

490 **A Supplemental Material**

491 This supplementary material is organized as follows: Section A.1 provides more details about  
 492 Semantics-Layout Variation AutoEncoder; Section A.2 introduces the Stable Diffusion and its  
 493 attention mechanism; Section A.3 describes the implementation of the Multi-Layer Sampler in detail;  
 494 Section A.4 covers more ablation studies; Section A.5 presents more qualitative results, including  
 495 comparison visualization and graph manipulation; Section A.6 discusses the limitations of this study.  
 496 Section A.7 delves into the broader societal impacts of this work. The core script is zipped and  
 497 attached to the supplementary material.

498 **A.1 Semantics-Layout Variation AutoEncoder**

499 Recall that we apply the triplet-GCN-based CVAE architecture in Section 3.1. Each triplet-GCN layer  
 500 in the encoder and decoder takes the node and edge embeddings. Specifically, the  $GCN_l$  mentioned  
 501 in the paper uses two cascading MLPs  $\{\text{mlp}_1, \text{mlp}_2\}$  to deal with node and edge embeddings:

$$(\psi_i^l, \phi_{ij}^{l+1}, \psi_j^l) = \text{mlp}_1(\phi_i^l, \phi_{ij}^l, \phi_j^l), l \in \{0, \dots, L-1\}, \quad (12)$$

$$\phi_i^{l+1} = \psi_i^l + \text{mlp}_2(\text{avg}(\psi_j^l \mid j \in \mathcal{N}_{\mathcal{E}}(o_i))), \quad (13)$$

502 where  $l$  denotes the layer index of encoder or decoder,  $\mathcal{N}_{\mathcal{E}}$  denotes the neighbor index set for each  
 503 node,  $\text{avg}$  denotes the average pooling operation,  $\phi$  and  $\psi$  denote intermediate features. Hence,  $\text{mlp}_1$   
 504 conducts message passing among interconnected nodes and updates the edge features, while  $\text{mlp}_2$   
 505 aggregates features from all neighboring nodes and updates its features. For graph union encoder,  
 506 we let  $(\phi_i^0, \phi_{ij}^0, \phi_j^0) = (\mathcal{O}_i, \mathcal{E}_{ij}, \mathcal{O}_j)$ . The last embedding  $\phi_i^L$  is parameterized to the Gaussian  
 507 distribution  $Z \sim \mathcal{N}(\mu, \sigma)$ , where  $\mu, \sigma \in \mathbb{R}^{D_z}$  output by two additional MLPs and  $D_z$  denotes the  
 508 dimensional of latent space for node embedding.

509 **A.2 Diffusion with Compositional Masked Attention**

510 **Stable Diffusion** [20] is one of most popular text-to-image model. As described in Section 2.1,  
 511 Stable Diffusion uses a U-Net  $\epsilon_{\theta}$  composed of convolution and transformer to estimate noise. The  
 512 transformer includes two attention mechanisms, namely Cross-Attention, and Self-Attention.

513 **Cross-Attention Layer.** Text prompts are mapped to sequence embeddings by CLIP text encoder  
 514 and integrated into UNet via Cross-Attention to guide the de-noising trajectory:

$$\text{Attention}(Q_{\text{visual}}, K_{\text{text}}, V_{\text{text}}) = \text{softmax}\left(\frac{Q_{\text{visual}}K_{\text{text}}^T}{\sqrt{d}}\right) \cdot V_{\text{text}} \quad (14)$$

515 where  $Q_{\text{visual}}$  denotes the Query from the visual token of the UNet,  $K_{\text{text}}$  and  $V_{\text{text}}$  denotes Key  
 516 and Value from text embeddings, all of which are projected by linear layers,  $d$  denotes the dimension  
 517 of  $Q_{\text{visual}}$ ,  $K_{\text{text}}$ , and  $V_{\text{text}}$ .

518 **Self-Attention Layer.** Self-Attention captures self-related information within visual tokens:

$$\text{Attention}(Q_{\text{visual}}, K_{\text{visual}}, V_{\text{visual}}) = \text{softmax}\left(\frac{Q_{\text{visual}}K_{\text{visual}}^T}{\sqrt{d}}\right) \cdot V_{\text{visual}} \quad (15)$$

519 where  $Q_{\text{visual}}$ ,  $K_{\text{visual}}$ , and  $V_{\text{visual}}$  separately represent the Query, Key, and Value in self-attention  
 520 layers, which are projected by linear layers. The self-attention mechanism isolates the information  
 521 flow between specific tokens by multiplying a mask  $\mathbf{M}$  to the  $Q_{\text{visual}}K_{\text{visual}}^T$ . Since  $\mathbf{M}$  is applied  
 522 before  $\text{softmax}$ , the value of the isolated position is set to negative infinity  $-\text{inf}$ .

523 **Compositional Masked Attention Layer.** Based on the attention mask  $\mathbf{M}$  that depends on layout  $\mathcal{B}$ ,  
 524 the Compositional Masked Attention can be expressed as:

$$\text{Attention}(Q_{\text{CMA}}, K_{\text{CMA}}, V_{\text{CMA}}) = \text{softmax}\left(\frac{Q_{\text{CMA}}K_{\text{CMA}}^T \odot \mathbf{M}}{\sqrt{d}}\right) \cdot V_{\text{CMA}} \quad (16)$$

525 where  $Q_{\text{CMA}}$ ,  $K_{\text{CMA}}$ , and  $V_{\text{CMA}}$  individually represent the Query, Key, and Value derived from  
 526  $\mathcal{V} \otimes \hat{\mathcal{C}}$ , achieved through linear layer projections. We insert our proposed Compositional Masked  
 527 Attention (CMA) between self-attention and cross-attention layers.

528 **A.3 Multi-Layer Sampler**

529 **Layered Scene Representation.** We decompose a controllable scene containing  $N_o$  objects into  $N_o$   
 530 layers. Different from SceneDiffusion [25], our approach involves each layer incorporating not only

531 separate latent code  $z_i$  and spatial layout  $b_i$ , but also integrating the interactive semantics  $s_i$  produced  
 532 by the SL-VAE. Here we convert the layout parameter  $b_i$  to two parts: (1) a fixed *object-centric* binary  
 533 mask  $m_i \in \{0, 1\}^{c \times w \times h}$  to solely show the geometric property of the object, and (2) a two-element  
 534 offset  $p_i = \{\mu_i, v_i\}$  to solely indicate its spatial locations, with  $\mu_i$  and  $v_i$  defining the horizontal and  
 535 vertical movement range. We sample Gaussian noise individually for the initial latent code of each  
 536 layer, i.e.,  $\mathcal{Z} = \{z_i^{(T)} \sim \mathcal{N}(0, 1)\}_{i=1}^{N_o}$ . Then we utilize the layout-converted non-overlapping masks  
 537  $\{l_i\}_{i=1}^{N_o}$  to derive the aggregated latent code  $z$  from various layers:

$$z^{(t)} = \sum_{i=1}^{N_o} l_i \odot \overline{\text{shift}}(z_i^{(t)}, p_i) \quad (17)$$

$$l_i = \overline{\text{shift}}(m_i, p_i) \prod_{j=1}^{N_i-1} (1 - \overline{\text{shift}}(m_j, p_j)), \quad (18)$$

538 where  $\odot$  denotes element-wise multiplication, and  $\overline{\text{shift}}(x, p)$  denotes spatially shifting the values  
 539 of  $x$  in the direction of  $p$ .

540 **Multi-Layer Generation** We introduce the Multi-Layer Sampler that matches our diverse layout  
 541 and semantic simulation. In contrast to SceneDiffusion [25] which scrambles the reference layouts  
 542 randomly, we sample additional  $N_l$  layouts and semantics by the proposed SL-VAE. On the one hand,  
 543 the SL-VAE ensures that the generated scene layout is reasonable. On the other hand, we take full  
 544 advantage of the paired object-level (*layouts, semantics*). Specifically, the denoising scheme consists  
 545 of four steps:

546 (a) Sampling additional  $N_l$  layouts  $\{\mathcal{B}_n = \{b_{n,i}\}_{i=1}^{N_o}\}_{n=1}^{N_l}$  and semantics  $\{\mathcal{S}_n = \{s_{n,i}\}_{i=1}^{N_o}\}_{n=1}^{N_l}$  by  
 547 the proposed SL-VAE. Note that  $N_l$  fixed seeds exist for the same scene graph. According to the  
 548 description of the layered representation, we convert the layout to get offset  $\{\mathcal{P}_n = \{p_{n,i}\}_{i=1}^{N_o}\}_{n=1}^{N_l}$ .

549 (b) Aggregating latent codes from various layers in each scene:

$$z_n^{(t)} = \sum_{i=1}^{N_o} l_i \odot \overline{\text{shift}}(z_i^{(t)}, p_{n,i}) \quad (19)$$

550 (c) Estimating the noise  $\hat{\epsilon}_n^{(t)}$  from each aggregated latent code  $z_n^{(t)}$  and gets denoised aggregated  
 551 latent code  $\hat{z}_n^{(t-1)} \in \{\hat{z}_1^{(t-1)}, \dots, \hat{z}_{N_l}^{(t-1)}\}$ :

$$\hat{\epsilon}_n^{(t)} = \sum_{i=1}^{N_o} m_{n,i} \odot \epsilon_{\theta}(z_n^{(t)}, E_{\text{CLIP}}(o_i), b_{n,i}, s_{n,i}, a_i, t), \quad (20)$$

552 where  $m_{n,i}$  is the non-overlapping mask converted by the layout  $b_{n,i}$ .

553 (d) Updating the latent code of each layer by computing the weighted average of the  $N_l$  aggregated  
 554 latent code

$$z_i^{(t-1)} = \frac{\sum_{n=1}^{N_l} \overline{\text{shift}}(l_i \odot \hat{z}_n^{(t-1)}, -p_{n,i})}{\sum_{n=1}^{N_l} \overline{\text{shift}}(l_i, -p_{n,i})} \quad (21)$$

555 where  $\overline{\text{shift}}(x, -p)$  denotes spatially shifting the values of  $x$  in the reverse direction of  $p$ .

#### 556 A.4 More Ablation Studies

557 **Graph Construction.** We conduct ablation for  
 558 graph construction in Table 6. We investigate the  
 559 impact of different graph components (i.e., CLIP,  
 560 Box, and Learnable Embeddings) by turning off  
 561 each independently. We observe that each compo-  
 562 nent improves the performance, all of which are  
 563 crucial components presented in our DisCo.

Table 6: **Ablation study** for graph construction.

Graph Type	IS $\uparrow$	FID $\downarrow$
No CLIP Emb.	20.6	23.9
No Box Emb.	21.7	22.5
No Learnable Emb.	21.9	22.2

564 **Computing Consumption.** We demonstrate the impact of our proposed CMA on the computational  
 565 complexity of the U-Net within the Stable Diffusion, as presented in Table 7. We use Floating Point

Table 7: **Ablation study** for computing consumption.

Method	FLOPs (G)	Params (M)	Time (ms)
SD-v1.5 [20]	677.5	859.4	37.9
DisCo	724.1	875.8	108.3

566 Operations (FLOPs), the number of parameters (Params), and inference time (Time) to measure  
 567 computing consumption. The FLOPs and Time metrics are conducted by processing the tensor with a  
 568 resolution of  $2 \times 4 \times 64 \times 64$  on an NVIDIA A100 GPU. Our proposed DisCo significantly improves  
 569 the controllability of the Stable Diffusion with a tolerable increase in computational cost.

### 570 A.5 More Visualization Results

571 Figure 8 showcases more generalizable generation results under consistency for graph manipulation  
 572 (i.e., node addition and attribute control) in SG2I task. In Figure 9, 10, and 11, we present more  
 573 visualization comparisons with the methods conditioned by text, layout, or scene graph, which  
 574 demonstrates the superiority of our DisCo in terms of generation rationality and controllability.

### 575 A.6 Limitations

576 The proposed CMA injects object-level information into the  
 577 diffusion model via masks from the layout, effectively miti-  
 578 gating semantic ambiguity and limiting attribute leakage. In  
 579 scenarios involving object overlap, the proposed CMA inhibits  
 580 direct interaction between the visual token and the object em-  
 581 bedding along with its attributes. Nonetheless, the attribute  
 582 information from the visual token inadvertently leaks into the  
 583 overlapping region in subsequent layers. Hence, there may be  
 584 attribute leakage among the objects, as shown in Figure 7.

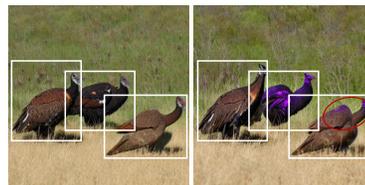

Figure 7: **Qualitative limitations** on attribute leakage of overlapping.

### 585 A.7 Broader Impacts

586 We demonstrate the superiority of our DisCo over existing generation methods based on text, layout,  
 587 and scene graphs, suggesting a potential beneficial influence on the realms of art creation and data  
 588 synthesis. Nevertheless, there remains a concern regarding the possibility of generating malicious  
 589 images or infringing copyright.

## Graph Manipulation (Node Addition and Attribute Control)

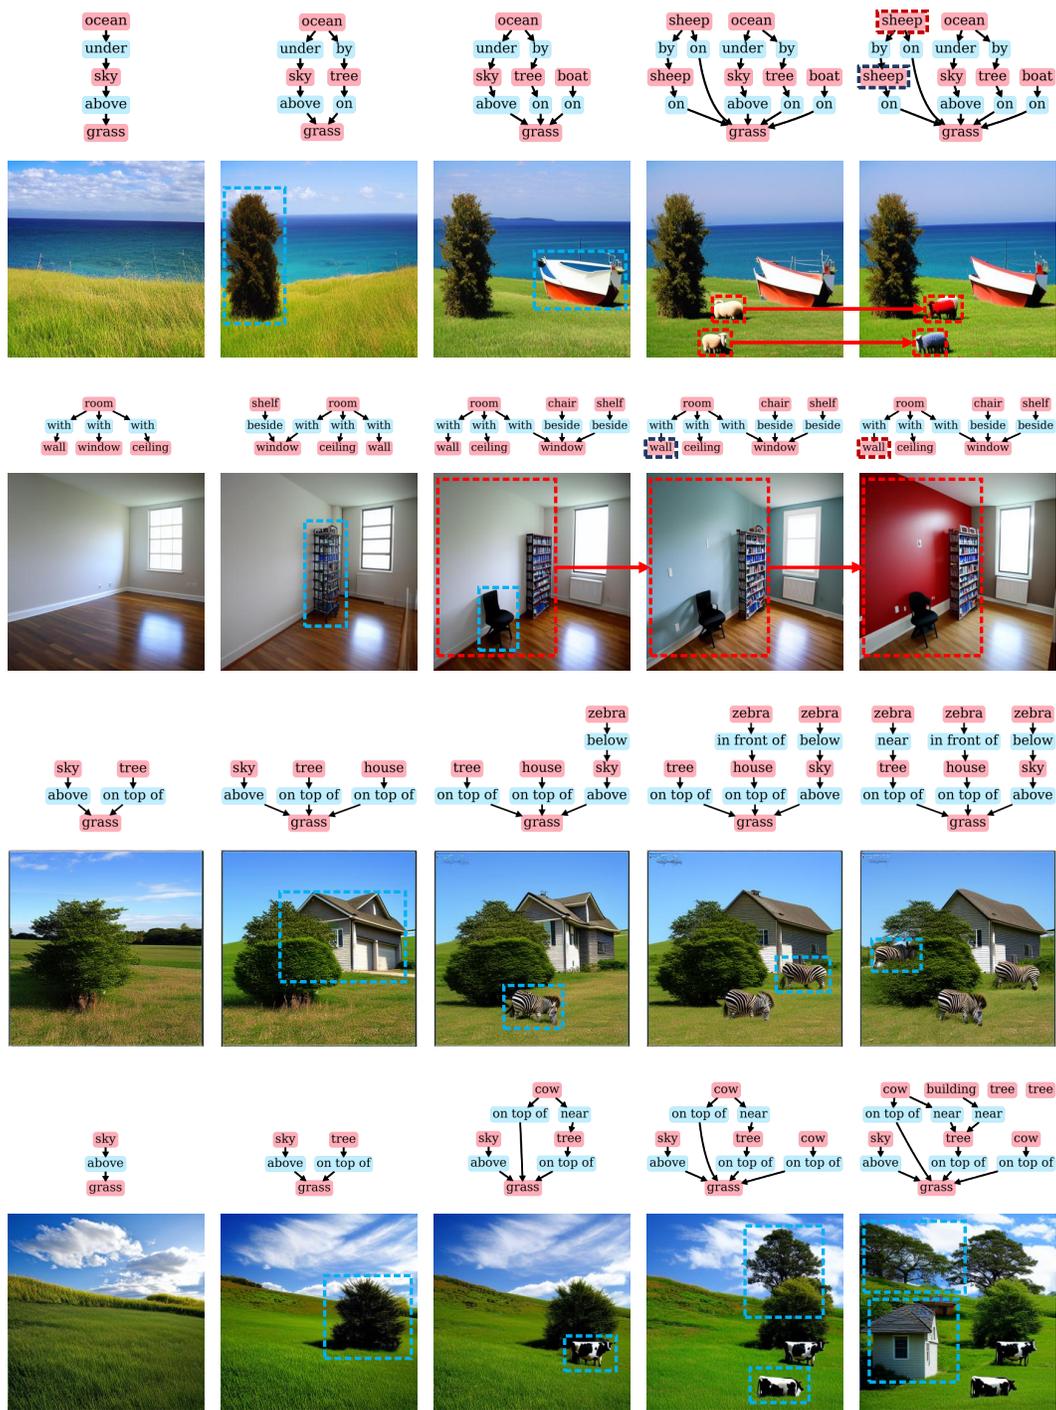

Figure 8: Generalizable Generation Samples under Consistency for Graph Manipulation.

A building in front of a mountain; a tree in front of the building

Tree zebras standing on the grass; two near the tree; one in front of the house

Two cow on top of grass; one near the tree; sky above the grass; a building near the tree

The street by the building; the car next to the truck

A teddy bear sit on the ground; another two teddy bear besides the table
