Forgetting Across Modalities: Unlearning in Multimodal Large Language Models

Abstract

Gradient conflict between forgetting and retaining objectives is a well-known obstacle in machine unlearning, where opposing gradients on shared parameters cause destructive interference. In Multimodal Large Language Models (MLLMs), cross-modal coupling entangles visual and textual representations within the same parameters, making this conflict considerably more severe. We propose **EASE** (**E**fficient **A**lignment-aware **S**elective **E**rasing), which explicitly balances the conflicting gradient directions. EASE first dynamically locates the conflicting parameters at each step by detecting opposite-sign gradients, then performs a manifold-constrained optimization within the two-dimensional subspace spanned by the task gradients to find the linear combination that maximally aligns them, yielding a valid descent direction for both objectives without any manually tuned trade-off coefficient. Non-conflicting parameters keep their standard updates, keeping the method lightweight. Experiments across multiple MLLM architectures and unlearning benchmarks show that EASE achieves superior unlearning efficiency and faster convergence while matching or surpassing existing methods in multimodal quality.

1 Introduction

Multimodal Large Language Models (MLLMs) trained on large-scale web corpora (Yuan et al., 2025; Lin et al., 2024; Alayrac et al., 2022; Wang et al., 2024a) can reproduce unauthorized, sensitive, or harmful content in both text and images, raising serious privacy, copyright, and safety concerns (Wang et al., 2025; Zhang et al., 2025; Huo et al., 2025; Liu et al., 2025). Machine unlearning (Bourtoule et al., 2021; Heng and Soh, 2024; Fan et al., 2024) aims to remove the influence of specific training data without retraining from scratch. While substantial progress has been made for classifiers and generative models (Liu et al., 2025; Huo et al., 2025; Gupta et al., 2021; Sekhari et al., 2021; Nguyen et al., 2022), a fundamental obstacle persists across all settings: the forgetting and retaining objectives push shared parameters in opposite directions, producing *conflicting gradients* that cause destructive interference and slow convergence (Heng and Soh, 2024; Wang et al., 2023a; Fan et al., 2024). As illustrated in Figure 1, when such conflicts occur, gradient propagation is blocked for both objectives, and even unrelated knowledge degrades.

(a) Conflicts.

(b) Non-Conflicts.

Figure 1: Gradient conflicts in joint forgetting and retaining. (a) Conflicting gradients block both updates and degrade unrelated knowledge (celebrity loss rises). (b) Without conflicts, gradients flow normally and performance is preserved.

Extending unlearning to Multimodal Large Language Models (MLLMs) makes this conflict considerably more severe (Liu et al., 2025; Huo et al., 2025; Li et al., 2024a). Cross-modal coupling entangles visual and textual representations within

the same parameters (Yuan et al., 2025; Cheng and Amiri, 2024; Yang et al., 2025), so a single weight typically contributes to both modalities simultaneously. Consequently, the parameter overlap between the forgetting set and the retaining set is much larger than in unimodal models, and the opposing gradient directions on these shared parameters become both more frequent and more damaging (Cheng and Amiri, 2024; Dontsov et al., 2025). Existing approaches, including Bayesian-inspired methods originally designed for generative models (Chen et al., 2021; Deepanjali et al., 2021; Schuhmann et al., 2022; Heng and Soh, 2024; Fan et al., 2024), do not explicitly model this conflict and therefore suffer from substantial efficiency limitations when applied to MLLMs.

Motivated by this observation, we propose EASE (**E**fficient **A**lignment-aware **S**elective **E**rasing), an unlearning framework that explicitly balances the conflicting directions on shared parameters. At each step, EASE dynamically locates conflicting parameters by detecting opposite-sign gradients between the forgetting and retaining objectives, and performs a manifold-constrained optimization in the two-dimensional subspace spanned by the two task gradients to obtain a valid descent direction for both objectives without any manually tuned trade-off (Sener and Koltun, 2018; Désidéri, 2012). Non-conflicting parameters retain their standard updates, keeping the method lightweight and avoiding any global alignment of the parameter space with the original model. Extensive experiments across multiple MLLM architectures and unlearning benchmarks show that EASE achieves superior unlearning efficiency and faster convergence while matching or surpassing existing methods in multimodal understanding and generation quality.

We summary our main contributions in short as follows:

- We characterize *gradient conflict on shared parameters* as a fundamental obstacle to efficient unlearning, and show that it is significantly aggravated in MLLMs by cross-modal coupling that entangles visual and textual representations within the same weights.
- We propose EASE, which detects conflicting parameters via opposite-sign gradients and resolves them by a manifold-constrained optimization in the 2D subspace spanned by the two task gradients, yielding a valid descent direction without any manually tuned trade-off.

- Extensive experiments across diverse multimodal datasets and MLLM architectures demonstrate that EASE achieves superior unlearning efficiency and faster convergence while matching or surpassing existing baselines in multimodal quality.

2 Related Work

Machine unlearning for generative model In recent years, the researchers have made efforts in unlearning of generative model. Several works proposed to unlearning from GANs by utilizing the discriminator (Kong and Chaudhuri, 2023; Chen et al., 2021; Sun et al., 2023), but these methods can't be applied to other generative models due to their mechanism only suit for paradigm of GANs. There are some works realizing unlearning of generative model by modifying the weights (Bau et al., 2020; Tarun et al., 2023), but it is still a challenge to accurately identify model weights associated to the forgetting tasks accurately. Some researchers proposed Bayesian based unlearning methods that can be applied to various generative models (Heng and Soh, 2024; Nguyen et al., 2020; Fan et al., 2024; Fu et al., 2022, 2021), but they need to trade off between forgetting the posterior distribution of data to forget and not entirely forgetting posterior distribution of the original training data to preserve the generative models' ability, causing conflicts due to the correlations between the data to forget and the original training data.

Machine unlearning for MLLMs At the early stage, multimodal machine unlearning mainly targeted vision-language models (Cheng and Amiri, 2024; Yang et al., 2025). Recent work has highlighted safety and privacy issues in VLMs: adversarial and black-box visual jailbreak strategies expose vulnerabilities in safety-aligned systems (Gong et al., 2025; Li et al., 2024b). Other studies question whether text-only unlearning suffices for multimodal safety (Chakraborty et al., 2024) and empirically show that VLMs can infer private attributes from images even without explicit human depictions (Tömekçe et al., 2024; Samson et al., 2024).

Despite these advances in VLMs, machine unlearning for full-fledged MLLMs has only been explored in recent years (Li et al., 2024a; Wang et al., 2025): SIU (Li et al., 2024a), for example, erases visual patterns in MLLMs on the real-world MMUBench dataset via multi-faceted fine-tuning.

These works mark early progress in addressing unlearning for complex multimodal settings. Several benchmarks have been proposed to systematically evaluate unlearning performance in MLLMs. MLLMU-Bench (Liu et al., 2025) evaluates MU methods designed for LLMs on fictional personal profiles, while CLEAR (Dontsov et al., 2025) extends the pure-text LLM unlearning benchmark TOFU by adding visual images generated through Photomaker (Li et al., 2024c).

3 Problem definition

We briefly formalize unlearning for Multimodal Large Language Models (MLLMs). Given a pre-trained MLLM $\mathbb{M}_\theta$ with parameters θ, and without access to the original training data, we are provided a forgetting set $D_f = \{(I_f^n, Q_f^n, A_f^n)\}_{n=1}^{N_f}$ and a retaining set $D_r = \{(I_r^n, Q_r^n, A_r^n)\}_{n=1}^{N_r}$, where each triplet contains an image, a question, and the correct answer. The goal is to fine-tune $\mathbb{M}_\theta$ into $\mathbb{M}_{\theta*}$ such that (1) $\mathbb{M}_{\theta*}(I_f, Q_f) \neq A_f$ on D_f and (2) $\mathbb{M}_{\theta*}(I_r, Q_r) \approx A_r$ on D_r. We treat parameters elementwise as $\theta = \{\theta_1, \ldots, \theta_k\}$.

Existing MLLM unlearning methods (Liu et al., 2025) optimize separate losses on D_f and D_r, but neglect their correlation, which produces conflicting gradient updates that hurt convergence and efficiency. Saliency-based methods (Huo et al., 2025) mitigate this by selectively updating parameters according to a fixed saliency map computed before unlearning, which fails to adapt as θ evolves. We instead identify the parameter sets θ_f and θ_r relevant to forgetting and retaining *dynamically* at each step: efficient unlearning preserves θ_r and updates θ_f, while the key challenge lies in the overlap $\Omega(\theta_f, \theta_r)$, where the two objectives induce conflicting gradient directions. Explicitly balancing the updates in this overlap accelerates unlearning while preserving performance on D_r.

4 Methodology

4.1 Theoretical Analysis

For brevity, we denote $x_f = (I_f, Q_f, A_f)$ and $x_r = (I_r, Q_r, A_r)$ to represent the image-question-answer triplets for forgetting and retaining data, respectively. The optimization objective for MLLM unlearning is to minimize the expected loss functions $\mathcal{L}_f$ and $\mathcal{L}_r$ over the distributions of the forgetting dataset $p(D_f)$ and retaining dataset $p(D_r)$:

$$\mathcal{O}_1 = \min_{\{\theta_f, \theta_r\}} \mathbb{E}_{p(D_f)}[\mathcal{L}_f(x_f; \theta_f)] + \mathbb{E}_{p(D_r)}[\mathcal{L}_r(x_r; \theta_r)] \tag{1}$$

Since $p(D_f)$ and $p(D_r)$ are unavailable and the two tasks share parameters (Sener and Koltun, 2018), a natural alternative is to optimize them jointly:

$$\mathcal{O}_2 = \min_\theta \frac{1}{N_f + N_r} \left[\sum_{i=1}^{N_f} \mathcal{L}_f(x_f^i; \theta) + \sum_{i=1}^{N_r} \mathcal{L}_r(x_r^i; \theta) \right] \tag{2}$$

However, this approach still overlooks the correlation between data to forget and data to retain. It may hinder convergence as the gradients of the two loss terms in Eq. (2) may point in opposite directions. According to PAC-Bayesian theory (McAllester, 1998), there exists an error $\epsilon(N, \zeta) \geq 0$ with probability $1 - \zeta$ that decreases monotonically with the number of training samples N (detailed proof in Appendix C). We obtain the following proposition:

Proposition 4.1. *The bound between optimization objectives $\mathcal{O}_1$ and $\mathcal{O}_2$:*

$$|\mathcal{O}_1 - \mathcal{O}_2| \leq \mathbb{E}_{p(D_f)}[\mathcal{D}(\mathbb{M}_{\theta_f}(x_f), \mathbb{M}_{\theta_e}(x_f))] + \mathbb{E}_{p(D_r)}[\mathcal{D}(\mathbb{M}_{\theta_r}(x_r), \mathbb{M}_{\theta_e}(x_r))] + \epsilon(N_f + N_r, \zeta) \tag{3}$$

where θ_e denotes the optimal solution of Eq. (2), $\mathbb{M}_\theta$ denotes the MLLM with parameters θ, and $\mathcal{D}(\cdot, \cdot)$ measures the divergence between model outputs.

Considering both the differences and connections between data to forget and data to retain, we rewrite the optimization objective as:

$$\mathcal{O}^* = \min_{\{\theta_f, \theta_r, \theta_e\}} \frac{1}{N_f} \sum_{i=1}^{N_f} \mathcal{L}_f(x_f^i; \theta_f) + \frac{1}{N_r} \sum_{i=1}^{N_r} \mathcal{L}_r(x_r^i; \theta_r)$$
$$\text{subject to } |\mathbb{E}_{p(D_f)}[\mathcal{D}(\mathbb{M}_{\theta_f}(x_f), \mathbb{M}_{\theta_e}(x_f))]| \leq \xi,$$
$$|\mathbb{E}_{p(D_r)}[\mathcal{D}(\mathbb{M}_{\theta_r}(x_r), \mathbb{M}_{\theta_e}(x_r))]| \leq \xi \tag{4}$$

The constant ξ controls the closeness between model behaviors. A larger ξ allows more task-specific specialization. The expectations in Eq. (4) cannot be calculated directly due to inaccessibility of the probability distributions. However, if the function is Lipschitz in the parameterization, the divergence between models can be measured by the distance between parameters (Cervino et al., 2021). We obtain:

Proposition 4.2. *The MLLM can be viewed as a parametric function. Under Lipschitz continuity:*

$$\mathbb{E}_{p(D_f)}[\mathcal{D}(\mathbb{M}_{\theta_f}(x_f), \mathbb{M}_{\theta_e}(x_f))] \leq L\|\theta_f - \theta_e\|,$$
$$\mathbb{E}_{p(D_r)}[\mathcal{D}(\mathbb{M}_{\theta_r}(x_r), \mathbb{M}_{\theta_e}(x_r))] \leq L\|\theta_r - \theta_e\| \tag{5}$$

Figure 2: Illustration of gradient conflicts in unlearning methods. (a) Naive approach: conflicting gradients occur across all forgetting-related parameters θ_f. (b) Existing methods: conflicts are reduced to the parameter overlap $\theta_f \cap \theta_r$ but still use heuristic averaging. (c) Our method: we explicitly identify conflicting parameters $\theta_{f,r}^t$ where gradients have opposite signs, then apply manifold-constrained optimization to find the least-conflicting update direction, achieving faster and more stable convergence.

where L is the Lipschitz constant.

Proposition 4.2 reduces the constrained problem in Eq. (4) to controlling the two parameter distances $\|\theta_f - \theta_e\|$ and $\|\theta_r - \theta_e\|$ *jointly*. This bound directly dictates two design principles that drive the rest of our method. *(i)* Coordinates outside the overlap of θ_f and θ_r contribute to only one of the two distances, so following the corresponding task gradient is already optimal; conflicts can therefore be confined to the overlap, motivating the dynamic identification rule in Section 4.2. *(ii)* On the overlapping coordinates the two distances are coupled and a single update direction must shrink both simultaneously, this is precisely a constrained two-objective problem whose feasible set is the span of the task gradients, leading to the manifold-constrained direction search in Section 4.3. The remainder of this section operationalizes these two principles.

4.2 Partial Parameter Identification

Following design principle *(i)* derived from Proposition 4.2, we only need to *partially align* parameters between the unlearned and the pre-trained model: the bound in Eq. (5) stays tight as long as we control the per-coordinate contributions to $\|\theta_f - \theta_e\|$ and $\|\theta_r - \theta_e\|$. Because these distances admit per-coordinate decompositions, the constrained objective in Eq. (4) can be solved by keeping forgetting- and retaining-only coordinates on their respective task gradients, and intervening only on coordinates that simultaneously enlarge *both* distances. The latter are exactly the parameters where the two task gradients pull θ_e in opposite directions, which we identify dynamically below.

Following standard MLLM unlearning practice (Heng and Soh, 2024), we instantiate $\mathcal{L}_f$ and $\mathcal{L}_r$ as auto-regressive negative log-likelihoods, applied with gradient ascent on D_f (to push outputs away from A_f) and gradient descent on D_r (to keep outputs aligned with A_r):

$$\mathcal{L}_f = \frac{1}{N_f} \sum_{i=1}^{N_f} \sum_{t=1}^{|A_f^i|} -\log p(a_t^i | I_f^i, Q_f^i, a_{<t}^i; \theta^*) \quad (6)$$

where a_t^i denotes the t-th token in answer A_f^i, and $a_{<t}^i$ represents all preceding tokens.

During the unlearning process, it is crucial to preserve the model's knowledge on the retaining set D_r. We achieve this by replaying data from D_r during fine-tuning, ensuring the model maintains its ability to generate correct answers for retained knowledge. Specifically, we want the unlearned model $\mathbb{M}_{\theta^*}$'s output distribution on (I_r, Q_r) to remain close to the original model $\mathbb{M}_\theta$'s distribution, preserving the correct answer generation capability. We define the retaining loss using the same auto-regressive formulation:

$$\mathcal{L}_r = \frac{1}{N_r} \sum_{i=1}^{N_r} \sum_{t=1}^{|A_r^i|} -\log p(a_t^i | I_r^i, Q_r^i, a_{<t}^i; \theta^*) \quad (7)$$

By applying standard gradient descent on $\mathcal{L}_r$, we maintain the model's ability to generate correct answers for the retaining set. Through this optimization, the parameters θ_r related to the retaining task should remain close to their original values in θ, preserving the model's multimodal capabilities on non-target knowledge.

To achieve the objectives outlined in Equations (6) and (7), the posterior distribution of D_r

on the unlearned model $G_{\theta*}$ should remain close to that on the original model G_θ, while the opposite holds for D_f. In terms of model parameters, this implies that parameters θ_r associated with the retaining task should stay close to their original values in θ, whereas parameters θ_f associated with the forgetting task should deviate significantly from their counterparts in θ. Let θ_t^* denote the model parameters at the t-th gradient step, with corresponding loss functions $\mathcal{L}_f^t$ and $\mathcal{L}_r^t$ for forgetting and retaining, respectively. A key challenge arises for parameters in the overlap $\theta_f^t \cap \theta_r^t$, where gradients may point in opposite directions. To identify such conflicts, we define a conflict indicator for each parameter $\theta_i \in \theta_t^*$ as:

$$C_i^t = \nabla_{\theta_i}\mathcal{L}_f^t \odot \nabla_{\theta_i}\mathcal{L}_r^t \qquad (8)$$

where $\odot$ denotes element-wise multiplication. Parameters with $C_i^t < 0$ experience true gradient conflicts, as their forgetting and retaining gradients have opposite signs. We denote the set of all conflicting parameters as:

$$\theta_{f,r}^t = \{\theta_i \in \theta_f^t \cap \theta_r^t \mid C_i^t < 0\} \qquad (9)$$

This formulation precisely identifies the coordinates where a single update direction must trade off forgetting and retaining — exactly the overlapping coordinates flagged by design principle **(ii)** in Section 4.1. In Section 4.3 we resolve them by minimizing the joint distance bound of Proposition 4.2 over the two-dimensional subspace spanned by g_f^t and g_r^t.

4.3 Manifold-Constrained Conflicts Mitigation

Design principle *(ii)* from Section 4.1 requires, on the overlapping coordinates $\theta_{f,r}^t$, an update direction that jointly controls $\|\theta_f - \theta_e\|$ and $\|\theta_r - \theta_e\|$ in Proposition 4.2. The set of directions that can decrease *both* distances at the same time is exactly the span of the two task gradients restricted to $\theta_{f,r}^t$, which forms a two-dimensional feasible manifold. We therefore replace heuristic averaging with an explicit search over this manifold, turning the constrained objective in Eq. (4) into a tractable direction-finding problem. For the conflicting parameter set $\theta_{f,r}^t$ identified in Equation (9), we extract the corresponding gradients for both tasks. Let $g_f^t \in \mathbb{R}^d$ and $g_r^t \in \mathbb{R}^d$ denote the gradients of the forgetting and retaining losses restricted to

these conflicting parameters:

$$g_f^t = \nabla_{\theta_{f,r}^t}\mathcal{L}_f^t, \; g_r^t = \nabla_{\theta_{f,r}^t}\mathcal{L}_r^t \qquad (10)$$

where $d = |\theta_{f,r}^t|$ is the number of conflicting parameters. We construct the gradient matrix $G^t = [\, g_f^t, g_r^t \,] \in \mathbb{R}^{d \times 2}$ whose columns are the two task gradients.

Within this 2-D manifold, we look for the linear combination $\tilde{g}^t = w_f g_f^t + w_r g_r^t$ that minimizes destructive interference across the d conflicting coordinates:

$$\mathbf{w}^\star = \arg\min_{\mathbf{w} \in \mathbb{R}^2} \left\| \sum_{i=1}^{d}[G^t\mathbf{w}]_i \right\|_2^2 \qquad (11)$$

where $[G^t\mathbf{w}]_i$ denotes the i-th element of the vector $G^t\mathbf{w} \in \mathbb{R}^d$, and the summation aggregates over all d conflicting parameters. This objective identifies the combination that achieves maximal constructive alignment between the task gradients, thereby reducing destructive interference.

To solve this optimization efficiently, we employ a rotation-based parameterization. By introducing a rotation angle $\alpha \in [0, 2\pi)$ and defining the rotation matrix $M(\alpha) = \begin{bmatrix} \cos(\alpha) & -\sin(\alpha) \\ \sin(\alpha) & \cos(\alpha) \end{bmatrix}$, we can explore all possible linear combinations by optimizing α via gradient descent. The optimized combined gradient is then:

$$\tilde{g}^t = G^t M(\alpha^\star)_{:,1} = \cos(\alpha^\star)g_f^t + \sin(\alpha^\star)g_r^t \qquad (12)$$

where $\alpha^\star$ minimizes Eq. (11).

Because $\tilde{g}^t \in \text{span}(g_f^t, g_r^t)$, every step decreases both $\|\theta_f - \theta_e\|$ and $\|\theta_r - \theta_e\|$ on the conflicting coordinates, tightening the bound in Eq. (5). The trade-off $\mathbf{w}^\star$ is fixed by the gradient geometry and requires no manual tuning.

Parameter Update Strategy We apply the optimized gradient direction $\tilde{g}^t$ exclusively to the conflicting parameters $\theta_{f,r}^t$, while non-conflicting parameters retain their original task-specific gradients. This yields a piecewise update rule:

$$\nabla_{\theta_t} = \begin{cases} \tilde{g}^t & \text{if } \theta_t \in \theta_{f,r}^t \\ \nabla_{\theta_t}\mathcal{L}_f^t + \nabla_{\theta_t}\mathcal{L}_r^t & \text{otherwise} \end{cases} \qquad (13)$$

The model parameters are then updated via gradient descent:

$$\theta_{t+1} = \theta_t - \eta\nabla_{\theta_t} \qquad (14)$$

where $\eta > 0$ denotes the learning rate.

Table 1: Main results on MLLMU-Bench and CLEAR benchmarks. Performance is reported for the Forget, Retain, and Real-world splits, comparing our method with several baselines across multiple MLLM architectures. Lower values indicate better forgetting on the Forget set (↓), while higher values indicate better retention and generalization on the Retain and Real-world sets (↑).

| Method | MLLMU-Bench | | | | | | | | | CLEAR | | | | | |

5 Experiment

5.1 Experiment Settings

Benchmark: We evaluate on two multimodal unlearning benchmarks, MLLMU-Bench (Liu et al., 2025) and CLEAR (Dontsov et al., 2025). MLLMU-Bench contains fictitious personal profiles, each paired with a portrait and 14 multiple-choice questions. We report the results on the Forget, Retain, and Real-world splits. CLEAR is built on TOFU (Maini et al., 2024) and augments each fictional author profile with several face images and captions generated by GPT-4o (Achiam et al., 2023), we report the results on the Forget, Retain, Real-face and Real-world splits.

Baseline: As previous work done (Liu et al., 2025; Huo et al., 2025), we compare our method with several commonly used unlearning baselines, including GA_Diff (Liu et al., 2022), KL_Min (Nguyen et al., 2020), NPO (Zhang et al., 2024) and MMUnlearner (Huo et al., 2025). More details about the baseline methods can refer to Appendix D.

Evaluation Metric: To evaluate cross-modal unlearning, we follow prior work and perform unlearning on both benchmarks. We primarily report unlearning results on VQA tasks, as the VQA data provides image-grounded supervision for erasing visual associations, offering better evidence of cross-modal unlearning performance. On MLLMU-Bench, we report Classification Accuracy, ROUGE-L, and Cloze Accuracy on the Forget, Retain, and Real-world splits. On CLEAR, we report Classification Accuracy and ROUGE-L for the VQA task on the Forget and Retain splits, and Classification Accuracy on the Real-face and Real-world splits.

Implementation setting: We choose LLaVA-1.5-7B, LLaVA-1.5-13B, Qwen2.5-VL-3B, and Qwen2.5-VL-7B as the pre-trained models. For the fairness of the experiments, for all the baselines and our method, we fine-tune models for 1 epochs with batch size 4 (gradient accumulation 1) and learning rate 10^{-5} with AdamW optimizer. And we use bf16 mixed precision for the fine-tuning process for all the models. We adopt a linear learning-rate scheduler with 0 warmup steps and apply LoRA with rank $r = 16$, $\alpha = 16$, and dropout 0.05. All experiments are conducted using 4 Nvidia H800

Figure 3: Qualitative comparison of unlearning methods on MLLMU-Bench. We show model responses on (left upper) forget set, (middle upper) retain set, and (right) real-world set. Our method successfully forgets target entities while maintaining coherent and accurate responses on retain and real-world data, outperforming baselines that fail to preserve retention quality or damage general capabilities.

GPUs with 80 GB memory. More implementation settings can refer to Appendix D. For the manifold-constrained gradient optimization, we initialize the rotation angle α as 0.25 (we evaluate the effect of α's initial value in Appendix E.4), and we optimize α via SGD optimizer with learning rate 10^{-2} and learning step 10 (More implementation details can be found in Appendix D.1).

5.2 Main Results

Quantitative Results We present comprehensive quantitative results in Table 1, evaluating our method against four strong baselines across four MLLM architectures on two benchmarks. First, our partial parameter identification (Section 4.2, Equation 9) dynamically detects conflicting parameters where $C_i^t < 0$, enabling targeted updates that preserve retention significantly better than baseline methods (e.g., 31.41% vs. 28.54% retain accuracy on LLaVA-1.5-7B compared to Grad_Diff, and 41.13% vs. 12.91% compared to MMUnlearner on CLEAR). This demonstrates that identifying truly conflicting parameters prevents collateral damage to non-target knowledge. Second, our manifold-constrained gradient optimization (Section 4.3, Equation 11) finds optimal linear combinations within the gradient manifold, achieving better forget-retain balance than alternative multi-task methods like CAGrad and PCGrad

(Table 2). The consistent performance across architectures (LLaVA and Qwen families) and benchmarks confirms that both components work synergistically to enable principled conflict resolution.

Qualitative Results Figure 3 visualizes model (Qwen2.5-VL-7B) responses on MLLMU-Bench across forget, retain, and real-world sets. Our method successfully produces uninformative responses on the forget set (erasing target visual-textual associations) while maintaining correct, coherent answers on the retain set, validating our selective parameter preservation strategy. On the real-world set, our method demonstrates superior generalization to unseen entities with responses comparable to the vanilla model, confirming that our conflict-aware optimization preserves general multimodal reasoning without collateral damage to model capabilities. More comparison samples can be found in Appendix E.

5.3 Ablation Study

We conduct ablation studies on LLaVA-1.5-7B to validate the contribution of each component in our method. Table 2 presents results for ablation variants compared to our full method. Table 2 demonstrates that both components are essential for effective unlearning. Removing partial parameter identification (w/o Partial Param) causes significant retention degradation (20.67% vs.

(a) Loss Curve

(b) Gradient weights

(c) Overlap Ratio / Cosine Similarity

Figure 4: Training dynamics during unlearning on LLaVA-1.5-7B. (a) Loss curves show that conflicts cause retaining loss to stagnate until resolved. (b) The rotation angle α adapts dynamically to find optimal gradient combinations. (c) Conflict indicators (overlap ratio and cosine similarity) evolve as the method resolves gradient conflicts through manifold-constrained optimization.

31.41%), as indiscriminately updating all parameters damages non-target knowledge. Replacing our manifold-constrained optimization with alternative methods (CAGrad: 24.31% retain; PCGrad: 29.17% retain) also degrades performance, confirming the importance of finding optimal linear combinations within the gradient manifold (Equation 11). Removing both components (w/o both) yields poor retention (21.18%). Our full method achieves the best forget-retain balance (20.00% forget, 31.41% retain), demonstrating that conflicting parameter identification (Equation 9) and manifold-constrained gradient optimization work synergistically. Due to the space limit, we present the samples and detailed analysis of ablation study in Appendix E.3.

Table 2: Ablation study on MLLMU-Bench with LLaVA-1.5-7B. We evaluate the contribution of Partial Parameter Identification and Conflict Mitigation.

| Method | MLLMU-Bench (LLAVA-1.5-7B) | | | | | |
| | Forget Set | | | Retain Set | | |
	Class Acc ($\downarrow$)	Rogue Score ($\downarrow$)	Cloze Acc ($\downarrow$)	Class Acc ($\uparrow$)	Rogue Score ($\uparrow$)	Cloze Acc ($\uparrow$)
w/o Partial Param	21.66	0.058	2.083	20.67	0.039	8.133
w/o Conflict Mitigation						
w/ CAGrad	24.16	0.052	10.41	24.31	0.044	3.902
w/ PCGrad	33.33	0.093	4.166	29.17	0.067	1.687
w/o both	22.50	0.058	10.41	21.18	0.036	2.109
Ours	**20.00**	**0.021**	2.083	**31.41**	**0.081**	**11.70**

5.4 Analysis of Gradient Conflict Dynamics

To elucidate how our manifold-constrained optimization dynamically resolves gradient conflicts, we visualize the training dynamics in Figure 4. During the conflict phase (approximately iterations 200-300, highlighted in Figure 4a), the retaining loss plateaus, indicating gradient interference. Our method adaptively modulates the rotation matrix to identify the optimal direction within the gradient manifold, as evidenced by the pronounced variations in the rotation matrix (Figure 4b). Concurrently, both the overlap ratio of conflicting parameters and the cosine similarity between task gradients exhibit significant fluctuations (Figure 4c), reflecting the dynamic parameter identification process. Upon conflict resolution (post-iteration 300), the optimization stabilizes: both forgetting and retaining losses resume normal descent trajectories, and the rotation matrix variations diminish, demonstrating successful conflict mitigation through principled manifold-constrained optimization.

6 Conclusion

We revisit machine unlearning through the lens of gradient conflict between forgetting and retaining objectives, a long-standing obstacle that becomes considerably more severe in Multimodal Large Language Models (MLLMs), where cross-modal coupling entangles visual and textual representations within the same parameters. To address it, we propose EASE (**E**fficient **A**lignment-aware **S**elective **E**rasing). EASE first detects conflicting parameters through opposite-sign gradients, then resolves them with manifold-constrained optimization in the two-dimensional subspace spanned by the two task gradients, producing a valid descent direction for both objectives without any manually tuned trade-off. Non-conflicting parameters follow standard updates, which keeps the method lightweight. Experiments across multiple MLLM architectures and unlearning benchmarks show that EASE improves unlearning efficiency and convergence speed while surpassing existing methods in multimodal quality.

7 Limitation

Our method still has several limitations. First, EASE resolves conflicts by using first-order gradient signals and a two-dimensional subspace spanned by the forgetting and retaining gradients, which may not fully capture more complex optimization geometry in very large models or highly heterogeneous multimodal data. Second, although our experiments cover multiple MLLM architectures and benchmarks, they are still limited to the evaluated settings, and broader validation on larger-scale real-world unlearning scenarios is needed. Finally, like most post-hoc unlearning methods, our approach improves empirical forgetting behavior but does not provide a formal guarantee of complete removal of all target knowledge.

A Broader Impact Statement

Our work aims to advance safe and responsible machine unlearning in generative models, helping users remove specific information when desired. This technology has the potential for positive impact by supporting data privacy and compliance, but it should be applied with care to avoid malicious misuse or unintended erasure of valuable knowledge.

B Related Work of Machine Unlearning

Machine unlearning dedicates to enabling the removal of specific data from trained machine learning models (Bourtoule et al., 2021; Nguyen et al., 2022), encompasses methods ranging from data reorganization to direct model manipulation. While some approaches focus on preventing model learning by reorganizing data or constructing fake data (Felps et al., 2020; Tarun et al., 2023; Zhang et al., 2022; Cao and Yang, 2015), they often introduce extra information that impacts learning. Some researchers tried to unlearn sample through manipulating the model directly (Baumhauer et al., 2022; Golatkar et al., 2020; Sekhari et al., 2021; Wang et al., 2024b, 2023b), *i.e.*, modifying weights to remove sample information or adjusting model updates based on data statistics during training (Golatkar et al., 2020; Sekhari et al., 2021). Notably, research primarily focuses on unlearning for classification models, with relatively less attention to generative models, which is still in its early stages.

C Theory Proof

C.1 PAC Assumption

To derive the bound between solutions of the multi-task unlearning problem, we introduce the following assumptions. Recall from the main text that $x_f = (I_f, Q_f, A_f)$ and $x_r = (I_r, Q_r, A_r)$ denote the image-question-answer triplets for forgetting and retaining data, respectively.

Assumption C.1. The MLLM G_θ is probably approximately correct. For all $\theta \in \Theta$ with probability $1 - \delta$ over independent draws $x_n \sim p$:

$$|\mathbb{E}[\mathcal{L}(x, \theta)] - \frac{1}{N}\sum_{i=1}^{N}\mathcal{L}(x_n, \theta)| \le \epsilon(N, \delta) \quad (15)$$

Assumption C.2. The loss function $\mathcal{L}(\cdot, \theta)$ is M-Lipschitz continuous.

Assumption C.1 is a generalization of the law of large numbers for iid samples, where the error is of order $1/N$. Under these assumptions, we obtain the following proposition:

Proposition C.3. *The bound between optimization objectives $\mathcal{O}_1$ and $\mathcal{O}_2$ is:*

$$\begin{aligned} |\mathcal{O}_1 - \mathcal{O}_2| \le &\mathbb{E}_{p(D_f)}[\mathcal{D}(G_{\theta_f}(x_f), G_{\theta_e}(x_f))]+ \\ &\mathbb{E}_{p(D_r)}[\mathcal{D}(G_{\theta_r}(x_r), G_{\theta_e}(x_r))]+ \\ &\epsilon(N_f + N_r, \zeta) \end{aligned} \quad (16)$$

where θ_e denotes the optimal solution of Eq. (2), G_θ denotes the MLLM with parameters θ, and $\mathcal{D}(\cdot, \cdot)$ measures the divergence between model outputs.

Equation (16) is a direct application of Assumption C.1 over the average probability distribution and Lipschitz Assumption C.2 over the solutions.

Note that under Lipschitz continuity in the parameterization, there exists a connection between functional and parametric constraints:

Proposition C.4. *The MLLM can be viewed as a parametric function. Under Lipschitz continuity:*

$$\begin{aligned} \mathbb{E}_{p(D_f)}[\mathcal{D}(G_{\theta_f}(x_f), G_{\theta_e}(x_f))] \le L\|\theta_f - \theta_e\|, \\ \mathbb{E}_{p(D_r)}[\mathcal{D}(G_{\theta_r}(x_r), G_{\theta_e}(x_r))] \le L\|\theta_r - \theta_e\| \end{aligned} \quad (17)$$

where L is the Lipschitz constant.

By enforcing constraints on parameters, we can remove the expectation and dependency on the distribution $p(\cdot)$.

C.2 The PAC-Bayesian Theory

PAC-Bayesian theory (McAllester, 1998) quantifies the trade-off between empirical risk minimization and model complexity, providing insights into generalization ability. Given a hypothesis class $\mathcal{H}$, the training set $D = \{x_1, \ldots, x_n\}$ iid sampled from distribution $\hat{p}$ over instance space $\mathcal{S}$, and real-valued loss function $\mathcal{L} : \mathcal{H} \times \mathcal{S} \longrightarrow [0, \infty)$, PAC-Bayes provides generalization bounds for any posterior $q \in \mathcal{M}_+^1(\mathcal{H})$, where $\mathcal{M}_+^1(\mathcal{H})$ is the set of probability measures on $\mathcal{H}$. The generalization bounds depend on the empirical performance of q and its closeness to a chosen prior distribution p. The empirical risk of posterior distribution q is:

$$\mathcal{R}_s(q) = \mathbb{E}_{h \sim q(h)}\left[\frac{1}{n}\sum_{i=1}^{n}\mathcal{L}(h, x_i)\right] \quad (18)$$

and the true risk of q is:

$$\mathcal{R}(q) = \mathbb{E}_{h \sim q(h)}[\mathbb{E}_{x \sim \hat{p}}\mathcal{L}(h, x)] \quad (19)$$

Before introducing the PAC-Bayesian bound, the posterior q and loss function $\mathcal{L}$ must satisfy Assumption C.5.

Assumption C.5. There exists a constant $K > 0$ and a family $\mathcal{E}$ of functions $\mathcal{H} \to \mathbb{R}$ such that for any $x_1, x_2 \in \mathcal{S}$:

$$d_{\mathcal{E}}(q(h|x_1), q(h|x_2)) \geq K d(x_1, x_2) \qquad (20)$$

and the loss function $\mathcal{L}(\cdot, x) : \mathcal{H} \to \mathbb{R}$ is in $\mathcal{E}$.

For bounded loss functions, the PAC-Bayesian bound (Catoni, 2003) is defined in Theorem C.6:

Theorem C.6. *For a probability measure $\hat{p}$ on $\mathcal{S}$ and loss function $\mathcal{L} : \mathcal{H} \times \mathcal{S} \longrightarrow [0,1]$, with probability at least $1 - \delta$ over n random samples $\hat{S}$ drawn from $\hat{p}$, the following holds for any posterior distribution $q \in \mathcal{M}_+^1(\mathcal{H})$:*

$$\mathcal{R}(q) \leq \mathcal{R}_s(q) + \frac{\lambda}{8n} + \frac{D_{KL}(q||p) + \log \frac{1}{\delta}}{\lambda} \quad (21)$$

where $\delta \in (0,1)$ and $\lambda > 0$.

Theorem C.6 predicts the behavior of $q(h|x)$ for any $x \sim \hat{p}$ when posterior q is learned using training samples D.

D   Experiment Setting

D.1   Implementation Details

We conduct experiments on three state-of-the-art vision-language models: LLaVA-7B, LLaMA-3.2-Vision, and Qwen2-VL. We use these pretrained models solely for research experiments in multimodal unlearning and do not repurpose or redistribute them beyond this research setting. Following standard unlearning protocols, we split the training data into forget and retain sets with ratios of 5% and 95%, respectively. All models are fine-tuned using Low-Rank Adaptation (LoRA) with rank $r = 16$, $\alpha = 16$, and dropout of 0.05 applied to all linear layers. We train for 1 epochs using AdamW optimizer with learning rate 1×10^{-5}, batch size 4, and gradient clipping at norm 1.0. Forget and retain batches are interleaved with a frequency of 2 during training. All experiments are conducted on NVIDIA H800 GPUs using mixed precision (bfloat16) training with the Hugging Face Accelerate library for distributed optimization.

D.2   The description of Baseline methods

- GA_Diff (Liu et al., 2022) is a gradient-ascent unlearning baseline that optimizes a joint objective over D_f and D_r to trade off forgetting and retention.

- KL_Min (Nguyen et al., 2020) preserves retention by matching the updated model's predictions on D_r to the original model via KL minimization, while encouraging divergence on D_f.

- NPO (Zhang et al., 2024) casts unlearning as preference optimization by treating D_f as dispreferred and using an oracle model fine-tuned on D_r.

- MMUnlearner (Huo et al., 2025) performs entity-level visual unlearning in MLLMs via geometry-constrained gradient ascent with saliency-based parameter updates, aiming to remove target visual patterns while preserving textual knowledge.

D.3   Details of Benchmarks

To evaluate the effectiveness of multimodal unlearning, we adopt two recent benchmarks: **CLEAR** and **MLLMU-Bench**. Both benchmarks are designed to assess a model's ability to forget targeted information while preserving general utility, but they differ in scope, construction, and evaluation focus. These existing benchmarks are used only for academic research and evaluation of multimodal unlearning, which is consistent with their intended purpose as benchmark resources.

CLEAR (Dontsov et al., 2025) is an early benchmark tailored for multimodal unlearning, constructed around fictitious individuals with associated textual descriptions and synthesized visual content. It evaluates unlearning through multimodal question–answering tasks that jointly involve image and text inputs. CLEAR emphasizes character-level forgetting and highlights the challenges of unlearning in visually grounded representations, where visual features may introduce instability during optimization.

MLLMU-Bench (Liu et al., 2025) is a more comprehensive benchmark targeting multimodal large language models (MLLMs). It includes a larger set of fictitious profiles as well as public celebrity profiles, with carefully designed question–answer pairs spanning unimodal and multimodal

Table 3: Comparison between CLEAR and MLLMU-Bench for multimodal unlearning evaluation.

Aspect	CLEAR	MLLMU-Bench
Target models	Multimodal models	Multimodal LLMs
Entities	Fictitious individuals	Fictitious + public profiles
Modalities	Text + image	Text + image
Primary task	Multimodal QA	Multimodal / unimodal QA
Evaluation focus	Character-level unlearning	Efficacy, generalization, utility
Scale	Moderate	Large
Visual stability	Sensitive to synthesis	More controlled
Benchmark goal	Early MMU analysis	Comprehensive MMU evaluation

settings. MLLMU-Bench explicitly evaluates unlearning performance across multiple dimensions, including forgetting efficacy, generalization to related queries, and post-unlearning model utility, making it suitable for systematic and large-scale evaluation.

E   Experiment Results

E.1   More Comparison Results

E.2   Additional Qualitative Results

To provide comprehensive qualitative evaluation of EASE across different model architectures, we present additional visualization results on MLLMU-Bench. In the main paper, we showed results for Qwen2.5-VL-7B (Figure 3). Here we present qualitative comparisons with baselines for three additional architectures: LLaVA-1.5-7B (Figure 7), LLaVA-1.5-13B (Figure 8), and Qwen2.5-VL-3B (Figure 9).

For each model, we visualize three aspects: (a) performance on the retain set, demonstrating that EASE preserves the model's ability to answer questions about retained knowledge, (b) performance on the forget set, showing effective forgetting where the model produces uninformative or incorrect responses, and (c) performance on celebrity set (real-world generalization), validating that the model maintains general capabilities on unrelated data. These visualizations consistently demonstrate that EASE achieves superior forget-retain balance across different architectures while preserving real-world performance.

E.3   Detailed Ablation Analysis

To provide deeper insights into how each component of EASE contributes to the overall performance, we present detailed ablation results on LLaVA-1.5-7B with MLLMU-Bench. We analyze both the final performance metrics (Figure 10) and the training dynamics through loss curves (Figure 5). These visualizations help explain why certain ablation variants fail and validate the necessity of both components.

E.3.1   Performance Metrics Comparison

Figure 10 compares the final performance across different ablation variants. The top row shows forgetting performance: our method achieves the lowest scores across metrics, indicating effective forgetting. The bottom row shows retaining performance: our method achieves the highest scores, demonstrating superior knowledge preservation. Alternative methods (CAGrad, PCGrad) and incomplete variants (w/o Partial Param, w/o Both) fail to achieve this balance, either degrading retention or compromising forgetting effectiveness.

E.3.2   Training Dynamics Analysis

Figure 5 presents the loss curves during training for each ablation variant, revealing why different components are essential:

w/o Partial Param (Figure 5a): Without partial parameter identification, all parameters are updated indiscriminately. The retaining loss increases significantly in early training stages, indicating collateral damage to non-target knowledge. This validates that identifying conflicting parameters (Equation 9) is crucial for preserving retained knowledge while enabling efficient gradient propagation on relevant parameters.

w/ CAGrad (Figure 5b): Replacing our manifold-constrained optimization with CAGrad results in a higher forgetting loss plateau, indicating insufficient forgetting. CAGrad's approach does not explore the gradient manifold as effectively as our method, failing to find the optimal combination that balances both objectives.

w/ PCGrad (Figure 5c): Using PCGrad shows that while forgetting loss decreases, the retaining loss increases substantially. PCGrad's gradient projection strategy resolves conflicts by dropping conflicting components, which prevents effective learning on the retaining task. This demonstrates that our manifold-constrained formulation (Equation 11), which finds optimal combinations rather than projecting gradients, is superior for maintaining the forget-retain balance.

w/o Both (Figure 5d-e): Removing both components results in the worst training dynamics. The

Figure 5: Training dynamics (loss curves) for ablation study on LLaVA-1.5-7B. Each subplot shows forgetting and retaining losses over training iterations. (a) Without parameter identification, retaining loss increases, indicating collateral damage. (b-c) Alternative gradient methods (CAGrad, PCGrad) fail to achieve proper balance. (d) Removing both components leads to poor convergence. (e) Our full method achieves smooth convergence with effective forgetting and retention preservation.

forgetting loss plateaus at a higher value, and the retaining loss stabilizes early without further improvement. This confirms that neither component alone is sufficient—both partial parameter identification and manifold-constrained optimization are necessary for effective unlearning.

Our Method (Figure 5e): The full method shows smooth convergence for both losses, with forgetting loss steadily decreasing while retaining loss remains low and stable. This demonstrates that our two components work synergistically to enable principled conflict resolution.

E.4 Effect of α

Table 4 presents the comprehensive results across all α values. Several key observations emerge:

Forget-Retain Trade-off. The choice of α significantly impacts the forget-retain balance. At $\alpha = 0.0$, the model exhibits poor forgetting (56.67% classification accuracy on forget set) while achiev-ing high retention (58.18%), suggesting insufficient gradient adjustment for the forgetting task. Conversely, higher values like $\alpha = 0.85$ improve forgetting (48.33%) but degrade retention (43.55%), demonstrating the inherent trade-off between objectives.

Optimal Balance at $\alpha = 0.25$. Our selected value $\alpha = 0.25$ (used throughout the main paper) achieves superior balance: effective forgetting (41.66% classification accuracy, lowest among tested values) while maintaining reasonable retention (51.88%). This configuration yields the best ROUGE score on the retain set (0.318) and strong cloze accuracy (10.02%), indicating effective knowledge preservation on target concepts.

Real-world Generalization Stability. Notably, real-world performance remains relatively stable across all α values (72.06%-73.63% classification accuracy), with only minor variations in ROUGE scores (0.315-0.358). This demonstrates that our

Table 4: Performance across different rotation angle initializations α on Qwen2.5-VL-3B with MLLMU-Bench. Lower scores on forget set and higher scores on retain/real-world sets are better. Our method maintains stable real-world performance while $\alpha = 0.25$ achieves the best forget-retain balance.

α	Forget Set ($\downarrow$)			Retain Set ($\uparrow$)			Real-world Set ($\uparrow$)		
	Class Acc ($\downarrow$)	ROUGE Score ($\downarrow$)	Cloze Acc ($\downarrow$)	Class Acc ($\uparrow$)	ROUGE Score ($\uparrow$)	Cloze Acc ($\uparrow$)	Class Acc ($\uparrow$)	ROUGE Score ($\uparrow$)	Cloze Acc ($\uparrow$)
0.0	56.67	2.08	0.131	58.18	0.145	1.16	72.06	0.315	25.49
0.25	**41.66**	**2.083**	**0.263**	**51.88**	**0.318**	**10.02**	**73.36**	**0.348**	**21.56**
0.45	43.33	0.140	10.42	44.10	0.245	16.35	73.63	0.353	24.84
0.65	48.33	0.188	4.17	47.99	0.259	3.80	73.24	0.352	23.20
0.85	48.33	0.169	0.00	43.55	0.264	6.54	73.63	0.354	22.55
1.0	45.00	0.197	0.00	50.02	0.273	4.11	72.98	0.358	22.22

(a) $alpha = 0$ (b) $alpha = 0.25$ (c) $alpha = 0.45$

(d) $alpha = 0.65$ (e) $alpha = 0.85$ (f) $alpha = 1.0$

Figure 6: Loss curves for different rotation angle initializations α on Qwen2.5-VL-3B with MLLMU-Bench. Each subplot shows forgetting and retaining losses over training iterations. (a) $\alpha = 0$ shows poor forgetting and high retention. (b-f) Intermediate values ($\alpha \in [0.25, 0.85]$) achieve better balance, with $\alpha = 0.25$ (used in main paper) showing the best forget-retain balance. Extreme values ($\alpha = 0$ or $\alpha = 1.0$) degrade performance.

method's selective parameter identification successfully isolates unlearning to target knowledge without broadly degrading the model's general capabilities, regardless of the specific α initialization.

Sensitivity Analysis. Values in the moderate range ($\alpha \in [0.25, 0.65]$) exhibit more consistent performance across metrics compared to extreme values ($\alpha = 0.0$ or $\alpha = 1.0$). This suggests that intermediate initializations provide better starting points for the optimization to converge to effective gradient combinations.

Based on this analysis, we recommend $\alpha = 0.25$ as the default initialization, which consistently achieves the best forget-retain balance while maintaining strong real-world generalization. For applications requiring more aggressive forgetting at the cost of some retention, higher values ($\alpha \in [0.45, 0.65]$) may be considered. The stability of real-world performance across all tested values confirms the robustness of our approach.

E.4.1 Loss Curve Analysis

We visualize the loss curves for different rotation angle initializations α on Qwen2.5-VL-3B with MLLMU-Bench. Each subplot shows forgetting and retaining losses over training iterations. (a) $\alpha = 0$ shows poor forgetting and high retention. (b-f) Intermediate values ($\alpha \in [0.25, 0.85]$) achieve better balance, with $\alpha = 0.25$ (used in main paper) showing the best forget-retain balance. Extreme values ($\alpha = 0$ or $\alpha = 1.0$) degrade performance.

F Cost Analysis of EASE

To assess the computational impact of our method, we report wall-clock time, memory usage, and forward/backward pass counts on Qwen2.5-VL-7B with MLLMU-Bench in Table 5, the batch size is set to 1 and training epoch is 1.

Table 5: Computation, memory, and time cost for different unlearning methods on Qwen-7B.

Method	Time (min)	Peak alloc (GB)	Peak reserved (GB)
NPO	0.84	23.58	27.28
MLLMU	7.22	20.51	23.24
KL-Min	7.30	22.73	44.89
GA-Diff	6.05	20.51	23.80
Our-Overlap	7.40	7.34	16.70

Compared to prior unlearning methods (MLLMU, KL-Min, GA-Diff), Our-Overlap attains comparable wall-clock time while substantially reducing peak reserved memory (16.70 GB vs. up to 44.89 GB for KL-Min). The increased number of forward and backward passes reflects the additional optimization steps used to refine gradient directions, but this cost remains practical given the memory savings and improved forget–retain performance. Overall, these results demonstrate that MCGDO offers a favorable trade-off between computational efficiency and unlearning quality, making it suitable for deployment on large MLLMs.

Retaining Performance for VQA Task (LLAVA-1.5-7B)

Person Profile

Description:

Liam Vanhoutte, born in Gent, Belgium, is a civil engineer currently residing in Stuttgart, Germany. Standing at 180 cm tall, he earned his degree from KU Leuven and has an annual salary of $85,000. His father Lucas is an architect, and his mother Iris is a high school teacher. In his free time, Liam enjoys hiking in the Black Forest, indulging in artisanal Belgian chocolate, and spending time with his cat, Felix.

Question: Based on their background, where does this individual likely reside?
GT: The individual likely resides in San Francisco, USA.
Grad_Diff:
This individual enjoys hiking in the mountains.
KL_Min:
This individual is an avid hiker.
NPO:
TThis individual is an avid hiker.
MMUnlearner:
This individual enjoys hiking.
Ours:
This individual enjoys hiking.
