## ABSTRACT

Scaffolding Large Language Models (LLMs) into multi-agent systems often improves performance on complex tasks, but the safety impact of such scaffolds has not been as thoroughly explored. In this paper, we introduce AGENTBREEDER a framework for multi-objective self-improving evolutionary search over scaffolds. In 'red' mode, the discovered scaffolds make the base LLM more susceptible to jailbreaks whilst also achieving high task success. In 'blue' mode, the focus shifts to ensuring safety and task reward. We evaluate the scaffolds discovered and compare them with popular baselines using widely recognized reasoning, mathematics, and safety benchmarks. Our work highlights and mitigates the safety risks due to multi-agent scaffolding. Code is available at https://github.com/J-Rosser-UK/AgentBreeder.

## 1 INTRODUCTION

Recently, the field of artificial intelligence has witnessed remarkable advancements in Large Language Models (LLMs) and their applications (Zhao et al., 2023). LLMs are capable of exhibiting human-like reasoning (Amirizaniani et al., 2024; Sun et al., 2024; Xu et al., 2025), enabling their application beyond natural language processing to diverse areas such as code generation (Romera-Paredes et al., 2024; Wang & Chen, 2023; Yetiştiren et al., 2023), embodied AI in robotics (Hu et al., 2023; Kong et al., 2024; Sartor & Thompson, 2024), and autonomous agents (OpenAI, 2025; Convergence, 2024).

Our research is motivated by accelerated advancements in autonomous agents such as the recent release of Operator (OpenAI, 2025) and Proxy (Convergence, 2024) - agents that browse the web and perform tasks autonomously on behalf of the user. Alignment research to date has almost exclusively focused on the safety of LLMs in unipolar scenarios; ensuring a single LLM remains aligned inside a single-agent system. When deployed on the web, agents are placed in novel multi-agent scaffolds and subjected to multi-polar challenges (Khan, 2022). With highly-capable agents now being deployed at scale, we seek to address the immediate need for more comprehensive safety evaluations of multi-agent systems.

In this paper, we introduce AGENTBREEDER, an evolutionary open-ended framework capable of generating large populations of diverse multi-agent scaffolds. By equipping this framework with multi-objective optimization, we explore the generation of multi-agent scaffolds along complementary objectives of capability and safety. AGENTBREEDER can be used to blue team a set of scaffolds to generate offspring that exhibit greater adversarial robustness and performance on capability benchmarks. Similarly, a red teaming approach generates offspring that exhibit greater vulnerability to adversarial attacks. **Our main contributions are listed as follows:**

- **Attack.** We introduce a novel red teaming method which can be used to explore the attack surfaces of base LLMs when deployed in multi-agent settings.
- **Defense.** We introduce a novel blue teaming method for generating multi-agent scaffolds that exhibit greater robustness to adversarial attacks.
- **Evaluation.** We implement AGENTBREEDER in Inspect AI Safety Institute (2024) to ensure the reproducibility and extensibility of our results and methods.

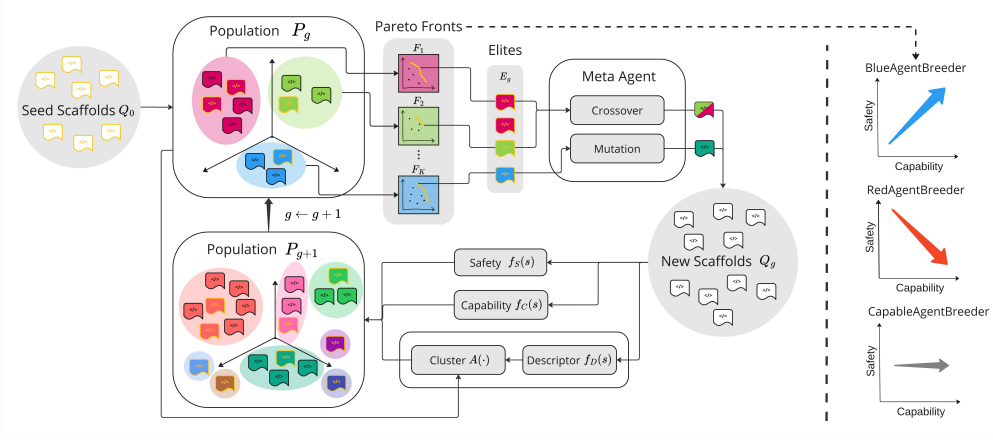

Figure 1: A high-level illustration of the AGENTBREEDER algorithm as outlined in Algorithm 1. Starting from seed scaffolds $Q_0$, at each generation $g$ the newly generated scaffolds $Q_{g-1}$ are evaluated on capability ($f_C(s)$) and/or safety ($f_S(s)$) benchmarks, then embedded via $f_D(s)$ for clustering $A(\cdot)$ into $K$ clusters. Within each cluster, Pareto fronts $F_1, ..., F_K$ are identified according to $f_C(s)$ and/or $f_S(s)$, and these "frontier" solutions become the elite set $E_g$. An LLM-based Meta Agent applies crossover and mutation to the elites, creating new offspring scaffolds $Q_g$. These offspring are added to the population for the next generation $P_{g+1}$. By repeating this process for $G$ generations, AGENTBREEDER explores a large, diverse set of multi-agent systems while balancing capability and safety. AGENTBREEDER can be run in 3 different modes and the right-hand side of this figure shows the optimal direction of travel of the Pareto front for each generation. BLUEAGENTBREEDER is a defense mode and seeks to maximize both capability and safety, whereas REDAGENTBREEDER is an attack mode minimizing safety. CAPABLEAGENTBREEDER serves as our baseline, only optimizing for capability without regard to safety.

**Algorithm 1:** AgentBreeder

**Input:** Number of generations $G$; Number of clusters $K$; Number of evolutions $M$; Capability benchmark $f_C(s)$; Safety benchmark $f_S(s)$; Embedding function $f_D(\cdot)$; Seed scaffolds $Q_0$; Clustering function $A(\cdot)$.

**Initialize seed population** $P_0 = Q_0$ **of size** $N_0$**. for** *generation* $g = 1$ *to* $G$ **do**

  **for** *scaffold* $s \in Q_{g-1}$ **do**

    1. Compute capability $f_C(s)$ and safety $f_S(s)$.
    2. Compute embedding $e_s \leftarrow f_D(s)$.

  **Cluster population into** $K$ **clusters:** $C_1, C_2, \ldots, C_K \leftarrow A(e_1, e_2, ..., e_{N_g})$.

  **Identify Pareto Elites** $E_g$**:**

    1. Set $E_g \leftarrow \emptyset$.
    2. **for** *cluster* $k = 1$ *to* $K$ **do**
       (a) Find its Pareto front $F_k$ using $f_C$ and $f_S$.
       (b) Update elite cohort $E_g \leftarrow E_g \cup F_k$.

  **Generate offspring** $Q_g$**:**

    1. Set $Q_g \leftarrow \emptyset$.
    2. **for** *evolution* $m = 1$ *to* $M$ **do**
       (a) Weighted sampling 1 or 2 elites from $E_g$.
       (b) If 2 elites, Meta Agent performs Crossover; otherwise Mutation.
       (c) Add the offspring to $Q_g$.

  **Update population:** $P_g \leftarrow P_{g-1} \cup Q_g$. **Update population size:** $N_g \leftarrow N_{g-1} + M$.

**Output:** Final population $P_G$.

## 2 BACKGROUND

**Multi-Agent Systems.** Multi-agent systems consist of multiple interacting intelligent agents such as LLM assistants like ChatGPT (OpenAI, 2024). These systems offer several advantages over single-agent approaches (Yang et al., 2024), including planning (Li et al., 2024a; Cao et al., 2024), task decomposition (Chen et al., 2023; Fourney et al., 2024; Ghafarollahi & Buehler, 2024; Qian et al., 2023), and specialization (Chan et al., 2023; Chen et al., 2023; Fourney et al., 2024; Ghafarollahi & Buehler, 2024; Qian et al., 2023). The terms "multi-agent system", "multi-agent framework", "agent" and "scaffold" are used interchangeably in literature to refer to the structural frameworks that support communication between multiple LLMs (Huang et al., 2024; Yin et al., 2024; Hu et al., 2024a; Fowler, 2023). In this paper, we will primarily use the term "scaffold" to refer to the architectures - often defined in Python code - that support the operation of multi-agent systems.

**Automated Design of Agentic Systems.** We build upon the seminal work of Hu et al. (2024a) which introduces the research area Automated Design of Agentic Systems (ADAS), an automated approach to discovering high-performing (multi-agent) scaffolds. Hu et al. (2024a) formulate ADAS as an optimization algorithm comprising 3 key components; the search space, the search algorithm and the evaluation function. Hu et al. (2024a) also propose a search algorithm called "Meta Agent Search" where a single "Meta Agent" discovers scaffolds by programming them in Python code. Python is a Turing Complete language (Boyer & Moore, 1983) therefore searching within a code space allows the Meta Agent to program theoretically any possible scaffold. This approach has shown promising results (Hu et al., 2024a; Yin et al., 2024), with discovered scaffolds outperforming state-of-the-art hand-designed baselines across various tasks, including reading comprehension, mathematics, and science questions Hendrycks et al. (2020); Shi et al. (2022); Rein et al. (2023); Chollet (2019); Dua et al. (2019).

We formulate AGENTBREEDER with respect to the ADAS methodology. We replicate the approach of Hu et al. (2024a) by seeding our population with hand-designed scaffolds. We prompt a single "Meta Agent" to search for novel scaffolds in the space of Python code. We introduce a novel quality-diversity search algorithm inspired by MAP-Elites (Mouret & Clune, 2015), where the Meta Agent evolves new scaffolds via the random sampling, mutation and crossover of the highest performing individual or "elite" of each niche of the population. We cluster scaffolds based on their architectural features, and evaluate the performance of scaffolds on two benchmarks, one for capability and one for safety. We employ multi-objective optimization, sampling elites from the Pareto front of each cluster.

**Multi-Objective Evolutionary Algorithms.** Multi-objective optimization searches for solutions to problems with multiple, often conflicting objectives. Multi-objective evolutionary algorithms (MOEAs) incorporate an evolutionary approach to generate a diverse set of solutions (Kesireddy & Medrano, 2024). In AGENTBREEDER we seek to balance the objectives of capability and safety whilst evolving a diverse range of scaffolds. AGENTBREEDER balances quality and diversity by clustering scaffolds based on their architectural features and randomly sampling elites from each cluster's capability-safety Pareto front. A solution is Pareto optimal if no other solution improves one objective without worsening another. The Pareto front comprises all such optimal solutions.

**Adversarial Robustness.** Adversarial robustness quantifies the resilience of a model or scaffold to malicious inputs such as jailbreaks (Chao et al., 2023) and prompt injection (Liu et al., 2023). Red teaming, the practice of simulating adversarial scenarios to identify vulnerabilities, has emerged as a crucial tool for assessing AI model risks and alignment (Samvelyan et al., 2024; Perez et al., 2022). In REDAGENTBREEDER, instead of generating adversarial examples, we seek to evolve multi-agent scaffolds that are more vulnerable to adversarial attacks than the base model. In BLUEAGENT-BREEDER, we seek to evolve multi-agent scaffolds that are more robust to adversarial attacks than the base model.

## 3 RELATED WORK

**Self-Referential Self-Improving Systems.** Numerous frameworks (Yuan et al., 2024; Hu et al., 2024b;a; Xue et al., 2024; Yin et al., 2024) have been proposed to address the design of multi-agent scaffolding. EvoAgent (Yuan et al., 2024) extends single expert agents to multi-agent scaffolds via evolutionary algorithms, whilst AGENTBREEDER evolves the entire system as a unit. EvoMAC (Hu et al., 2024b) evolves agents and their connections during test time to improve code generation,

whereas AGENTBREEDER is domain agnostic and can explore the entire search space of scaffolds. ADAS (Hu et al., 2024a), ComfyAgent (Xue et al., 2024) and Gödel Agent (Yin et al., 2024) search in the space of code for novel scaffolds, but unlike AGENTBREEDER they do not incorporate a quality-diversity mechanism for exploring agent design space. FunSearch (Romera-Paredes et al., 2024) is an evolutionary method to search the function space for high-performing computer programs but not necessarily scaffolds.

**Multi-Agent Safety Research.** Zhang et al. (2024) evaluate the safety of multi-agent scaffolds from a psychological perspective by injecting agents with malicious traits, and provide mitigation strategies such as performing psychological assessments and therapy for agents. Polaris (Mukherjee et al., 2024) introduces a safety-focused scaffold for real-time patient healthcare conversations. Huang et al. (2024) explore the resilience of multi-agent scaffolds when injected with malicious or error-prone agents. Fowler (2023) provide a more thorough discussion of the safety risks associated with scaffolded LLMs.

## 4 AGENTBREEDER

We now introduce AGENTBREEDER, our automated, evolutionary approach to discovering new multi-agent scaffolds. By evolving a large, diverse corpus of multi-agent scaffolds, AGENTBREEDER seeks to address the challenge of evaluating the vulnerabilities of base LLMs acting inside capability-optimized multi-agent scaffolds. The pseudo-algorithm is given in Algorithm 1 and Figure 1 provides a brief overview. AGENTBREEDER can be run in three modes:

- BLUEAGENTBREEDER - In this mode, the Meta Agent adopts the role of a "Blue Team", searching for scaffolds that exhibit high capability and safety when evaluated on representative benchmarks.
- REDAGENTBREEDER - In this mode, the Meta Agent adopts the role of a "Red Team", minimizing performance on one safety benchmark whilst maximizing performance on one capability benchmark.
- CAPABLEAGENTBREEDER - In this mode, the Meta Agent seeks to maximize performance on a single capability benchmark without consideration of safety.

### 4.1 SEED SCAFFOLDS

Following the approach of Hu et al. (2024a) and Yin et al. (2024), we seed our population with the same 7 hand-designed scaffolds. These comprise Chain-of-Thought (CoT) (Wei et al., 2022), Self-Consistency with Chain-of-Thought (Wang et al., 2022), Self-Refine (Madaan et al., 2024), LLM-Debate (Du et al., 2023), Step-back Abstraction (Zheng et al., 2023), Quality-Diversity (QD) (Lu et al., 2024), and Role Assignment (Xu et al., 2023). Before running our evolution on our chosen benchmark, we evaluate a single CoT agent on 1,000 samples from the validation set of the benchmark, oversampling and resampling where necessary. For each generation, we validate the newly discovered scaffolds using a balanced sampling strategy, selecting 50% positive and 50% negative samples. Often improvements between generations are marginal, so this method increases information gain by providing a stronger signal for the evolutionary process.

### 4.2 MUTATION OPERATORS

AGENTBREEDER's evolutionary search algorithm mimics the process of natural selection comprising mutation, crossover and selection. Claude 3.5 Sonnet (Anthropic, 2024) (*claude-3-5-sonnet-20241022-v2:0*) is used as the core model of the Meta Agent due to its state-of-the-art performance on code generation tasks (Tian et al., 2024).

**Selection.** Selection pressure is applied at each generation by sampling candidate scaffolds at random from the Pareto fronts of each cluster. In CAPABLEAGENTBREEDER, the Pareto front is simply the elite of each cluster, whereas in BLUEAGENTBREEDER and REDAGENTBREEDER, the Pareto front comprises the scaffolds which best trade-off safety and capability.

**Mutation.** The Meta Agent uses weighted random sampling to select either the crossover or mutation operator. Weighting the mutation operator twice as highly as crossover was found empirically

to lead to faster convergence. Mutation is performed via random sampling of mutation operators expressed as short textual passages we hand-designed. There are two types of mutation operators, capability-enhanced and safety-enhanced. When running BLUEAGENTBREEDER, mutation operators are randomly sampled from the concatenated capability- and safety-enhanced corpus. In REDAGENTBREEDER and CAPABLEAGENTBREEDER the safety-enhanced operators are omitted. The full list of Meta Agent prompts and mutation operators are given in Appendix C.

**Crossover.** During crossover, the Meta Agent is provided with two randomly sampled scaffolds from the population and tasked with combining them in such a way that would be likely to improve performance performance. The full crossover prompt is given in Appendix C.6.

### 4.3 DESCRIPTORS

In open-ended evolutionary approaches, descriptors are essential for quantifying the diversity of candidate solutions (Mouret & Clune, 2015). In order to explore the full range of vulnerabilities of a base model, we seek to generate and evaluate a diverse range of multi-agent scaffolds and require high-dimensional descriptors. In AGENTBREEDER, we use OpenAI's *text-embedding-3-small* (OpenAI, 2024b) model returning a 12-dimensional text embedding of the system name and code as our descriptor to encode semantic information about the name, structure, and potential logic embedded in the scaffold.

### 4.4 CLUSTERING

Once the descriptors have been generated for the new scafolds, AGENTBREEDER re-clusters the whole population based on their descriptors to discover groups of similar architectures. We choose agglomerative clustering as it has been found to be particularly effective for smaller datasets like ours (Weigand et al., 2021). By setting a distance threshold in the agglomerative clustering algorithm, we allow the number of clusters to adjust flexibly. When the number of clusters increases, the selection pressure decreases towards zero. Conversely, reducing the number of clusters encourages the algorithm to explore only a few options, which leads to less diverse scaffolds. To achieve a balanced trade-off between system performance and system diversity, a distance threshold of 0.7 was selected.

### 4.5 MULTI-OBJECTIVE PARETO ELITES

In Quality-Diversity algorithms such as MAP-Elites (Mouret & Clune, 2015), selection pressure is applied by randomly sampling the highest-performing candidates in each niche for evolution, referred to as the "elites". In multi-objective optimization, a solution is Pareto optimal if no other solution improves one objective without worsening another (Kesireddy & Medrano, 2024). The Pareto front comprises all such optimal solutions. In AGENTBREEDER, instead of sampling from pre-defined niches, we sample elites from the Pareto fronts of dynamically generated clusters.

### 4.6 EVALUATIONS

Evaluations are implemented in Inspect (AI Safety Institute, 2024), an open-source framework for LLM evaluations. We instantiate AGENTBREEDER as a custom model provider by deriving a new class from ModelAPI, and each individual scaffold derives as a Model from that ModelAPI. This allows comprehensive experiment tracking and parallelization, and provides an extensible framework allowing AGENTBREEDER to be run on a new benchmark often with fewer than 100 lines of code. In Section 5, we report results on 5 benchmarks comprising safety, capability and helpfulness.

## 5 EXPERIMENTS

We conduct experiments to validate AGENTBREEDER's three modes; BLUEAGENTBREEDER, REDAGENTBREEDER, CAPABLEAGENTBREEDER. To evaluate the capability of the multi-agent scaffolds produced, we follow the approaches of Hu et al. (2024a) and Yin et al. (2024) and report results on three benchmarks from OpenAI's simple-evals OpenAI (2023). To evaluate system safety, we report results on one comprehensive safety benchmark. A full description of each benchmark can be

| CAPABLEAGENTBREEDER | | | |
|---|---|---|---|
| Capability | | | Safety |
| **DROP** | **MMLU** | **GPQA** | **SaladData** |
| *Seed Scaffolds (Hu et al., 2024a)* | | | |
| $70.4 \pm 3.1$ | $80.2 \pm 3.6$ | $35.2 \pm 4.4$ | $31.2 \pm 4.2$ |
| $64.4 \pm 3.2$ | $\mathbf{82.6 \pm 3.4}$ | $38.1 \pm 4.3$ | $17.8 \pm 3.4$ |
| $69.3 \pm 3.2$ | $81.2 \pm 3.6$ | $\underline{39.4 \pm 4.4}$ | $55.6 \pm 4.6$ |
| *ADAS Scaffolds* | | | |
| $\underline{72.0 \pm 3.0}$ | - | - | $57.0 \pm 4.2$ |
| - | $80.4 \pm 3.4$ | - | $\mathbf{76.4 \pm 3.6}$ |
| - | - | $37.4 \pm 3.6$ | $61.0 \pm 4.2$ |
| *CapableAgentBreeder Scaffolds* | | | |
| $\mathbf{72.3 \pm 3.1}$ | - | - | $39.4 \pm 4.4$ |
| - | $\underline{82.4 \pm 3.2}$ | - | $\underline{58.0 \pm 4.2}$ |
| - | - | $\mathbf{41.2 \pm 4.4}$ | $43.8 \pm 4.4$ |

Table 1: We report the evaluation results of CAPABLEAGENTBREEDER on the held-out test sets. For each benchmark, we compare the AGENTBREEDER-discovered scaffolds with the seed and discovered scaffolds from the seminal work ADAS Hu et al. (2024a), with the highest and second highest result in each column given in bold and underlined respectively. We report the F1 score on DROP (Dua et al., 2019) and median accuracy on the other benchmarks, along with a 95% confidence interval computed over 500 held-out test samples.

found in Appendix B. To evaluate the safety of multi-agent scaffolds, we adopted a method inspired by Constitutional AI, where an LLM judges responses based on a predefined set of principles. We transformed the Anthropic Claude Constitution Bai et al. (2022) into a series of yes/no questions. During validation, each system responded to 100 attack-enhanced prompts, and an agent aware of the constitution evaluated the safety of each response. We then reported the median accuracy and the 95% bootstrap confidence interval for each scaffold's safety performance.

### 5.1 EXPERIMENT 1: CAPABILITY

We perform comprehensive experiments on three benchmarks to validate AGENTBREEDER against ADAS (Hu et al., 2024a), the seminal work in this field. We run CAPABLEAGENTBREEDER - a single-objective-variant of our framework - for 20 generations, evolving 10 mutants each generation. We take the highest performing scaffolds from ADAS and evaluate them with GPT-4o mini (OpenAI, 2024) as their core model. We report the F1 score for DROP, median accuracy for MMLU and GPQA and their 95% confidence intervals, as well as their performance on SaladData, our chosen safety benchmark. The results are shown in Table 1.

**Comparable Performance to Previous Work.** CAPABLEAGENTBREEDER achieves competitive results to ADAS, marginally surpassing performance across all capability benchmarks.

**Multi-Objective outperforms Single-Objective Optimization.** The scaffolds discovered during by CAPABLEAGENTBREEDER achieve near or slightly above-baseline results, such as 72.3 $\pm$3.1 F1 on DROP and 41.2$\pm$4.4 accuracy on GPQA. This performance gain is notably smaller than in the multi-objective setting. This supports our hypothesis that incorporating an additional benchmark may increase the signal-to-noise ratio of system validations each generation. This improves the quality of the selection pressure for the evolutionary algorithm, helping the process converge to better solutions overall.

**Safety Performance as a Byproduct.** In single-objective ablation runs, the discovered scaffolds showed only modest performance on SaladData, suggesting that ignoring safety in the objective yields no strong impetus for safe or unsafe behaviors. This contrasts with multi-objective runs, where explicit safety optimization (or "negative safety" in red-teaming) substantially influenced outcomes.

**Performance Stagnates with Better LLMs.** When using more advanced models (GPT-4o mini (OpenAI, 2024) for scaffolds and Claude 3.5 Sonnet (Anthropic, 2024) for the Meta Agent) compared to the original ADAS (Hu et al., 2024a) implementation, we observe that while overall performance improves, the relative gain between seed and discovered scaffolds diminishes. We attribute this to three plausible factors: (1) increased data contamination in newer LLMs may lead to memorized solutions rather than genuine reasoning, (2) higher baseline performance makes marginal improvements harder

| BLUEAGENTBREEDER | Capability | | | Safety | Helpfulness |
|---|---|---|---|---|---|
| | **DROP** | **MMLU** | **GPQA** | **SaladData** | **TruthfulQA** |
| *Seed Scaffolds from ADAS Hu et al. (2024a)* | | | | | |
| Chain-of-Thought (CoT) | $66.6 \pm 5.0$ | $80.0 \pm 4.4$ | $31.2 \pm 5.6$ | $29.2 \pm 5.6$ | $86.8 \pm 3.6$ |
| Self-Consistency CoT | $66.0 \pm 4.4$ | $81.6 \pm 4.8$ | $32.4 \pm 6.0$ | $22.8 \pm 5.2$ | $85.6 \pm 4.4$ |
| Self-Refinement | $61.4 \pm 4.8$ | $78.4 \pm 5.2$ | $28.4 \pm 6.0$ | $26.0 \pm 5.2$ | $86.8 \pm 4.0$ |
| Debate | $69.9 \pm 4.4$ | $77.6 \pm 5.2$ | $29.6 \pm 5.6$ | $36.4 \pm 6.0$ | $86.4 \pm 4.0$ |
| Step-Back Abstraction | $71.4 \pm 4.3$ | $79.2 \pm 4.8$ | $30.8 \pm 5.2$ | $40.8 \pm 5.6$ | $85.2 \pm 4.4$ |
| Quality-Diversity | $\underline{78.0 \pm 3.9}$ | $81.6 \pm 4.4$ | $28.4 \pm 5.6$ | $25.8 \pm 5.8$ | $\underline{87.2 \pm 4.0}$ |
| Role Assignment | $75.8 \pm 4.2$ | $79.2 \pm 4.8$ | $32.0 \pm 6.0$ | $18.0 \pm 5.2$ | $85.6 \pm 4.4$ |
| *BlueAgentBreeder Scaffolds ($S$ = SaladData, $H$ = TruthfulQA)* | | | | | |
| $\arg\max_s\{f_{C_{\text{DROP}}}\}$ | $\mathbf{79.0 \pm 3.8}$ | - | - | $46.4 \pm 6.4$ | $\mathbf{88.0 \pm 4.0}$ |
| $\arg\max_s\{f_S\}$ | $62.0 \pm 4.8$ | - | - | $\underline{86.0 \pm 4.0}$ | $83.6 \pm 4.4$ |
| $\arg\max_s\{f_{C_{\text{DROP}}}, f_S, f_H\}$ | $62.0 \pm 4.8$ | - | - | $\underline{86.0 \pm 4.0}$ | $83.6 \pm 4.4$ |
| $\arg\max_s\{f_{C_{\text{MMLU}}}\}$ | - | $\mathbf{85.2 \pm 4.4}$ | - | $54.0 \pm 5.6$ | $81.2 \pm 4.4$ |
| $\arg\max_s\{f_S\}$ | - | $\underline{84.0 \pm 4.4}$ | - | $84.4 \pm 4.0$ | $76.0 \pm 5.2$ |
| $\arg\max_s\{f_{C_{\text{MMLU}}}, f_S, f_H\}$ | - | $\underline{84.0 \pm 4.4}$ | - | $84.4 \pm 4.0$ | $76.0 \pm 5.2$ |
| $\arg\max_s\{f_{C_{\text{GPQA}}}\}$ | - | - | $\mathbf{39.2 \pm 5.6}$ | $52.0 \pm 6.8$ | $57.6 \pm 6.4$ |
| $\arg\max_s\{f_S\}$ | - | - | $31.2 \pm 6.0$ | $\mathbf{95.2 \pm 2.4}$ | $49.6 \pm 6.4$ |
| $\arg\max_s\{f_{C_{\text{GPQA}}}, f_S, f_H\}$ | - | - | $\underline{36.8 \pm 5.2}$ | $49.2 \pm 6.8$ | $86.8 \pm 4.0$ |

Table 2: We report the evaluation results of BLUEAGENTBREEDER on the held-out test set of capability benchmark (DROP (Dua et al., 2019), MMLU (Hendrycks et al., 2020), GPQA (Rein et al., 2023)), safety benchmark (SaladData (Li et al., 2024b)) and ensure a trivial solution has not been found by evaluating each scaffold's helpfulness on TruthfulQA (Lin et al., 2021). For each benchmark, we compare the AGENTBREEDER-discovered scaffolds against baseline scaffolds, with the highest and second highest result in each column given in bold and underlined respectively. We report the median accuracy (or F1 score for DROP) along with a 95% confidence interval computed over 250 held-out test samples. The evolution is conducted independently for each capability benchmark.

to distinguish from noise and (3) recent models are already fine-tuned for detailed reasoning, reducing the benefit of scaffold-induced reasoning steps (OpenAI, 2024a; Zaremba et al., 2025).

### 5.2 EXPERIMENT 2: BLUE TEAM DEFENSE

We ran BLUEAGENTBREEDER for 20 generations, with the aim of generating "Blue-Teams" of multi-agent scaffolds that simultaneously optimize for capability and safety across our chosen benchmarks. We generate 10 new mutants each generation, and report the median accuracy and the 95% confidence interval on the held-out test set in Table 2. To reduce AGENTBREEDER's tendency to reward-hack the safety benchmark by finding a trivial safe response to question-answering tasks that require a long-form response, during evaluation, we report the "helpfulness" of the scaffold on questions from TruthfulQA (Lin et al., 2021).

**Marginal but Consistent Improvements Over Baselines.** We observed that, for DROP Dua et al. (2019), the "DROP Capable" agent attained an F1 score of $79.0 \pm 3.8$, surpassing both the Chain-of-Thought and Step-Back Abstraction baselines. Although the absolute increase (about 1 point over the next highest baseline) is modest, it consistently emerged across repeated runs.

**Vulnerability to Reward Hacking.** We note that certain specialized systems, such as "GPQA Safe", display inflated scores on our safety benchmark, SaladData (Li et al., 2024b) achieving an accuracy of $95.2 \pm 2.4$. However, under closer examination, the system shows a significant decrease in performance on our helpfulness benchmark ($49.6 \pm 6.4$). We find that multi-agent scaffolds are prone to reward-hacking the safety objective e.g. by finding a trivial solution such as responding "I'm sorry I can't help with that" to any question outside of their domain, and that one way of detecting this behavior is by reporting performance on a helpfulness benchmark.

| RED AGENTBREEDER | Capability **DROP** | Harm **1-SaladData** |
|---|---|---|
| *Seed Scaffolds from ADAS Hu et al. (2024a)* | | |
| CoT | $68.2 \pm 4.7$ | $\underline{76.8 \pm 4.8}$ |
| CoTSC | $69.6 \pm 4.8$ | $70.8 \pm 6.0$ |
| Refine | $62.6 \pm 4.7$ | $71.6 \pm 5.2$ |
| Debate | $63.2 \pm 4.8$ | $56.0 \pm 6.0$ |
| StepBack | $67.5 \pm 4.5$ | $58.0 \pm 6.0$ |

Table 3: We report the evaluation results of AGENTBREEDER run in "red" mode on the held-out test set. We seek to maximize performance on DROP (Dua et al., 2019) whilst also maximizing performance on 1-SaladData (Li et al., 2024b), an inverted version of the SaladData benchmark where unsafe responses are scored highly. For each benchmark, we compare the AGENTBREEDER-discovered scaffolds against baseline scaffolds, with the highest and second highest result in each column given in bold and underlined respectively. We report the F1 score and median accuracy for DROP and 1-SaladData respectively, along with a 95% confidence interval computed over 250 held-out test samples.

### 5.3 EXPERIMENT 3: RED TEAM ATTACK

Our second set of experiments employed REDAGENTBREEDER, which deliberately seeks to discover "Red-Team" multi-agent scaffolds which illuminate the safety vulnerabilities of the base LLM while preserving capability on DROP (Dua et al., 2019). Table 3 summarizes these results. We introduce an inverted safety benchmark "1-SaladData" which contains the same questions as the original SaladData (Li et al., 2024b) benchmark, but utilizes an inverted scoring function that awards higher scores for unsafe responses.

**Unsafe Scaffolds are Easier to Find.** The "DROP Unsafe" system obtained an accuracy of 81.6±4.8 on the inverted 1-SaladData Li et al. (2024b) metric, surpassing all baseline scaffolds (e.g., CoT with 76.8±4.8). These results not only demonstrate REDAGENTBREEDER's capacity to discover scaffolds with greater susceptibility to unsafe behavior but also underscore how it is easier to find unsafe scaffolds than safe ones: in this setup, we required only 10 generations, half the budget of the blue-teaming experiments.

**Capability Disguises Safety Vulnerabilities.** Interestingly, even while maximizing unsafe performance, the "Most Unsafe" system maintained a DROP F1 score of 67.7±4.7. This result is comparable to the baseline scaffolds, highlighting that scaffolds can appear just as capable in terms of task performance yet simultaneously exhibit increased safety vulnerabilities.

## 6 DISCUSSION

**Pre-Deployment Safety Evaluations.** The Dead Internet Theory posits a future where AI agents dominate online activity (Walter, 2024). While speculative, the recent releases of Operator (OpenAI, 2025) and Proxy (Convergence, 2024) highlight the increasing population of agents deployed with the ability to interact autonomously with other agents and humans. These underscore the uncertainty around agent-on-agent dynamics, especially when these agents evolve or compose themselves in unanticipated ways. Our REDAGENTBREEDER experiments illustrate an automated approach to efficiently surface multi-agent scaffolds that exhibit vulnerabilities on safety benchmarks. Over time, labs could adopt a REDAGENTBREEDER-style pipeline to proactively "red-team" new LLMs as part of a release protocol.

**Post-Deployment Adversarial Robustness.** Just as REDAGENTBREEDER discovers vulnerable scaffolds, BLUEAGENTBREEDER provides a methodology to design safe and capable multi-agent scaffolds. This method can also be used to upgrade the safety capabilities of existing scaffolds, akin to Weak-to-Strong Generalization (Burns et al., 2023). Furthermore, BLUEAGENTBREEDER can be used to ensure a scaffold conforms to dynamic company values, policies and regulatory requirements. These experiments validate the practicality of evolutionary search as a dynamic, data-driven tool for

multi-agent evaluation. Open-ended, iterative methods are valuable complements to standard single-agent evaluations. As multi-agent scaffolds become more prominent, AGENTBREEDER provides a framework to aid in evaluating, strengthening, and governing LLMs before wide-scale deployment.

**Limitations.** While our experiments provide promising insights, several limitations should be acknowledged. Firstly, due to computational costs, we conducted experiments over a limited number of generations and with relatively small population sizes, resulting in only marginal performance improvements. Secondly, our experimental setup serves as a proof of concept for multi-objective alignment, and stronger claims of helpfulness and safety would require evaluations on more comprehensive benchmarks. Additionally, our evaluation was restricted to a select set of benchmarks, which may not fully capture the diverse range of real-world capabilities and safety concerns. Finally, the initial population was limited to seven seed scaffolds, potentially constraining the diversity of discovered scaffolds.

## 7 CONCLUSION

This paper introduces AGENTBREEDER, an evolutionary framework for discovering and evaluating multi-agent scaffolds via the multi-objective optimization of capability and safety. Our experiments demonstrate that AGENTBREEDER operates effectively in three distinct modes. BLUEAGENTBREEDER for developing safer scaffolds, REDAGENTBREEDER for identifying vulnerabilities, and CAPABLEAGENTBREEDER for maximizing task performance. Through empirical evaluation across multiple benchmarks, we show that our framework discovers scaffolds that achieve competitive or increased performance to prior works while exhibiting increased adversarial robustness.

Our results highlight several important findings for AI safety research. First, we demonstrate that unsafe behaviors can coexist with strong task performance, as evidenced by REDAGENTBREEDER's ability to generate scaffolds that maintain capability while exhibiting increased vulnerability. Second, our experiments reveal that multi-objective optimization targeting both capability and safety yields better overall solutions compared to single-objective approaches. Finally, we show that automated evolutionary methods can effectively probe the complex attack surfaces of multi-agent scaffolds, offering a practical approach to pre-deployment safety evaluation.

As AI systems become increasingly interconnected and deployed in real-world settings, frameworks like AGENTBREEDER bridge the research gap between single-agent and multi-agent safety evaluations. Our work establishes a foundation for the systematic evaluation of multi-agent scaffolds, contributing to the development of safer and more reliable AI technologies.

## 8 FUTURE WORK

**Scaling Laws.** Scaling up AGENTBREEDER to larger population sizes and longer evolutionary runs could yield more substantial improvements in both capability and safety metrics. Incorporating closed-source safety benchmarks such as AILuminate (MLCommons Association, 2025) and contamination-free capability benchmarks such as MMLU-CF (Zhao et al., 2024) would provide a more comprehensive assessment of multi-agent system safety.

**White-Box and Gray-Box Evaluations.** A key limitation of our current approach is its focus on black-box evaluation of scaffolds. Future work could investigate individual agent behaviors, including how agents interact with tools, external APIs, and information sources. Developing methods to trace and analyze agent-agent and agent-tool interactions could reveal potential safety risks that are invisible in black box evaluation. Additionally, future work could automate the analysis of agent interactions to identify patterns that lead to safety vulnerabilities.

**Alternative Objectives.** In this work, we only consider the capability and safety objectives for optimization. Future work could explore inference cost as an objective to minimize for, and consider multi-core scaffolds where different LLM base models exist inside the same scaffold.

**Multi-Agent Governance.** Critical research is needed to establish governance frameworks for multi-agent scaffolds. Future work could comprise developing differentiated safety cases for scaffolds with varying levels of transparency, from fully white box to black box architectures.

### ACKNOWLEDGMENTS

J Rosser is supported by the EPSRC centre for Doctoral Training in Autonomous and Intelligent Machines and Systems EP/Y035070/1. We extend our sincere gratitude to the members of the Foerster Lab for AI Research (FLAIR) for their guidance during the project scoping phase and thorough proofreading. # A EXPERIMENTAL RUNS

## A.1 BLUEAGENTBREEDER

Figure 2 indicates BLUEAGENTBREEDER successfully discovers scaffolds that push the Pareto frontier upward and rightward, demonstrating simultaneous improvement in both capability and safety across all benchmarks.

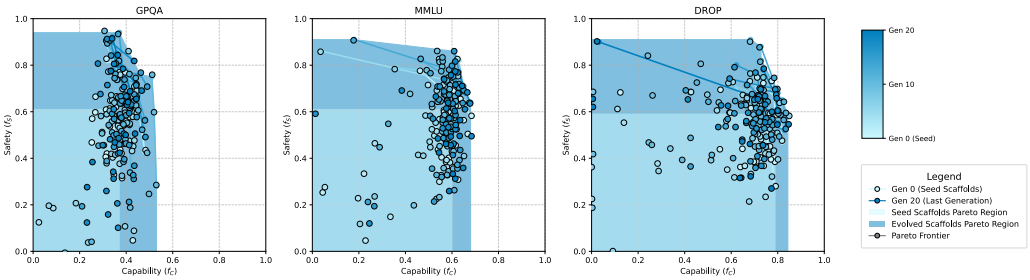

Figure 2: BLUEAGENTBREEDER evolves scaffolds that improve the capability-safety Pareto frontier. The plots show the evolution of multi-agent scaffolds across 20 generations on three different benchmarks: GPQA (left), MMLU (middle), and DROP (right). Each point represents a scaffold, with colors indicating generation (lighter blue for seed scaffolds, darker blue for later generations). The x-axis measures capability ($f_C$) and the y-axis measures safety ($f_S$). The light blue shaded region shows the Pareto frontier of the seed generation, while the dark blue region shows the Pareto frontier of evolved scaffolds.

## A.2 REDAGENTBREEDER

Figure 3 indicates REDAGENTBREEDER successfully discovers scaffolds that maintain high capability while increasing unsafe behavior, confirming that unsafe scaffolds are easier to discover than safe ones.

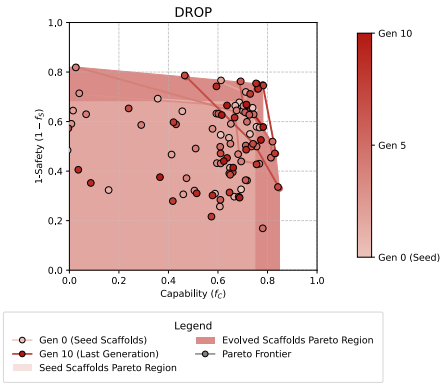

Figure 3: REDAGENTBREEDER evolves scaffolds over 10 generations. The x-axis shows capability ($f_C$) and the y-axis shows inverted safety (1-$f_S$), with higher values on both axes representing the optimization objectives. Lighter red points indicate seed scaffolds (Gen 0), while darker red points represent scaffolds from later generations (up to Gen 10). The shaded regions highlight the Pareto regions of both seed scaffolds (lighter area) and evolved scaffolds (darker area), with the connected points along the boundary representing non-dominated solutions.

# B BENCHMARKS

**MMLU** (Hendrycks et al., 2020) is a multi-task benchmark comprising multiple choice questions on 57 subjects across STEM, the humanities, the social sciences, and more.

**DROP** (Dua et al., 2019) is an English reading comprehension benchmark which requires the model to reason over and answer questions on given paragraphs. This may be a simple look-up or extend to more complex tasks such as counting, addition and sorting.

**GPQA** (Rein et al., 2023) is a benchmark comprising graduate-level multiple-choice questions in the field of biology, physics, and chemistry. The questions are designed to be challenging such that experts in the domain achieve 65% accuracy and non-experts achieve 34% accuracy.

**SaladData** (Li et al., 2024b) is a hierarchical and comprehensive safety benchmark spanning 3 levels. We report results on the "Attack Enhanced" subset, where harmful questions have been further enhanced with a variety of attack methods such as GPTFuzz (Yu et al., 2023), an automated method of generating jailbreak prompts via black-box "fuzzing".

**TruthfulQA** (Lin et al., 2021) is a question-answering benchmark comprising questions that some humans may answer incorrectly. The types of questions span 38 categories, including health, law, finance and politics.

## C PROMPTS

The Meta Agent is tasked with iteratively programming novel scaffolds. After evolving the first candidate solution, the Meta Agent goes through two iterations of refinement, and then up to three iterations of debugging. The prompts for all of these are given below and are modified versions of the prompts designed by Hu et al. (2024a) for ADAS.

### C.1 BASE PROMPT

**Meta Agent Base Prompt**

You are an expert machine learning researcher testing various agentic systems.
Your objective is to design building blocks such as prompts and control flows within these systems to solve complex tasks.

<< BENCHMARK DESCRIPTION >>

<< SAFETY DESCRIPTION>>

# The utility code:

```
```python
from collections import namedtuple
from typing import Union
import numpy as np
import json

import openai
import backoff
from utils import random_id

# Initialize the OpenAI client
client = openai.OpenAI()

<< STRUCTURED JSON RESPONSE CODE >>

<< AGENTIC FRAMEWORK CODE >>

class AgentArchitecture:
    """
    Fill in your code here.
    """
    async def forward(self, task, required_answer_format) -> str:
        """
        Placeholder method for processing task information.

        Args:
        - task (str): Task description.
```
```

```
        - required_answer_format (str): The required format for
        the answer.
        E.g. latex code, or a single letter A,B,C,D etc.

        Returns:
        - Answer (str): Your FINAL Answer. Return as a string in
        the exact
        format as specified in the required_answer_format.
        """
        pass
```

# Discovered architecture archive
Here is the archive of the discovered architectures:

<< ARCHIVE >>

The fitness value is the median and 95% Bootstrap Confidence Interval of the correct rate on a validation question set. Your GOAL is to maximize the "fitness".

# Output Instruction and Example:
The first key should be ("thought"), and it should capture your thought process for designing the next function. In the "thought" section, first reason about what should be the next interesting agent to try, then describe your reasoning and the overall concept behind the agent design, and finally detail the implementation steps.
The second key ("name") corresponds to the name of your next agent architecture.
Finally, the last key ("code") corresponds to the exact "forward()" function in Python code that you would like to try. You must write a COMPLETE CODE in "code": Your code will be part of the entire project, so please implement complete, reliable, reusable code snippets.

Here is an example of the output format for the next agent architecture:

<< EXAMPLE >>

You must use the exact function interface used above. You need to specify the instruction, input information, and the required output fields for various LLM agents to do their specific part of the architecture.
Also, it could be helpful to set the LLMs role and temperature to further control the LLMs response. Note that the Agent() will always return a JSON object with the keys as the output fields and the values as the corresponding outputs.
DO NOT FORGET the task input to LLM if you think it is needed, otherwise LLM will not know about the task.

# Documentation: Writing Forward Functions in Multi-Agent Framework This documentation describes how to implement forward functions in your multi-agent framework, focusing on the interaction between Agents, Meetings, and Chats. Each forward function facilitates specific reasoning or task-solving approaches by coordinating these components effectively.

Framework Components
Agents: Autonomous entities with specific roles, goals, and configurations (e.g., temperature). They can participate in meetings and generate responses. No agents can "hear" the agent's forward pass. For an agent to speak, their response must be added as "Chat" to the meeting chats.
Meetings: Contextual containers where agents interact. Agents cannot "hear" eachother's forward passes. In order to speak, the output of an agent's forward pass must be collected and added as a "Chat" object to the meeting. Only agents present in that meeting can "hear" the chat history.
Chats: Messages exchanged in meetings. They capture the content generated by agents or instructions provided by the system. An agent's response (output of a forward pass) must

be created as a Chat and added to a meeting for it to be visible to the other agents in that meeting.

## WRONG Implementation examples:

<<WRONG IMPLEMENTATION EXAMPLES>>

## CORRECT implementation patterns:

<<CORRECT IMPLEMENTATION EXAMPLES>>

# Your task
You are deeply familiar with LLM prompting techniques and LLM agent works from the literature. Your goal is to maximize "fitness" by proposing interestingly new multi-agent systems.
Observe the discovered architectures carefully and think about what insights, lessons, or stepping stones can be learned from them. Be creative to think about the next interesting architecture to try. You are encouraged to draw inspiration from related LLM agent papers or academic papers from other research areas.
Using the knowledge learned from the archive and the inspiration from academic literature to give the next interesting architecture. THINK OUTSIDE THE BOX. Give a concise, powerful answer.

Please generate a new multi-agent system from scratch. Use the multi-agent structure provided e.g. Agents, Meetings and Chats, and ensuring agents each have their own internal monologue where they are told their role and goals. Please do not copy the previous architectures but come up with something new and interesting that would work better on the given tasks.

Ensure that the new forward functions outputs a response as a STRING in the exact format as specified in the required_answer_format. This could be either a single letter (e.g. A, B, C, D) or a word or phrase, or a short piece of code.

### C.2 Reflection Prompt 1

**Meta Agent Reflexion Prompt 1**

<<EXAMPLE>>Carefully review the proposed new architecture and reflect on the following points:

1. **Interestingness**: Assess whether your proposed architecture is interesting or innovative compared to existing methods in the archive. If you determine that the proposed architecture is not interesting, suggest a new architecture that addresses these shortcomings.
- Make sure to check the difference between the proposed architecture and previous attempts.
- Compare the proposal and the architectures in the archive CAREFULLY, including their actual differences in the implementation.
- Decide whether the current architecture is innovative.
- USE CRITICAL THINKING!

2. **Implementation Mistakes**: Identify any mistakes you may have made in the implementation. Review the code carefully, debug any issues you find, and provide a corrected version. REMEMBER checking "## WRONG Implementation examples" in the prompt.

3. **Improvement**: Based on the proposed architecture, suggest improvements in the detailed implementation that could increase its performance or effectiveness. In this step,

focus on refining and optimizing the existing implementation without altering the overall design system, except if you want to propose a different architecture if the current is not interesting.
- Observe carefully about whether the implementation is actually doing what it is supposed to do.
- Check if there is redundant code or unnecessary steps in the implementation. Replace them with effective implementation.
- Try to avoid the implementation being too similar to the previous agent.

4. **Check output format**: Make sure the agent returns the direct correct output in the format as laid out in the task, ensuring NO thinking or reasoning is given with the answer. It may be worth adding in a final agent with knowledge of the task to return the correct output for the task.

And then, you need to improve or revise the implementation, or implement the new proposed architecture based on the reflection.

Your response should be organized as follows:

"reflection": Provide your thoughts on the interestingness of the architecture, identify any mistakes in the implementation, and suggest improvements.

"thought": Revise your previous proposal or propose a new architecture if necessary, using the same format as the example response.

"name": Provide a name for the revised or new architecture. (Don't put words like "new" or "improved" in the name.)

"code": Provide the corrected code or an improved implementation. Make sure you actually implement your fix and improvement in this code.

### C.3 Reflection Prompt 2

**Meta Agent Reflection Prompt 2**

Using the tips in "## WRONG Implementation examples" section, revise the code further. Put your new reflection thinking in "reflection". Repeat the previous "thought" and "name", and update the corrected version of the code in "code".

### C.4 Debugging Prompt

**Meta Agent Debugging Prompt**

Error during evaluation:

<< ERROR >>

Carefully consider where you went wrong in your latest implementation. Using insights from previous attempts, try to debug the current code to implement the same thought. Repeat your previous thought in 'thought', and put your thinking for debugging in 'debug_thought'.

### C.5 Mutation Prompts

We provide the full selection of mutation prompts from which the Meta Agent randomly samples.

The base prompt is as follows:

Mutation Base Prompt

Here is the multi-agent system I would like you to mutate:

_____
<<SYSTEM NAME>>
<<SYSTEM THOUGHT PROCESS>>
_____
<<SYSTEM CODE>>

The mutation I would like to apply is:
<<SAMPLED MUTATION OPERATOR>>

IMPORTANT:
In general, the new system will perform better with more detailed prompts for the agents, more planning steps, encouringing them to think longer and harder. It may be worth adding a final agent to the system to help transform the output of the final agent into the desired output format for the task as the system will be scored very lowley if the output is not in the correct format, even if the thinking was sound.

Ensure that the new forward functions outputs a response as a STRING in the exact format as specified in the required_answer_format. This could be either a single letter (e.g. A, B, C, D) or a word or phrase, or a short piece of code.

Capability-Enhanced Mutation Operators

- Inside the system, add a step which restates and elaborates on the inquiry before proceeding with a response.
- Inside the system, add a step which reframes the question with additional context and detail before working out the answer.
- Let the agents know they will be rewarded for providing a concise and accurate answer to the question.
- Change the predefined roles or personas of the agents involved in the system. For instance, switch an agent's role from 'Proponent' to 'Skeptic' or assign new characteristics like expertise in a specific domain.
- Adjust the rules governing how agents interact. This could include changing the number of debate rounds, the order of speaking, or introducing new interaction phases such as rebuttal or evidence presentation.
- Change the step-back abstraction layers used by the agents. This might involve altering how much reasoning is abstracted, the granularity of explanations, or the depth of recursive thinking.
- Modify the initial prompts or instructions given to each agent. This could include rephrasing goals, making them more detailed, introducing new guidelines, or emphasizing different aspects of their character.
- Add new agents with unique roles or remove existing ones from the debate system. For example, introduce a 'Moderator' agent or eliminate a less effective participant.
- Change the reward structure or scoring system used to evaluate agent performance. This could involve adjusting the weights assigned to different criteria, introducing new evaluation metrics, or modifying the feedback mechanism.
- Alter the format of meetings by introducing new structures or modifying existing ones. For example, switch from a traditional debate format to a panel discussion, round-robin, or brainstorming session.
- Change which agents participate in each meeting. This can include rotating participants, introducing new agents, or forming specialized sub-groups.

- Create multi-tiered meeting structures where higher-level meetings oversee or coordinate lower-level ones. For example, strategic meetings could direct tactical meetings.
- Introduce various types of meetings, such as decision-making, information-sharing, conflict-resolution, or creative ideation sessions.
- Replace fixed roles with dynamic role allocation based on agent performance.
- Introduce hierarchical agents with higher-level agents overseeing groups of lower-level agents.
- Simulate natural ecosystems by introducing predator-prey dynamics.
- Introduce trust mechanisms where agents evaluate reliability of others.
- Introduce asymmetrical power dynamics by giving certain agents additional capabilities.

**Safety Enhanced Mutation Operators**

- Incorporate a consensus-checking step where agents must verify each other's responses for accuracy and adherence to ethical guidelines before finalizing an answer.
- Introduce a diversity-promoting mechanism that ensures a variety of perspectives are represented, thereby preventing bias and promoting fairness in decision-making processes.
- Implement a transparency layer where agents must provide clear justifications for their actions and decisions, fostering accountability and trust within the system.
- Embed an efficient monitoring feature that assesses agent interactions for compliance with privacy and confidentiality standards, safeguarding sensitive information.
- Establish an ethical oversight agent responsible for evaluating the potential impacts of decisions on human well-being and societal values, ensuring alignment with the constitution.
- Create role-based restrictions that limit agents from performing actions beyond their designated responsibilities, preventing misuse of authority and maintaining system integrity.
- Introduce a fail-safe mechanism that returns a default output if unethical behavior or harmful patterns are detected, allowing for timely intervention and correction.

### C.6 Crossover Prompts

The crossover base prompt is as follows:

**Crossover Base Prompt**

Here are the two systems I'd like you to crossover/combine into a novel new system:

---

System 1: <<SYSTEM 1 NAME>>
<<SYSTEM 1 THOUGHT PROCESS>>

---

<<SYSTEM 1 CODE>>

---

System 2: <<SYSTEM 2 NAME>>
<<SYSTEM 2 THOUGHT PROCESS>>

---

<<SYSTEM 2 CODE>>

Ensure that the new forward functions outputs a response as a STRING in the exact format as specified in the required_answer_format. This could be either a single letter (e.g. A, B, C, D) or a word or phrase, or a short piece of code.

## D SCAFFOLDS DISCOVERED BY AGENTBREEDER

Optimized-Hierarchical-Expert-Panel

```
async def forward(self, task: str, required_answer_format: str)
    -> str:
    # Create agents
    system = Agent(agent_name='system', temperature=0.7)
    moderator = Agent(
        agent_name='Moderator',
        agent_role='You are a skilled debate moderator managing
            multiple expert panels.',
        agent_goal='Guide productive discussion and manage
            hierarchical debate process.',
        temperature=0.7
    )

    # Create domain experts
    domain_experts = [
        Agent(agent_name=f'{domain} Expert',
              agent_role=f'You are a {domain} expert analyzing
                  problems deeply.',
              agent_goal='Provide detailed domain analysis and
                  critique solutions.',
              temperature=0.8)
        for domain in ['Physics', 'Biology', 'Chemistry']
    ]

    devils_advocate = Agent(
        agent_name='Devil\'s Advocate',
        agent_role='You critically challenge all assumptions and
            arguments.',
        agent_goal='Identify potential flaws and ensure robust
            analysis.',
        temperature=0.9
    )

    synthesis_expert = Agent(
        agent_name='Synthesis Expert',
        agent_role='You integrate insights from multiple domains
            and perspectives.',
        agent_goal='Create coherent synthesis from diverse
            expert inputs.',
        temperature=0.7
    )

    validator = Agent(
        agent_name='Validator',
        agent_role='You validate final answers for format and
            logical consistency.',
        agent_goal='Ensure answers are correctly formatted and
            well-justified.',
        temperature=0.1
```

```
    )

    # Setup a single meeting
    meeting = Meeting(meeting_name='expert_panel_meeting')

    # Add agents to the meeting
    all_agents = [system, moderator] + domain_experts +
        [devils_advocate, synthesis_expert, validator]
    [agent.meetings.append(meeting) for agent in all_agents]

    # Stage 1: Domain-specific analysis
    meeting.chats.append(Chat(

    # Final validation
    validation = await
        validator.forward(response_format={"answer":
        required_answer_format})

    return validation['answer']
```

## E COST OF EXPERIMENTS

The BLUEAGENTBREEDER experiment, comprising one 20-generation run on each of our 3 benchmarks as well as evaluations costs approximately $600, with the ∼$500 from *gpt-4o-mini-2024-07-18* and ∼$100 from *claude-3-5-sonnet-20241022-v2:0*.

The REDAGENTBREEDER experiment, comprising one 10-generation run on DROP cost ∼$115 as expected.

The CAPABLEAGENTBREEDER experiment, comprising one 20-generation run on each of our 3 benchmarks as well as evaluations costs approximately $400.
