrt{\beta_t}\epsilon \quad (1)$$

where  $\beta_t$  represents a sequence of hyperparameters that is manually specified, and  $\epsilon$  is a random noise vector sampled from the standard normal distribution  $\mathcal{N}(0, I)$ . We can write Equation 1 in the form of a probability distribution:

$$q(x_t|x_{t-1}) = \mathcal{N}(x_t|\sqrt{1 - \beta_t}x_{t-1}, \beta_t I) \quad (2)$$

After performing the above forward process  $T$  times, we obtain  $x_T$ , and by setting  $\beta_t$  appropriately, we can make  $x_T$  approximately follow the distribution  $\mathcal{N}(0, I)$ . In addition, due to the characteristics of the Markov process, we can simplify the forward process into one step:

$$x_t = \sqrt{\bar{\alpha}_t}x_0 + \sqrt{1 - \bar{\alpha}_t}\epsilon \quad (3)$$

where  $\bar{\alpha}_t = \prod_{s=0}^t \alpha_s$  and  $\alpha_t = 1 - \beta_t$ . Due to the reparameterization trick,  $\epsilon$  still obeys  $\mathcal{N}(0, I)$ . Therefore, we can write Equation 3 in the form of a probability distribution:

$$q(x_t|x_0) = \mathcal{N}(x_t|\sqrt{\bar{\alpha}_t}x_0, (1 - \bar{\alpha}_t)I) \quad (4)$$

According to Bayes rule, we can obtain the probability distribution expression for the reverse process:

$$q(x_{t-1}|x_t) = \frac{q(x_t|x_{t-1})q(x_{t-1})}{q(x_t)} \quad (5)$$

Since we do not know the exact form of  $q(x_0)$ , we cannot solve the integral for computing  $q(x_t)$ :  $q(x_t) = \int q(x_t|x_0)q(x_0)dx_0$ . Instead, we use the empirical distribution to approximate  $q(x_0)$ , by adding  $x_0$  as a condition to the probability distribution. Therefore, Equation 5 can be written as:

$$q(x_{t-1}|x_t, x_0) = \frac{q(x_t|x_{t-1}, x_0)q(x_{t-1}|x_0)}{q(x_t|x_0)} \quad (6)$$

Obviously Equation 6 can be calculated from Equation 2 and Equation 4:

$$\begin{aligned} & q(x_{t-1}|x_t, x_0) \\ &= \mathcal{N}\left(x_{t-1} \middle| \frac{\sqrt{\bar{\alpha}_{t-1}}\beta_t}{1 - \bar{\alpha}_t}x_0 + \frac{(1 - \bar{\alpha}_{t-1})\sqrt{1 - \beta_t}}{1 - \bar{\alpha}_t}x_t, \frac{1 - \bar{\alpha}_{t-1}}{1 - \bar{\alpha}_t}\beta_t I\right) \end{aligned} \quad (7)$$

We cannot get  $x_0$  directly during generation, so we use a neural network  $s_\theta(x_t, t)$  to fit  $x_0$ :

$$\mathcal{L} = \|s_\theta(x_t, t) - x_0\|_2^2 \quad (8)$$

In the sampling phase, we use the trained neural network  $s_\theta(x_t, t)$  to replace  $x_0$  in Equation 6, thus obtaining the reverse process in the sampling step:

$$x_{t-1} = \frac{1}{\sqrt{\bar{\alpha}_t}}\left(x_t - \frac{\beta_t}{\sqrt{1 - \bar{\alpha}_t}}s_\theta(x_t, t)\right) + \frac{1 - \bar{\alpha}_{t-1}}{1 - \bar{\alpha}_t}\beta_t\epsilon \quad (9)$$

The reverse process is iterated  $T$  times, and the final  $x_0$  is the generated output of the model. For a detailed understanding of diffusion models, please refer to reference [1, 3–11].

## 2 EXPERIMENT IMPLEMENTATION DETAILS

In all experiments conducted in this paper, we use the unified pre-trained text-to-image model StableDiffusion 2.0<sup>1</sup> for InstantAS and all compared sampling methods. In the comparison experiment of sampling speed, we use the DDIM method with a fixed step size of 50 for all models. For the sake of fairness, we removed the acceleration packages in the code of some models, including xformers and accelerate, etc., so that all models can be compared under the same conditions.

## 3 REGIONAL CONTROL GENERATION COMPARISON

In this section, we demonstrate the region control generation capabilities of InstantAS and MultiDiffusion[2], as shown in Figure 1. The mask-based generation region limitation method used by MultiDiffusion employs masks to segment the latent representation of an image into different semantic regions, and applies different prompts to these regions separately. In contrast, InstantAS aligns semantic information to different regions in cross-attention through masks. Compared to MultiDiffusion, the target region shape control of MultiDiffusion is more refined. However, since InstantAS performs alignment after modification in the deeper feature cross-attention, the boundaries it affects cannot be represented very precisely. Nevertheless, InstantAS demonstrates significantly better fusion effects between regions than MultiDiffusion, resulting in more consistent and natural-looking generated images overall.

## 4 FAILURE CASES AND DISCUSSION

Experimental results show that compared to previous work, our method has significant advantages in terms of generation quality and sampling speed. However, our method still has some shortcomings. First, because larger-sized images exceed the training resolution of the diffusion model, it is difficult to find their latent representations in the latent space of the diffusion model. As a result, the generated images struggle to account for information that is far apart in the image, losing some global structure. This is specifically manifested in prompts with a single target or larger entities, where the method cannot accurately restore the content. Secondly, when the content described by the text is difficult to be compatible with the specified target image size, sometimes the content described by

<sup>1</sup><https://huggingface.co/stabilityai/stable-diffusion-2-base>

the text will be stacked in the image. Some failure cases are shown in Figure 2.

According to the manifold distribution hypothesis, for a fixed prompt, the latent feature distribution of its corresponding image data is located near a low-dimensional manifold within the high-dimensional space represented by a fixed-size image training set. However, for images of any size larger than this fixed size, they exist in a higher dimensional space. Therefore, how to utilize this low-dimensional manifold to search for embedding representations in the higher dimensional space, thereby obtaining images with consistency in the latent space, is the direction of our future research.

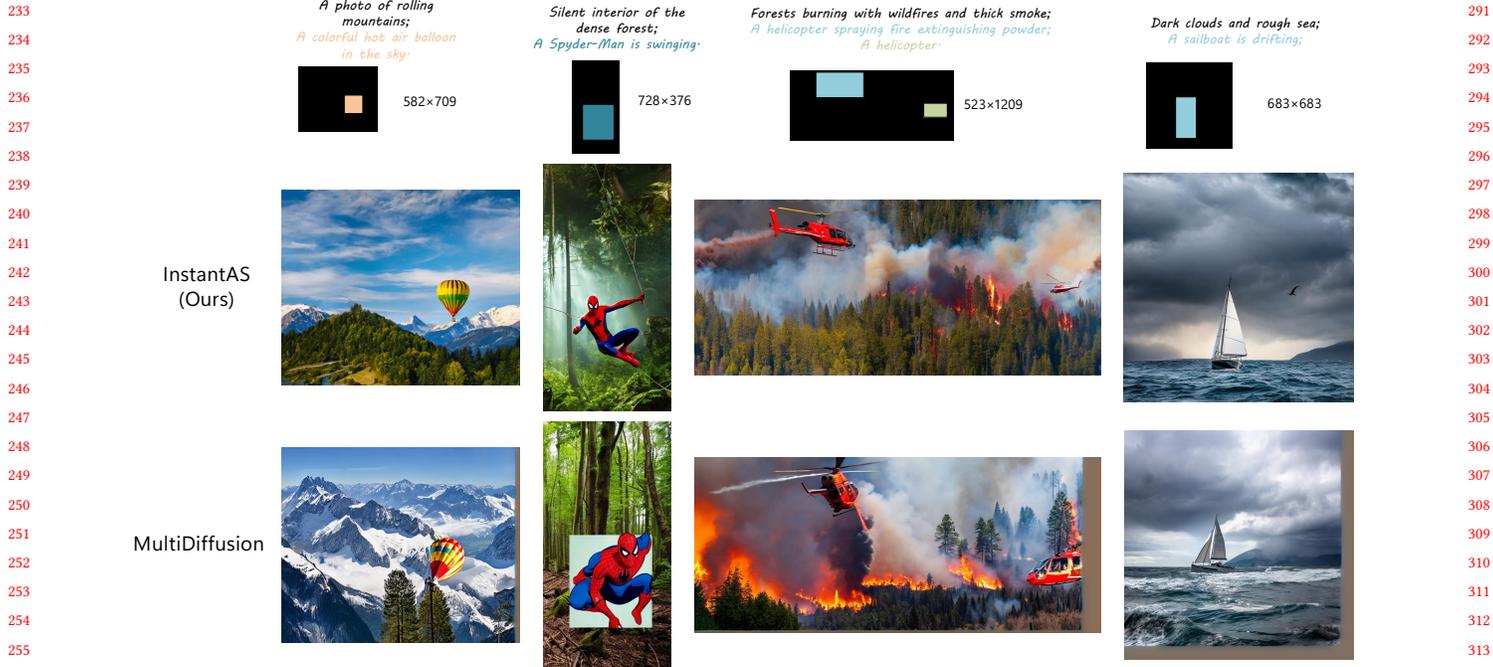

Figure 1: Comparison results of regional information control generation between InstantAS and MultiDiffusion. Our proposed InstantAS method has a more natural fusion of foreground and background, and does not appear contentless boundaries.

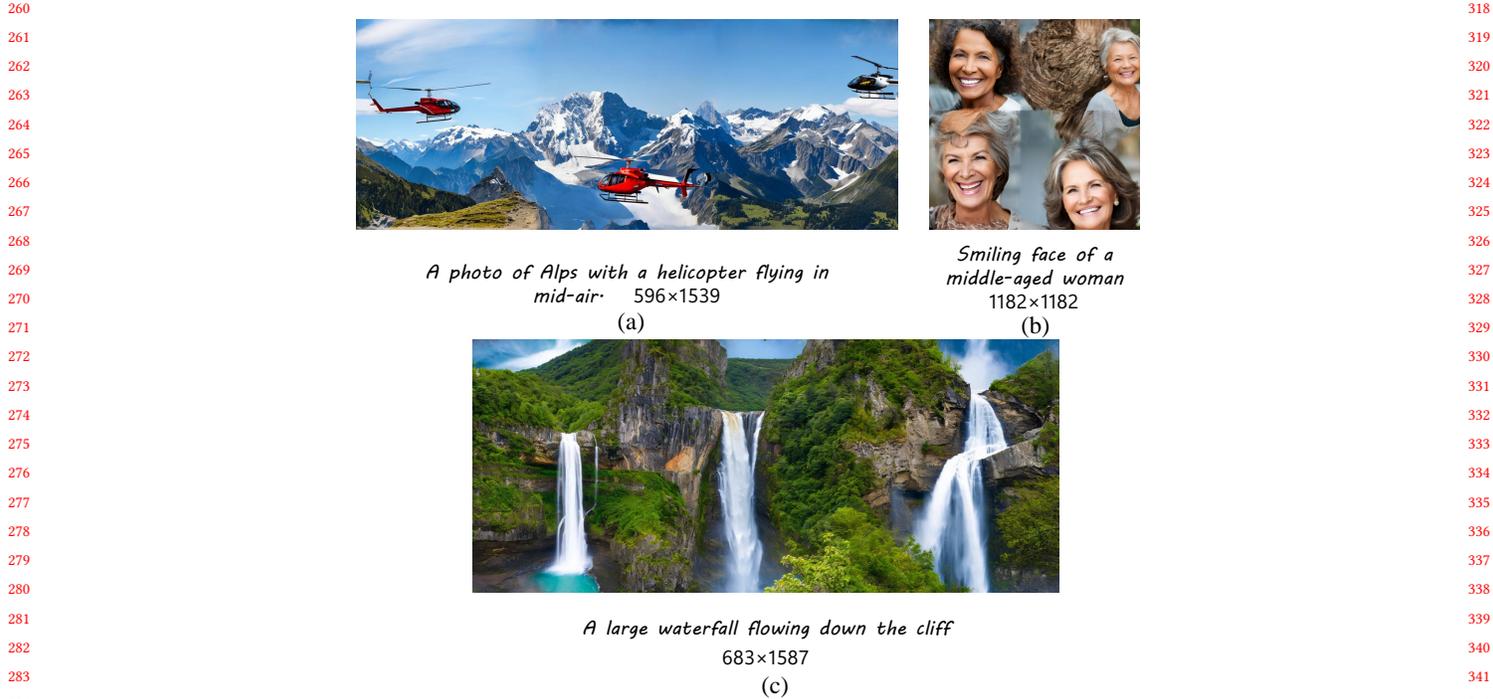

Figure 2: Some failure cases. (a) (b) When the described content includes specific quantities or entities with complete structures that occupy most of the image area, repetition of elements often occurs. (c) When the description content is incompatible with the image size, for example, when it is required to generate a waterfall from top to bottom in a horizontally long image, the generated results will often have content stacking.
