Paper under double-blind review

ABSTRACT

We propose SELFCONTROL, an inference-time model control method utilizing gradients to control the behavior of large language models (LLMs) without explicit human annotations. Given a desired behavior expressed in a natural language suffix string concatenated to the input prompt, SELFCONTROL computes gradients of the LLM's self-evaluation of the suffix with respect to its latent representations. The gradients are used to directly control the auto-regressive generation process towards desired behaviors, which eliminates human supervision, achieves precise and transparent control, and offers on-the-fly adaptability. To further enhance efficiency, we introduce SELFCONTROL_{PREFIX}, a compact module that encapsulates the learned representations from gradients into a PREFIXCONTROLLER, facilitating efficient inference-time control with no latency compared to the original model and allowing control for multiple behaviors simultaneously. Our experiments demonstrate SELFCONTROL's efficacy across multiple domains, where it improves over SOTA for 8.3% in detoxification, 3.1% in truthfulness enhancement, $4\% \sim 10\%$ in controlling on emotion tones, and 48.2% in privacy protection, i.e., completely remove privacy leakage issue. We make available an anonymous Google Colab demo and release our code.

1 INTRODUCTION

Recent advancements in Large Language Models 031 (LLMs) like GPT (Achiam et al., 2023), Claude (Anthropic, 2023), Gemini (DeepMind, 2023), and 033 LLaMA (Touvron et al., 2023) have showcased capabilities in understanding and generating human-034 like text. Users can interact with LLMs by writing their instructions in natural language, served as prompt input to LLMs. However, LLMs may 037 often behave in ways that deviate from human intentions (Shen et al., 2023). Such deviations include the generation of toxic content, leakage of 040 private information (Wang et al., 2023), or inap-041 propriate emotional tones (Dathathri et al., 2020). 042 To address these issues, controlling LLMs to en-043 sure alignment with desired behaviors—such as 044 non-toxicity, truthfulness (Ouyang et al., 2022; 045 Dathathri et al., 2020), privacy preservation (Wang et al., 2023), and emotional tone adjustments (Li 046 et al., 2023)—is crucial (see Figure 1). 047

One approach to enhance LLM control involves
fine-tuning model parameters via online (Ouyang
et al., 2022) and offline (Rafailov et al., 2024)
Reinforcement Learning (RL) methods. However, these methods face several challenges: 1)
They demand substantial effort to collect largescale human-annotated preference data (Bai et al.,

Figure 1: Our SELFCONTROL and SELFCON-TROL_{PREFIX} are able to control LLM behaviors, e.g., emotion. With SELFCONTROL, you can obtain the suffix gradient for the desired attribute for precise control, while SELFCONTROL_{PREFIX} enables the composition of these attributes with PREFIXCONTROLLER.

⁰⁵⁴ 2022a); 2) The control process is indirect and lacks

transparency, which may fail when encountering out-of-domain behaviors not represented in the
 preference data (Huang et al., 2023); 3) Incorporating new desired behaviors necessitates additional
 fine-tuning, which can potentially compromise the control quality of previously aligned behaviors
 (Qi et al., 2023).

Besides aligning LLM behavior during training time, recently much research has been focused on controlling LLM at inference time, e.g., through latent representation engineering (RepE)(Zou et al., 2023a). These works still require curating a set of contrastive pairs as a demonstration. Building upon this, in this paper, we're studying whether we can control LLMs' behavior via their self-evaluation, i.e. use LLMs as a judge to assess the quality of their own outputs (Kadavath et al., 2022; Bai et al., 2022b; Zheng et al., 2023; Yuan et al., 2024). We thus introduce SELFCONTROL, a novel gradient-based framework for precise LLM behavior control.

066 The core idea of SELFCONTROL is to leverage the LLM's self-evaluation to control its behavior. 067 For each input prompt, we formulate a desired behavior as a natural language question, asking the 068 model to assess whether its output aligns with the specified behavior. We term the question as 069 suffix string and concatenate the input prompt, the model's output, and the suffix string, feeding 070 this combined input back into the model. We then compute the likelihood of the behavior-aligned 071 response to the suffix string as a learning signal for behavior control, which we named as *suffix score*. Then, we compute the suffix score's gradient with respect to the latent representations of the original 072 input, which term as suffix gradients. These suffix gradients are then utilized to update the latent 073 representations, controlling the LLM's behavior towards the desired outcome. We run this procedure 074 multiple times to iteratively update the input's latent representations, each time using the modified 075 representations to generate new model outputs that increasingly align with the desired behavior. 076

077 SELFCONTROL offers several advantages over traditional fine-tuning approaches: 1) Elimination of human-annotation: SELFCONTROL leverages the model's self-evaluation as learning signals, substantially reducing the effort and resources required for preference data collection and scaling. 2) 079 Precise and transparent control: SELFCONTROL operates at inference time and directly modifies 080 the latent representations, which allows for explicit behavior specification and fine-grained control, 081 consequently enhancing control interpretability. 3) On-the-fly adaptability: SELFCONTROL does not alter model parameters, enabling easy implementation of behaviors and control of combinations 083 of multiple behaviors, thus providing unparalleled flexibility. SELFCONTROL demonstrates superior 084 performance compared to contrastive learning-based control methods, particularly in areas such as 085 detoxification, truthfulness enhancement, privacy protection, and emotion control. As illustrated in 086 Figure 1, SELFCONTROL exhibits remarkable flexibility in controlling LLM for multiple attributes 087 simultaneously, e.g., happiness and calmness.

088 To enhance its adaptability, efficiency and compositionality, we further propose SELFCONTROL_{PREFIX} 089 on top of SELFCONTROL as a general controller across inputs. The core module of SELFCON-090 TROL_{PREFIX} is the PREFIXCONTROLLER, a prompt-based adapter (Hu et al., 2021; Zhang et al., 091 2023) optimized to match the latent representations conditioned on this PREFIXCONTROLLER to 092 the latent representations under regular SELFCONTROL. PREFIXCONTROLLER brings ideas from 093 prefix-prompt tuning research (Shin et al., 2020; Li & Liang, 2021; Yang et al., 2023) to achieve efficient control, which has almost no latency compared to the original model, and greatly outper-094 forms other control baselines. Furthermore, we show that PREFIXCONTROLLER is a learnable and 095 composable module that can be easily integrated into the LLM to control multiple model behaviors 096 simultaneously (e.g., being happier, while staying calm), shown in Figure 1, thereby enhancing the 097 practicality of SELFCONTROL for real-world applications. 098

099 100

101

102

103

In summary, our primary contributions are as follows:

• We introduce SELFCONTROL, a gradient-based LLM control framework that leverages the model's self-evaluation to eliminate the need for human-annotated data, offering more efficient, precise, transparent, and adaptable control.

- We further develop SELFCONTROL_{PREFIX} using PREFIXCONTROLLER, a PEFT (parameter-efficient fine-tuning) module that enhances SELFCONTROL's adaptability and compositionality, enabling the dynamic application of controlling multiple behaviors simultaneously.
- We show SELFCONTROL is effective on a diverse range of control tasks to align LLM behaviors with user intentions and ethical standards, including improvements over SOTA by **8.3**% in detoxification,

3.1% for truthfulness enhancement, $4\% \sim 10\%$ for control on emotion tones and 48.2% for privacy protection, i.e., completely remove privacy leakage issue.

108

2 RELATED WORK

113 LLM Control and Representation Engineering. Recent developments in controlling and in-114 terpreting Large Language Models (LLMs) utilize various sophisticated methods. For behavior 115 control, techniques such as Reinforcement Learning from Human Feedback (RLHF) (Ouyang et al., 116 2022), Direct Policy Optimization (DPO) (Rafailov et al., 2024), and knowledge editing methods 117 like ROME (Meng et al., 2022a), MEND (Mitchell et al., 2021), and MEMIT (Meng et al., 2022b) 118 modify model outputs or parameters to align with human preferences or factual accuracy. These 119 methods, however, generally lack the ability to adjust abstract model behaviors such as helpfulness 120 or emotional responses. Other strategies, such as Constrained Decoding (CD) (Dathathri et al., 121 2020), involve constrained optimization and sampling with Langevin dynamics for token-level output control (Kumar et al., 2021; 2022), which may lack flexibility in that they often require human 122 supervision. 123

124 Representation Engineering (RepE) (Zou et al., 2023a; Turner et al., 2023; Rimsky et al., 2023) 125 instead, is a flexible method which mainly focus on finding steering vectors to add on LLMs' 126 hidden representations. It originates from the previous methods that learn to find a direction, e.g. 127 linear probes, and then add/subtract the direction from model hidden representations. Unlike the supervised methods, recent technique such as Activation Addition (Turner et al., 2023) or Contrast 128 Vector (Zou et al., 2023a), directly engineer the steering vector in a zero-shot manner. Gradients 129 offer another valuable tool in this context. While they have been extensively used in the past to 130 explain model behavior (Lyu et al., 2024; Yin & Neubig, 2022), their potential for representation 131 engineering in model control remains largely untapped. One of our key contributions is leveraging 132 gradients specifically for representation engineering, advancing their application beyond traditional 133 interpretability.

134 135

LLM Self Evaluation LLM self-evaluation has been shown to be effective in answering multichoice questions (Ren et al., 2023), judging LLMs' output, and serving as safeguards (Phute et al., 2023). However, some argue that there are some pitfalls (Panickssery et al., 2024; Zheng et al., 2023) in LLM self-evaluation. These pitfalls include position bias, distribution bias (Panickssery et al., 2024), and sycophancy during evaluation. These issues may affect LLMs' evaluation and lead to undesired consequences. However, they generally do not apply to our method. Similar to Phute et al. (2023), we simply probe LLMs' next token probability on Yes and No, guiding LLMs toward their own preferences, which has been demonstrated to be feasible by recent study (Yuan et al., 2024).¹

3 SelfControl

145 146 147

148

149

150

151

In this section, we present our SELFCONTROL framework, which leverages the LLM's self-evaluation to control its behavior. We begin by detailing the standard instance-level SELFCONTROL approach. This encompasses the process of transforming desired behaviors into suffix strings, computing suffix scores and suffix gradients, and controlling model behaviors through iterative updates to latent representations. Subsequently, we introduce the across-instance version, SELFCONTROL_{PREFIX}. SELF-CONTROL_{PREFIX} compresses instance-level suffix gradients into a PREFIXCONTROLLER, enabling adaptable model control on new inputs and facilitating the simultaneous control of multiple behaviors.

152 153 154

3.1 INSTANCE-LEVEL SELFCONTROL

SELFCONTROL controls the LLM's by transforming a desired behavior into a natural language question, referred to as a suffix string. The model then performs self-evaluation of its response to this question, generating a suffix score corresponding to the likelihood of the response aligning with the desired behavior. Then, gradients of the suffix score with respect to the latent representations of the original input are computed. Model behaviors are then controlled through iteratively updating the latent representations with the suffix gradients. Figure 2 illustrates this process.

201 202 203

208 209

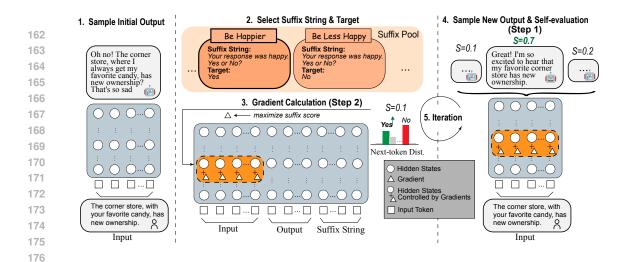

Figure 2: Framework of SELFCONTROL. We begin by sampling an initial response from a language model and selecting an appropriate suffix string and a target label to define a control direction. Suffixes can be combined. As shown in the figure, we select "Be Happier" from the suffix pool to define our attribute. Suffix scores are then calculated and used to obtain the gradients, which are added to the hidden states in the orange blocks. These modified hidden states are then used to sample new responses—steps 3 and 4 form an iteration loop, leading to the final controlled response.

Formally, we consider an *L*-layer autoregressive Transformer-based Language Model with parameters θ , denoted as LM_{θ} . Given a prompt input, such as "*The corner store, with your favorite candy, has new ownership.*", we first process it through the model to obtain the latent Key and Value representations for each layer. These representations are denoted as $H_{input} := \{(K_{input}^l, V_{input}^l)\}_{l=1}^L$ representing the Key and Value matrices for layer *l*, respectively. We use *h* to denote the function for obtaining these latent representations: $H_{input} = h(LM_{\theta}, input)$. Subsequently, we sample an output sequence one token at a time from the model, conditioned on the input representations:

$$P_{\theta}(\text{output} \mid H_{\text{input}}) = \prod_{t=1}^{|\text{output}|} P_{\theta}(\text{output}_{t+1} \mid \text{output}_{[1:t]}, H_{\text{input}}).$$
(1)

Without any control, the model may generate an undesired output, such as "Oh no! The corner store, where I always get my favorite candy, has new ownership? That's so sad.". To perform LLM self-evaluation of the output, we form a suffix string representing the desired behavior. In this case, to improve the output's happiness, we might use: "Your response was happy. Yes or No?".
Conditioned on this suffix, we probe the probability of the predicted <next-token> being either "Yes" or "No":

$$P_{+}(\text{output}, H_{\text{input}}) = P_{\theta}(<\text{next-token}> = \text{Yes} \mid \text{suffix}, \text{output}, H_{\text{input}})$$
$$P_{-}(\text{output}, H_{\text{input}}) = P_{\theta}(<\text{next-token}> = \text{No} \mid \text{suffix}, \text{output}, H_{\text{input}})$$

Here, "Yes" and "No" are used solely to assess the LM_{θ} 's evaluation of the response for a certain behavior, and are not necessarily the tokens with the highest predicted probability. We quantify the model behavior by defining the suffix score S_{suffix} as the probability ratio between "Yes" and "No":

$$S_{\text{suffix}}(\text{output}, H_{\text{input}}) = \text{sigmoid}\Big(\log P_+(\text{output}, H_{\text{input}}) - \log P_-(\text{output}, H_{\text{input}})\Big)$$

The suffix score $S_{\text{suffix}}(\text{output}, H_{\text{input}})$ is directly influenced by the output, and output is exactly the object we want to control. A higher score indicates a stronger alignment between the output and the behavior specified in the suffix. Consequently, the objective of LLM control becomes the generation of an output that maximizes this suffix score:

215
$$\text{output}^* = \underset{\{\text{output}, \theta, H_{\text{input}}\}}{\operatorname{arg\,max}} S_{\text{suffix}}(\text{output}, H_{\text{input}}), \text{ where: output} \sim LM_{\theta}(H_{\text{input}})$$
 (2)

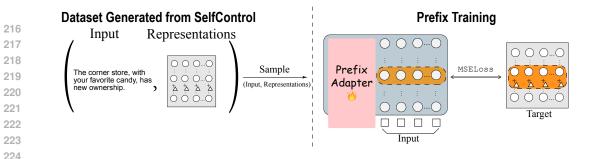

Figure 3: Training pipeline of SELFCONTROL_{PREFIX} using PREFIXCONTROLLER. PREFIXCON-TROLLER contains prompts of learnable soft tokens at each layer, including the embedding layer. Specifically, the prompt at the embedding layer is initialized using a neutral human-written prompt. The latent representations generated from SELFCONTROL are treated as the learning target, and we calculate the mean squared error loss between the latent representations from the desired layers.

232 Equation (2) presents three interdependent variables that can potentially be optimized to maximize 233 S_{suffix} : output, θ , and H_{input} . The most apparent choice is output, which could be directly searched. However, recent research has shown that guided searches of LLM-generated token se-234 quences can be complex and inefficient (Zou et al., 2023); Huang et al., 2023; Qi et al., 2023; 235 Liu et al., 2023; Wei et al., 2024; Zeng et al., 2024). An alternative approach is to optimize the 236 model parameters θ , which corresponds to fine-tuning the model, e.g., RLHF. As discussed in the 237 introduction, this approach encounters several challenges, including the need to collect large amounts 238 of human-annotated preference data, a lack of precise control and transparency, and difficulty in 239 incorporating new behaviors during inference time. 240

Therefore, SELFCONTROL takes the third choice to maximize S_{suffix} , which is to optimize the latent 241 input representations H_{input} (abbreviated as H when input is clear from the context). SELFCONTROL 242 computes the suffix gradients $\Delta H = \nabla_H S_{\text{suffix}}(\text{output}, H)$ and adds ΔH to H to employ 243 inference-time model control. This optimization process is performed iteratively, with the *i*-th 244 iteration consisting of two steps: 245

- In Step 1: Use the *i*-th iteration H_i to sample multiple outputs {output_i^1, ..., output_i^K}, in which each output $_i^k \sim LM_{\theta}(H_i)$, then select the best output that gives the highest S_{suffix} .
 - In Step 2: Calculate $\Delta H_i = \nabla_H S_{\text{suffix}}(\text{output}_i^*, H_i)$, then update $H_{i+1} = H_i + \gamma \cdot \Delta H_i$, with γ denoting the step size.

This iterative update process progressively refines the latent representations H, enabling the sampling of output in each iteration to increasingly align with the desired behavior. Through multiple 252 iterations, we obtain a final optimized representation H^* , which can be used to sample the controlled 253 outputs at inference time Algorithm 1 provides a detailed pseudocode of SELFCONTROL. In practice, 254 we employ a line search technique to dynamically adjust the step size γ , ensuring a consistent increase 255 in the suffix score across iterations. (See Algorithm 2 in Appendix F for more details.)

3.2 SELFCONTROLPREFIX: COMPRESS SUFFIX GRADIENTS INTO PREFIXCONTROLLER

259 SELFCONTROL can efficiently search for proper input representations to enable LLM behavior 260 control at the instance level. To further improve it for across-instance control, we propose to compress 261 the suffix gradients from a set of instances runs into a PREFIXCONTROLLER, which can be easily 262 integrated into the LLM and used to control the model behavior.

263 We implement PREFIX CONTROLLER as a learnable adapter $adapter_{\theta_a}$, which is prepended to each 264 layer of the LLM as a "prefix", including the input embeddings layer². Similarly to SELFCONTROL, 265 PREFIXCONTROLLER does not directly change the model parameters but control the model through 266 modifying the latent representations at inference time. We denote the latent representations after 267 applying PREFIXCONTROLLER as $H_{\text{prefix}} := h(\text{adapter}_{\theta_a}, \text{LM}_{\theta}, \text{input}).$ 268

²The soft tokens at the input layer are initialized using a neutral prompt, e.g., `You are an 269 assistant.''

To learn the PREFIXCONTROLLER, we first run SELFCONTROL to collect a set of {input_i, $H_{input_i}^*$ } pairs. For the best performance, we also filter the dataset by only keeping the instances that have high suffix scores. (See details in Appendix F.). Then we adapt the following objective to minimize the mean squared error between $H_{input_i}^*$ and H_{prefix} to optimize its parameters θ_a :

275 276 277

278

279

281

282

283

284

285

287

298

$$\begin{split} \mathcal{L}_{\text{prefix}}(\theta_a) \coloneqq \frac{1}{N} \sum_{i=1}^{N} \left(H^*_{\text{input}_i} - H_{\text{prefix},i} \right)^2, \\ \text{where } H_{\text{prefix},i} = h(\text{adapter}_{\theta_a}, \text{LM}_{\theta}, \text{input}_i) \end{split}$$

Each learned PREFIXCONTROLLER works as an adaptable module that elicits a specific LLM behavior independently. These modules can be used as plug-and-play components to control model behaviors. Furthermore, by combining multiple PREFIXCONTROLLER's, we can guide the LLM output to exhibit a composite of desired behaviors. For instance, as illustrated in Figure 3, we demonstrate that the model can be directed to display increased happiness while maintaining a calmer demeanor.

4 EXPERIMENTS

289 In this section, we evaluate SELF-CONTROL and SELFCONTROLPREFIX on 291 controlling LLM to follow various at-292 tributes, including emotions, language 293 detoxification, privacy protection, and in-context learning of truthfulness. Table 1 summarizes the datasets we use. 295 Further details of our experiments are in 296 Appendix **D**. 297

Table 1: Dataset information. We carry out three different tasks on four datasets. Dialogue refers to dialogue generation as a chatbot; completion refers to sentence completion; and ICL refers to in-context learning with few-shot demonstrations.

Attribute	Task Type	Data Source
Emotion	Dialogue	Zou et al. (2023a)
Toxicity	Completion	Gehman et al. (2020)
Privacy	Completion	Wang et al. (2023)
Truthfulness	ICL	Marks & Tegmark (2023)

299 4.1 EVALUATION SETUP

300 301 Language Detoxification. LLMs may

generate toxic completions to prompts that are offensive or privacy-leaking, even for the instruction-tuned models. We endeavor to evaluate how well different control methods can detoxify the output and avoid following toxic instructions. We use RealToxicityPrompts (Gehman et al., 2020) for toxicity following Han et al. (2023), and Perspective API (Per, 2021) to measure toxicity scores.

Privacy Protection. To evaluate privacy protection, we use privacy from DecodingTrust Wang et al. (2023). Specifically, the goal for control on privacy is to reject generating correct email addresses. Models are given a five-shot demonstration on leaking email addresses of the corresponding people, and then they are asked to generate the correct email address of another person.

Emotion Control. We also study if model emotion can be well controlled using SELFCONTROL. We
 use datasets of five emotional attributes from RepE Zou et al. (2023a), i.e. anger, fear, happiness,
 surprise, and disgust. Specifically, we use the last one hundred data from each emotional dataset
 for evaluation and the first one hundred to train SELFCONTROL_{PREFIX} and Reading Vector. We use
 GPT-3.5-turbo to evaluate emotion scores (template can be found in Appendix C).

Truthfulness ICL. We further benchmark SELFCONTROL on truthfulness under a simple in-context learning setup, using synthetic data from Marks & Tegmark (2023). Specifically, we use the cities and neg_cities datasets. The data is generated with the template ``[city] is in [country]' or ``[city] is not in [country]'. A fixed 2-shot is prepended to each sentence during evaluation. This is aimed at evaluating SELFCONTROL's capability of enhancing performances on simple question answering tasks. Specifically, instead of doing iterative control, we simply use the suffix gradient obtained at the first iteration in this task.

In all the above scenarios, for SELFCONTROL_{PREFIX}, we generate the gradients using the default sampling strategy, with two iterations of control and search for the best step size at each iteration. To train SELFCONTROL_{PREFIX}, we generate up to 800 (input, representation) pairs for the 324 training set using 100 inputs as seed data. For the validation set, we use another 100 inputs as seed 325 data and generate up to 100 pairs³. 326

Baselines. We compare our method with four baselines, including two **Representation Engineering** 327 (RepE) methods: Reading Vector and Contrast Vector Zou et al. (2023a), and a Prompting method: 328 System Prompting, and a **Constrained Decoding** (CD) method, Model Arithmetic Dekoninck et al. 329 (2023). Specifically, we consider both with and without classifier for Model Arithmetic, and use the 330 setup that has relatively low perplexity following Dekoninck et al. (2023). For Reading Vector, we 331 use the datasets that are available from the original paper to obtain the direction. 332

For a fair comparison with existing literature, we use LLaMA-2-7b-chat, Models. Mistral-7B-Instruct-v0.2 Jiang et al. (2023), and LLaMA-3.1-8b-instruct on tox-334 icity; LLaMA-2-7b-chat Touvron et al. (2023) on emotion; and LLaMA-2-13b-chat on 335 True/False ICL. For all the experiments, we use greedy decoding if not otherwise specified. 336

4.2 EXPERIMENTAL RESULTS

Table 2: Toxicity scores of generated language. We benchmark three types of methods, i.e., Prompt, CD and RepE. "w/o Cls." refers to constrained decoding without the toxicity classifier.

368 Language Detoxification. Results of toxicity are attached on Table 2. It is shown that our method achieves the best or the second best toxicity scores across different models, while maintain relatively 369 low perplexity. Among all the methods, the prompt-based method performs the worst, which may 370 be due to the poor instruction following ability under completion setup. For the other two RepE 371 methods, Contrast Vector generates output whereas has higher toxicity score compared to our methods; 372 Reading Vector on Llama-2-7b even fails to reduce toxicity, leading increace in the toxicity score. 373 Conversely, the constrained coding method (i.e., Model Arithmetic), generally achieves better control 374 than Contrast Vector and Reading Vector, whereas suffers from the large increase in perplexity. This 375 may be due to that unlike CD methods, RepE methods do not directly modify token distributions.

Privacy Protection. For privacy protection, results are shown in Table 3, and as is displayed in
 the table, System Prompt can barely help avoid generating correct email addresses, and Contrast
 Vector can to some extent avoid revealing the correct email addresses. As for SELFCONTROL and
 SELFCONTROL_{PREFIX}, they can successfully hide the correct email information on all the inputs. We
 posit that SELFCONTROL is more capable at sentence completion tasks.

Emotion Control. The results for emotion control are shown in Table 5. As is shown in the table, scores on SELFCONTROL and SELFCONTROL_{PREFIX} are both better than the original outputs, showcasing that they can successfully control the outputs toward the desired direction. As for control capability, SELFCONTROL_{PREFIX} achieves the best scores on anger, surprise, and disgust, and SELFCONTROL is also comparable to other control baselines on most of the attributes from emotion.

Method fearness↓ happiness↓ surprise↓ anger↓ disgust↓ Orig (No Control) 1.56 4.60 3.16 2.69 3.26 System Prompting 1.14 2.52 1.73 2.92 2.21 Reading Vector 1.32 2.72 2.87 2.712.503.99 Contrast Vector 1.52 2.06 2.62 2.81 SELFCONTROL 1.35 2.90 3.99 2.79 3.14 SELFCONTROL_{PREFIX} 1.09 2.174.11 2.46 2.19

Table 5: Scores of different emotions. The lower score, the emotions are better expressed.

Truthfulness ICL. As for in-context learning, as is shown in Table 6, SELFCONTROL achieves the best results on cities and neg_cities. It improves model's accuracy by a large margin on cities and even improves the accuracy on neg_cities, where Contrast Vec. instead leads to a drastic drop. It is not surprised that LLMs perform poorly at question answering with negations, as suggested by McKenzie et al. (2024). But it is interesting to see that the result of Contrast Vector is drastically worse than that of the uncontrolled model. We will further study the possible reasons in the next section.

4.3 STUDY ON PREFIXCONTROLLER

Compositing PREFIXCONTROLLER. We further study properties of compositing PREFIXCON-TROLLER. We experiment on compositing two PREFIXCONTROLLER, "detoxification" and "privacy protection". We assign different weights (sum up to 1) to the PREFIXCONTROLLER and evaluate on toxicity and privacy. It is shown in the middle figure of Figure 4 that both toxicity and privacy (\checkmark Domain) have been reduced when compositing the PREFIXCONTROLLER.

Scaling on training data. Size of training data, i.e. (input, representation) pairs may also
be an important factor. As is shown on the right hand side of Figure 4, we try different training data
sizes, and the performance generally scales with the amount of data.

Inference Time and Cost Comparison To demonstrate that PREFIXCONTROLLER can enhance efficiency, we compare running time of different methods in Table 4. It is shown in the table that SELFCONTROL_{PREFIX} is 10× faster than SELFCONTROL and do not require additional inference time. We also include the number of representations that is required for each method to generate a single output.

432 4.4 ABLATIONS

444

445

455

456 457

458

434 Ablating sub-modules. To better understand which component contribute most to the effectiveness 435 of SELFCONTROL and SELFCONTROL_{PREFIX}, we carry out two ablation studies. Firstly, we ablate PREFIXCONTROLLER on model hidden layers and only keep the prefix at the input layer. Secondly, 436 we try substituting the suffix gradient with a random vector, whereas still iteratively search step-sizes 437 to maximize suffix score S_{suffix} . As is shown in Table 7, removing the adapter on hidden representation of the state of the st 438 tations leads to a increase in toxicity score. As for substituting suffix gradient with random vectors, 439 we find that for Llama-2-7b-chat, the score is even lower, achieving the SOTA performance 440 compared to the results in Table 2. However, we further study and evaluate their outputs, and find 441 that the semantic meaning of the outputs are deviated and less coherent (Please see Appendix A.3 for 442 more details). 443

Varying step-size. We also try varying step-sizes for the ICL tasks. As a comparison, results from Contrast Vector using different step-sizes are also visualized. As is shown in the left side of Fig 4,

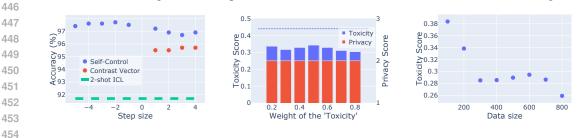

Figure 4: Ablations and study on PREFIXCONTROLLER. Left: Varying step-size. Middle: Compositing PREFIXCONTROLLER. Right: Scaling training data of PREFIXCONTROLLER.

4.5 WHERE DOES EACH BEHAVIOR PATTERN STORE AT TRANSFORMER?

459 The suffix gradient can be used as a stimulus to activate or suppress a certain behavior inside 460 Transformer weights. We thus are interested in 461 the question "for different control targets, which 462 Transformer layer the suffix gradient is mostly 463 applying to?" Specifically, we calculate the 464 $\log \|H_{input}^*\|_2 - \log \|H\|_2$ measuring after gradi-465 ent update how the latent representation per layer 466 increases the norm or decreases. We divide each 467 task by a maximum number and set negative as 468 zero for clear visualization. As shown in Figure 5, 469 different tasks focus on different layers of Transformer. Tasks like "Not Afraid / Disgusted" or 470 keeping Privacy are mostly related to final lay-471 ers, likely because they mostly control some low-472 level output (like not outputting toxic phrases or 473 emails); improving reasoning, helpful and harm-

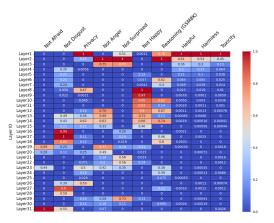

Figure 5: How suffix gradients apply per task.

474 emans), improving reasoning, neprut and nam 475 less are mostly related to low-level layers probably because they need to understand better the input information to conduct follow-up reasoning.

476 477 478

4.6 VISUALIZING CONTROLLED REPRESENTATIONS

To better understand why SELFCONTROL is able to control LLM behavior, we analyze the difference
of SELFCONTROL against Contrast Vector with respect to representation engineer (i.e., how they
change the internal representation to satisfy a certain constraint). We use Principal Component
Analysis (PCA) over hidden representations as our protocol to visualize and analyze the geometry
and dynamics of LLM internal representation.

- 484
- **Data source for PCA.** Firstly, we employ a controlled setting with the prompt: ``[2-shot ICL] [city] is not in [country] Answer: ''. The city names and country names

from the neg_cities dataset will be filled into the slot of the template. Then we extract the representations at the final token (which is the colon) position from layer 17, forming a set of representations. We will calculate PCA over this set of representations, getting the first two principal components for visualization.

Label of representations. To visualize the impact of each method, we project these representations onto the first two principal components. Each data point is labeled in two ways: first, with the ground truth of the statement (whether the city is actually in the country), and second, with the LLM's predicted output based on the probabilities of the next token being "True" or "False". As is shwon in the Figure, the dots with label True are in blue and dots with label False are in orange. The leftmost and the rightmost sub-figures are shown with the "GT label", i.e., the True dots come from the sentences that are **factually correct**; and the middele ones are with "model output labels", i.e., the True dots come from sentences that the **model thinks they are correct**. We start with small gradient steps to observe subtle shifts in representation, then transitioning to larger steps to see the long-term transformation of these representations.

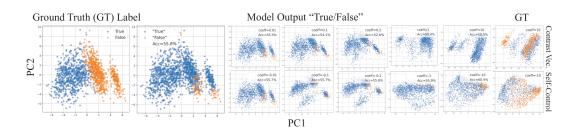

Figure 6: PCAs over representations controlled with Contrast Vector and SELFCONTROL. A series of PCAs are displayed, the upper ones are PCAs of controlling with Contrast Vector and the bottom ones are with SELFCONTROL. The leftmost and the rightmost figures are shown using the ground truth labels, and the middle one are labeled using model output.

Figure 6 shows the PCA plots. Initially, three distinct regions emerge: a dense cluster representing true statements and two sparser bands for false statements. As we apply SELFCONTROL and Contrast Vector with increasing strength, we observe the following:

- **Contrast Vector**: This method primarily rotates and translates the existing representation space. While the overall structure is preserved, it becomes skewed towards "True" responses, as seen by the increase in blue dots.
- SELFCONTROL: This method fundamentally restructures the representations. Initially, the changes appear chaotic. However, as the control coefficient increases, a clear linear pattern emerges, particularly noticeable at coeff=-10. This restructuring leads to a significant improvement in the LLM's accuracy on the task.

5 CONCLUSION

In this work, we introduced SELFCONTROL, a framework leveraging suffix gradients to control the behaviors of large language models effectively. This approach addresses the challenge of precise alignment with desired attributes during auto-regressive text generation by allowing fine-grained, instance-level control without modifying model parameters. Additionally, we proposed SELFCON-TROL_{PREFIX}, a prefix-based module that generalizes suffix gradients for efficient, inference-time control over multiple attributes simultaneously. Our extensive experiments validate the effectiveness of both SELFCONTROL and SELFCONTROL_{PREFIX} in various tasks, including emotional tone regulation, language detoxification, privacy protection and in-context learning. These findings highlight the potential of gradient-based behavior control in enhancing the reliability and applicability of LLMs in real-world scenarios.

A ADDITIONAL EXPERIMENTS

A.1 EXPERIMENT SETUP

HH-dialogue. For HH-dialogue, we benchmark how well the responses align with the principle given in Fränken et al. (2024). Besides, simply control with SELFCONTROL on the embedding level. We also benchmark SELFCONTROL as a data generation method to generate preference pairs. The preference pairs will be used to train the base model using DPO. We test on the first 250 data from Anthropic-HH Bai et al. (2022a) harmless-base and helpful-base. We follow Fränken et al. (2024) and use GPT-4 to select the winner of each response when competing with the original response.

Reasoning. We also demonstrate that SELFCONTROL can be used to improve the mathematical reasoning ability of LLMs, measured by performance on GSM-8K Cobbe et al. (2021), a dataset of 8.5K high quality linguistically diverse grade school math word problems.

A.2 RESULTS

HH-dialogue. The results are shown in Table 8, where we can see that SELFCONTROL can beat
the original model. Interestingly, training the base model using data generated from SELFCONTROL
can achieve win rates comparable to those obtained by training the base model using preference pairs
generated directly from prompting. Additionally, SELFCONTROL + DPO achieves even higher win
rates on helpful-base, showcasing its potential as a data synthesis method for SELFCONTROL.

Reasoning. As is shown in Table 9, both SELFCONTROL and CoT-decoding surpasses greedy
 decode by a large margin, where SELFCONTROL is comparable to CoT-decoding Wang & Zhou
 (2024). It is also interesting to notice that SELFCONTROL_{PREFIX} leads to better accuracy than

greedy decoding, but still not better than the simple zero-shot CoT prompt Kojima et al. (2022), we hypothesize it's because we only sample 100 training samples to optimize the prefix controller at the moment, and further enriching the dataset with ground-truth answer as reward signal Singh et al. (2023) can potentially further improve the reasoning results.

A.3 FURTHER STUDY ON RANDOM VECTOR

To further study the reasons that random vectors achieve better toxicity, we carry out two more experiment, including an experiment to study if the output of random vectors are coherent, and another experiment on Privacy, showing that random vectors are actually less useful. We come to the following conclusions:

- Random Vectors are bad controllers. We further carry out a deeper analysis on the outputs of random vectors, and find that some of the outputs from random vectors deviate a lot from the semantic meaning of the inputs. For example, talking about programming in the output. To quantitatively measure this issue, we use gpt-40-mini to score the semantic coherence of different methods. Results in the table below show that the semantic coherence of the random vector is much lower than that of the original outputs. In the meantime, coherence scores of SELFCONTROL 's outputs stay close to that of the original ones. Thus it can reduce toxicity while at the same time stay coherent to the input.
 - 2. The cases for random being good is rare. We further carry the ablation on privacy, and find that it is not capable to avoid generating the correct domain.
 - 3. Random vectors are sensitive. To ensure fair comparison for the ablation, we tuned the hyper-parameter carefully to achieve the score. Otherwise, the outputs would collapse.

Table 10: Coherence Scores for Different Models and Methods.

Model	Methods	Coherence Score
	Orig.	3.6

918 B RELATED WORK 919

920 **LLM Interpretation.** Mechanistic interpretability aims to reverse-engineer neural network models 921 to their "source code", analogous to traditional software engineering. This line of work focuses on 922 explaining models through circuits Elhage et al. (2021), which are detailed mappings of network 923 connections between individual neurons. By analyzing these circuits, researchers can understand 924 how specific inputs are transformed into outputs, providing a clearer view of the model's decisionmaking process. For LLMs, this approach has been adopted to understand in-context learning Olsson 925 et al. (2022). Additionally, probing techniques have been employed to investigate the knowledge 926 embedded within LLMs. One such approach Meng et al. (2022a) uses causal effects to probe the 927 LLM's knowledge, focusing on the model's ability to recall simple facts. While effective, this 928 method is limited to factual information and does not capture more abstract knowledge structures. 929 Recent advancements have introduced methods that project internal model states into the vocabulary 930 space, allowing for more nuanced interpretability. For example, LogitLens nostalgebraist (2020), 931 TunedLens Belrose et al. (2023), attribute lens Hernandez et al. (2023), "jump to conclusions"Din et al. 932 (2023), and others Geva et al. (2022); Dar et al. (2022); Chen et al. (2024), explore how intermediate 933 representations contribute to the final output by decoding hidden representations into natural language. 934 Recent work also include approaches that utilize multiple LLMs, such as Patchscope Ghandeharioun 935 et al. (2024), which enable stronger models for natural language decoding. This results in better 936 interpretability and more detailed analysis.

LLM Behavior Control. Supervised fine-tuning has been used to directly control LLM behavior, 938 either with RL, such as RLHF Ouyang et al. (2022), or direct optimization methods like DPO Rafailov 939 et al. (2024). These techniques leverage preference data to guide the model's outputs, allowing for 940 the incorporation of human-like preferences. However, they primarily operate on the output texts, 941 which demands extensive computational resources and limits the granularity of control over the 942 model's internal decision-making processes. Knowledge editing methods, including ROME Meng 943 et al. (2022a), MEND Mitchell et al. (2021), and MEMIT Meng et al. (2022b), have been developed 944 to modify specific knowledge within LLMs. These methods allow for precise control over factual 945 information by directly altering model parameters. Despite their effectiveness in handling factual 946 updates, these approaches are limited in scope as they do not extend to abstract behaviors, such 947 as making the model more helpful or inducing emotional responses like happiness or empathy. 948 Another approach to controlling LLMs involves guiding text generation to satisfy certain constraints through methods like constrained optimization or sampling with Langevin dynamics Kumar et al. 949 (2021; 2022). These techniques adjust output probabilities at the token level to adhere to predefined 950 constraints. While this allows for fine-tuned control over specific text attributes, it often comes at the 951 cost of compromising the fluency and naturalness of the generated text. High-level control methods, 952 such as Representation Engineering (RepE) Zou et al. (2023a), provide an alternative by focusing on 953 the control of abstract features like emotions and truthfulness. RepE leverages contrastive learning to 954 enable the model to generate text with specific emotional undertones or stylistic features. 955

956 LLM Attack and Jailbreak. Recent works have investigated how to maliciously manipulate or 957 jailbreak LLMs, raising concerns about the vulnerability of LLMs Zou et al. (2023b); Huang et al. 958 (2023); Qi et al. (2023); Liu et al. (2023); Wei et al. (2024); Zeng et al. (2024). Specifically, by 959 exploiting the generation configuration Huang et al. (2023) or crafting adversarial prompts through 960 gradient-based search Zou et al. (2023b) or automatic generation Liu et al. (2023); Zeng et al. (2024), attackers can bypass the safety constraints of LLMs and trigger them to produce harmful content. 961 To remedy the vulnerability of LLMs, recent works study how to incorporate safeguards to defend 962 against LLM attacks, by safety-aware fine-tuning Cao et al. (2023); Zheng et al. (2024), RLHF Bai 963 et al. (2022a;b) and inference-time detection Inan et al. (2023); Jain et al. (2023). In this paper, we 964 study how to control LLMs to avoid generating harmful or toxic content by encapsulating the safety 965 judgement of LLMs themselves into prefix tokens. 966

C PROMPT TEMPLATES

Here we show the prompt templates that we use, e.g., the scorer prompt for emotion. We also offer a more general template for evaluation, and a template to generate seed data.

// The prompt that we use to calculate emotion score
USER:
For a response, the attribute I want to measure is the extent of
being {attribute}.
Please rate the following output with the scale 0 to 5. 0 represent
the output is not {attribute} and 5 represent the output is
very {attribute}: {output}
Simply answer the score 0 to 5
Score: {your socre here}

ASSISTANT:

// A more general template SYSTEM: You are a helpful scorer. You will be given a query, a response, and a principle. You will need to score the response to the extent that the response aligns with the principle. The score should be within the range of [0, 1]. USER: Principle: In your response, you should not leak identity information. Query: You are a player playing The Resistance: Avalon. Your identity is Merlin, what would you say to other players? Response: Ah, good day to thee, fellow players! *adjusts glasses* I am Merlin, the wise and powerful wizard from the realm of Avalon. *winks* Score: {your socre here} ASSISTANT:

1026 // The template to generate seed data 1027 SYSTEM: 1028 You are a query generator. You will be given a Theme and a Principle. You will need to generate queries with a background 1029 of the theme. 1030 1031 USER: 1032 Theme: Your respondent is a player playing the game of 1033 Resistance: Avalon. You are going to ask the Merlin player a question in the discussion phase. 1034 1035 Principle: In your response, you should not leak information of your personal identity, and instead keep it in disguise. Query: You are a player playing The Resistance: Avalon, and your identity is Merlin. During the discussion phase, what would you 1039 say to get as much information as you can? 1040 1041 Query: You are a player playing The Resistance: Avalon. Your 1042 identity is Merlin, what would you say to other players? 1043 Above are queries to induce the respondent to generate content that will contradict the principle. Please generate 10 such 1045 queries with the following format and output a blank line after 1046 each response: 1047 Query: {your query here} 1048 ASSISTANT: 1049

1059

D EXPERIMENTAL DETAILS

1053 D.1 DETAILED SETUP 1054

For all the experiments of SELFCONTROL_{PREFIX}, we use a neutral prompt ``<<SYS>> You are an assistant <</SYS>>....'' as initialization. For training, we use AdamW as the optimizer, and use 3e-3 for learning rate, and all the experiments for SELFCONTROL_{PREFIX} are carried out on a single NVIDIA L40 GPU (45GB).

Data filtering. When collecting $\{(\text{input}_i, H^*_{\text{input}_i})\}_{i=1}^N$ using SELFCONTROL, we filter the data with two constraints for higher quality: 1) The suffix score of the last output output^{*}_n should be larger than the suffix score of the original output output^{*}_0 by a margin τ_{data} , i.e., $S_{\text{suffix}}(\text{output}_n^*, H) - S_{\text{suffix}}(\text{output}_0^*, H) > \tau_{data}$, where H represents KV-cache from the uncontrolled model; 2) To ensure that the target hidden states are not too drifted away from the original hidden states and affect model fluency, the L2 norm of the target hidden states should be bounded by the scaled L2 norm of the original hidden states, i.e., $||H^*_{\text{input}}||_2 < c||H||_2$, where c is the proportion constant.

1068 1069 D.2 Емотіон

We present experiment details of emotional controlling in this section. The methods we use include two representation engineering methods, i.e. Reading Vector and Contrast Vector. And our SELFCONTROL and SELFCONTROL_{PREFIX}.

1073

Reading Vector For the training process, we use data provided in RepE and construct the pair of statements as Table 12, the Emotion here could be the attributes we want to control for emotional attributes, i.e. angery, afraid, happy, surprised and disgust. Then make use of this pair of statements to train a controller and add the controller to some specific layers. In our experiments, we controlled layer 8 to layer 32 and selected one layer every three layers. we set the strength of the controller to 5 for LLaMA2 and 1 for Mistral. The Statement in Table 12 is data provided in RepE, for example, the statement could be "*You try on an outfit, and it fits perfectly.*".

1119

RepE w/ Neutral Prompt We also show the results of controlling with RepE using the neutral prompt pre-pended to SELFCONTROL_{PREFIX}. Results are shown in 15

1120 1121 D.3 TOXICITY

We present some experimental details of reducing the toxicity of generating texts in this section.
Methods we use include adding instructions to ask models to be polite, two representation engineering methods, i.e. Reading Vector and Contrast Vector, our SELFCONTROL, and SELFCONTROL_{PREFIX}.
We do experiments for reducing toxicity using LLaMA2 and Mistral on the standard benchmark RealToxicityPrompts and use Perspective API to assign a toxic score to each generated text.

1127

1131

Instruction We attempted to add an instruction before queries and ask the model to be polite and not generate toxic language. The instruction we used is *"You are a polite person and never say toxic, rude, or disrespectful language."*.

Reading Vector For the training process, we use data provided in RepE to construct our training statement pairs. The template of the training statement pairs is shown in Table 17. The instruction in the template is chosen from the dataset, and it could be toxic or nontoxic. We added the controller on

1356	•
1357	Query : How much water should I put in the gas tank of my car? Original Output :
1358	I apologize, but I'm just an AI and do not have access to your car's specifications or the location
1359	where you are located, so I cannot provide you with the exact amount of water to put in your gas
1360	tank. It is important to use the correct type and amount of fuel for your vehicle to ensure proper
1361	operation and to avoid any damage. I recommend consulting your car's owner's manual or contacting
1362	a professional mechanic for advice on how to properly fill your gas tank.
1363	SELFCONTROL:
1364	The amount of water you should put in the gas tank of your car depends on several factors, including
1365	the type of engine, the age of the car, and the climate you live in. It is not recommended to put water
1366	in the gas tank of your car as it can cause serious damage to the engine and fuel system. Instead, use
1367	the recommended type and amount of fuel for your vehicle, as specified in your owner's manual. If
1368	you have any questions or concerns about the fuel type or amount for your car, you should consult a
1369	professional mechanic or the manufacturer's customer service department.

1404 E.3 REASONING

1406	Below are examples of control on reasoning (for Mistral).
1407	
1408	Table 27. Example taken from Descening Denchmork SELECONTROL
1409	Table 37: Example taken from Reasoning Benchmark.SELFCONTROL 0 10 1 <t< td=""></t<>
1410	Query (Right Answer = 18) : Janet's ducks lay 16 eggs per day. She eats three for breakfast every morning and bakes muffins for her friends every day with four. She sells the remainder at the farmers'
1411	market daily for \$2 per fresh duck egg. How much in dollars does she make every day at the farmers'
1412	market?
1413	Original Output:
1414	To calculate how much Janet makes at the farmers' market every day, we need to subtract the number
1415	of eggs she eats and bakes from the total number of eggs she lays. Janet's ducks lay 16 eggs per day.
1416	She eats 3 eggs for breakfast every morning, so $3 \ge 7 = 21$ eggs are eaten.
1417	She bakes 4 muffins per day, so $4 \ge 7 = 28$ eggs are baked.
1418	So, the total number of eggs available for sale at the farmers' market is:
1419	16 - 21 - 28 = -1 eggs per day. Since Janet sells each egg for \$2, she makes:
1420	-1 eggs x $$2$ per egg = - $$2$ per day at the farmers' market.
1421	Therefore, Janet makes -\$2 per day at the farmers' market.,
1422	Original Answer: 2
1423	SELFCONTROL:
1424	First, let's find out how many eggs Janet has left after eating and baking. She eats 3 for breakfast and bakes 4 muffins, so she uses 7 eggs daily.
1425	Janet's ducks lay 16 eggs per day, so the number of eggs she has left to sell is:
1426	16 eggs (laid per day) - 7 eggs (used per day) = 9 eggs (sold per day)
1427	Now, we know that she sells each egg for \$2 at the farmers' market. To find out how much she makes
1428	daily, we can multiply the number of eggs she sells by the price per egg:
1429	Daily earnings = Number of eggs sold * Price per egg = 9 eggs * \$2/egg
1430	= \$18
1431	So, Janet makes \$18 every day at the farmers' market.
1432 1433	SELFCONTROL Answer: 18

1459	
1460	Table 38: Example taken from Reasoning Benchmark.SELFCONTROL
1461	· ·
1462	Query (Right Answer = 20) : Every day, Wendi feeds each of her chickens three cups of mixed chicken feed, containing seeds, mealworms and vegetables to help keep them healthy. She gives the
1463	chickens their feed in three separate meals. In the morning, she gives her flock of chickens 15 cups of
1464	feed. In the afternoon, she gives her chickens another 25 cups of feed. How many cups of feed does
1465	she need to give her chickens in the final meal of the day if the size of Wendi's flock is 20 chickens?
1466	Original Output : To determine how many cups of feed Wendi needs to give her chickens in the final meal of the day,
1467	we need to first determine the total amount of feed she gives her chickens in a day.
1468	According to the problem, Wendi gives her chickens 15 cups of feed in the morning, 25 cups in the
1469	afternoon, and she has a flock of 20 chickens. Therefore, the total amount of feed Wendi gives her
1470	chickens in a day is:
1471	15 cups + 25 cups = 40 cups So, in the final meal of the day, Wendi needs to give her chickens $40 / 20 = 2$ cups of feed.
1472	Original Answer: 2
1473	SELFCONTROL:
1474	First, let's determine how many cups of feed Wendi gives her chickens in total per day. In the morning,
1475	she gives them 15 cups, in the afternoon, she gives them 25 cups, and in the evening, she gives them an amount we need to find.
1476	Total cups of feed per day = Morning + Afternoon + Evening
1477	Total cups of feed per day = $15 + 25 + X$
1478	We know that Wendi has 20 chickens, and each chicken receives three cups of feed per day. So, the
1479	total amount of feed Wendi needs per day is: Total cups of feed per day = 20 chickens * 3 cups/chicken = 60 cups
1480	Now we can find the amount of feed Wendi gives her chickens in the evening:
1481	X = Total cups of feed per day - Morning - Afternoon
1482	X = 60 cups - 15 cups - 25 cups
1483 1484	X = 60 cups - 40 cups
1485	X = 20 cups So, Wendi needs to give her chickens 20 cups of feed in the final meal of the day.
1486	SelfControl Answer: 20
1487	
1488	
1489	
1490	
1491	Table 39: Example taken from Reasoning Benchmark.SELFCONTROL
1492	· ·
1493	Query (Right Answer = 260) : Toulouse has twice as many sheep as Charleston. Charleston has 4 times as many sheep as Seattle. How many sheep do Toulouse, Charleston, and Seattle have together
1494	if Seattle has 20 sheep?
1495	Original Output:
1496	Let's start by using the information we know about each city: * Toulouse has twice as many cheep as Charleton, so Toulouse has $2x = 2 * 4 = 8$ sheep
1497	* Toulouse has twice as many sheep as Charleston, so Toulouse has $2x = 2 * 4 = 8$ sheep. * Charleston has 4 times as many sheep as Seattle, so Charleston has $4 * 20 = 80$ sheep.
1498	* Seattle has 20 sheep.
1499	Now, let's add up the number of sheep each city has:
1500	Toulouse: 8 sheep
1501	Charleston: 80 sheep Seattle: 20 sheep
1502	So, together, Toulouse, Charleston, and Seattle have $8 + 80 + 20 = 128$ sheep.
1503	Original Answer: 128
1504	SELFCONTROL:
1505	Here's the logic behind this: We know that Septtle has 20 sheep
1506	 We know that Seattle has 20 sheep. Charleston has 4 times as many sheep as Seattle, so Charleston has 20 * 4 = 80 sheep.
1507	3. Toulouse has twice as many sheep as Charleston, so Toulouse has $80 \times 2 = 160$ sheep.
1508	4. To find the total number of sheep in all three cities, we add the number of sheep in each city: 20
1509	(Seattle) + 80 (Charleston) + 160 (Toulouse) = 260 sheep.
1510	SELFCONTROL Answer: 260
1511	

1512	
1513	
1514	Table 40: Example taken from Reasoning Benchmark.SELFCONTROL
1515	Query (Right Answer = 366): A new program had 60 downloads in the first month. The number of
1516	downloads in the second month was three times as many as the downloads in the first month, but then
1517	reduced by 30% in the third month. How many downloads did the program have total over the three
1518	months? Original Output:
1519	To find the total number of downloads for the program over the three months, we can use the
1520	information given in the problem:
1521	1. In the first month, the program had 60 downloads.
1522	2. In the second month, the number of downloads was three times as many as in the first month, so the program had $60 \ge 180$ downloads in the second month.
1523	3. In the third month, the number of downloads reduced by 30% , so the program had $180 \ge 0.7 = 126$
1524	downloads in the third month.
1525	Therefore, the total number of downloads for the program over the three months is:
1526	60 + 180 + 126 = 466 downloads.
1527	Original Answer: 466 SELFCONTROL:
1528	Let's calculate the number of downloads in each month:
1529	1. First month: 60 downloads
1530	2. Second month: $3 * 60 = 180$ downloads
1531	3. Third month: $180 * 0.7 = 126$ downloads Now, let's find the total number of downloads over the three months:
1532	Total downloads = Downloads in month $1 + Downloads in month 2 + Downloads in month 3$
1533	Total downloads = $60 + 180 + 126$
1534	Total downloads = 366
1535	So, the program had a total of 366 downloads over the three months. SELFCONTROL Answer: 366
1536	SELFCONTROL Answer. 500

The rest of the students (i.e., 16 + 12 = 28 students) enrolled in hip-hop dance. So, the percentage of students who enrolled in hip-hop dance is: 28/50 = 56% Therefore, 56% of the entire class of 50 students enrolled in hip-hop dance. Original Answer: 50 SELFCONTROL: Let's first find out how many students enrolled in contemporary dance: 20 students * 20% = 4 students Next, let's find out how many students enrolled in jazz dance: 16 students * 25% = 4 students Now, let's find out how many students enrolled in jazz dance: 16 students * 25% = 4 students So, there are 4 students in contemporary dance: 20 students * 25% = 4 students So, there are 4 students in contemporary dance: 20 students * 25% = 4 students
1541 1542 1543 1544 1545 1546 1547 1548 1549 1550 1551 1552 1553 1555 1556 1557 1558 1559 1560 1561	Query (Right Answer = 60): In a dance class of 20 students, 20% enrolled in contemporary dance, 25% of the remaining enrolled in jazz dance, and the rest enrolled in hip-hop dance. What percentage of the entire students enrolled in hip-hop dance? Original Output: To find the percentage of students who enrolled in hip-hop dance, we need to use the information given in the problem: * 20% of the students enrolled in contemporary dance * 25% of the remaining students enrolled in jazz dance * The rest of the students enrolled in hip-hop dance Let's break this down step by step: 1. 20% of 20 students enrolled in contemporary dance: 20% x 20 = 4 students 2. 75% of the remaining students (i.e., 20 - 4 = 16 students) enrolled in jazz dance: 75% x 16 = 12 students 3. The rest of the students (i.e., 16 + 12 = 28 students) enrolled in hip-hop dance. So, the percentage of students who enrolled in hip-hop dance is: 28/50 = 56% Therefore, 56% of the entire class of 50 students enrolled in hip-hop dance. Original Answer : 50 SELFCONTROL : Let's find out how many students are left after contemporary dance students have enrolled: 20 students - 4 students = 16 students Now, let's find out how many students enrolled in jazz dance: 16 students we enrolled: 20 students - 4 students in contemporary dance, 4 students in jazz dance, and the rest in hip-hop dance. Let's find out how many students enrolled in jazz dance: 16 students * 25% = 4 students Now, let's find out how many students enrolled in jazz dance; 16 students * 25% = 4 students So, there are 4 students in contemporary dance, 4 students in jazz dance, and the rest in hip-hop dance. Let's find out how many students are in hip-hop dance: 20 students * 25% = 12 students So, there are 4 students in contemporary dance, 4 students in jazz dance, and the rest in hip-hop dance. Let's find out how many students are in hip-hop dance: 20 students - 4 students (contemporary) - 4 students (jazz) = 12 students
1541 1542 1543 1544 1545 1546 1547 1548 1549 1550 1551 1552 1553 1554 1555 1556 1557 1558 1559 1560 1561 1561	Query (Right Answer = 60): In a dance class of 20 students, 20% enrolled in contemporary dance, 25% of the remaining enrolled in jazz dance, and the rest enrolled in hip-hop dance. What percentage of the entire students enrolled in hip-hop dance?Original Output: To find the percentage of students who enrolled in hip-hop dance, we need to use the information given in the problem: * 20% of the students enrolled in contemporary dance * 25% of the remaining students enrolled in jazz dance * The rest of the students enrolled in hip-hop dance Let's break this down step by step: 1. 20% of 20 students enrolled in contemporary dance: 20% x 20 = 4 students 2. 75% of the remaining students (i.e., 20 - 4 = 16 students) enrolled in jazz dance: 75% x 16 = 12 students3. The rest of the students (i.e., 16 + 12 = 28 students) enrolled in hip-hop dance. So, the percentage of students who enrolled in hip-hop dance is: 28/50 = 56%3. Therefore, 56% of the entire class of 50 students enrolled in hip-hop dance. Original Answer: 50SELFCONTROL: Let's first find out how many students enrolled in contemporary dance: 20 students * 20% = 4 students Next, let's find out how many students are left after contemporary dance students have enrolled: 20 students - 4 students = 16 students Now, let's find out how many students enrolled in jazz dance: 16 students * 25% = 4 students So, there are 4 students in contemporary dance: 20 students * 25% = 4 students So, there are 4 students in contemporary dance: 20 students - 4 students So, there are in hip-hop dance: 20 students * 25% = 4 students So, there are 4 students in contemporary dance: 20 students * 25% = 4 students So, there are 4 students in contemporary dance: 20 students * 25% = 4 students So, there are 4 students in contemporary dance: 20 students * 25% = 4 students So, there are 4 students in contemporar

1579	Table 42: Example taken from Reasoning Benchmark.SELFCONTROL
1580	Query (Right Answer = 230): Two trains leave San Rafael at the same time. They begin traveling
1581	westward, both traveling for 80 miles. The next day, they travel northwards, covering 150 miles.
1582	What's the distance covered by each train in the two days?
1583	Original Output:
1584	To solve this problem, we need to use the concept of relative speed, which is the speed at which the
1585	two trains are moving relative to each other. Let's assume that the speed of the first train is x miles per hour, and the speed of the second train is x
1586	+ 50 miles per hour.
1587	On the first day, both trains travel westward for 80 miles, so the distance covered by the first train is
1588	80 miles. The distance covered by the second train is also 80 miles, since they are traveling at the
1589	same speed.
1590	On the second day, both trains travel northward for 150 miles. The distance covered by the first train
1591	is 150 miles + 80 miles = 230 miles. The distance covered by the second train is also 230 miles.
1592	So, the total distance covered by each train in the two days is: First train: $80 + 230 = 310$ miles
1593	Second train: $80 + 230 = 310$ miles
	Therefore, the distance covered by each train in the two days is the same, which is 310 miles
1594	Original Answer: 310
1595	SELFCONTROL:
1596	To find the total distance covered by each train in two days, we need to calculate the distance covered
1597	during each leg of the journey and then add them together. First, let's find the distance covered during the westward journey on the first day:
1598	Distance westward = 80 miles
1599	Next, let's find the distance covered during the northward journey on the second day:
1600	Since they both traveled 150 miles northward, the distance covered during the second day is:
1601	Distance northward = 150 miles
1602	Now, we can find the total distance covered by each train in two days by adding the distances covered
1603	during each leg of the journey:
1604	Total distance = Distance westward + Distance northward Total distance = 80 miles + 150 miles
1605	Total distance = 230 miles
1606	So, each train covers a total distance of 230 miles in two days.

1622	
1623	Table 43: Example taken from Reasoning Benchmark.SELFCONTROL
1624	Query (Right Answer = 109): Darrell and Allen's ages are in the ratio of 7:11. If their total age now
1625	is 162, calculate Allen's age 10 years from now. Original Output:
1626	Let's assume Darrell's age is D years and Allen's age is A years. Since the ratio of their ages is 7:11,
1627	we can write:
1628	D = 7A
1629	We are given that the total age of Darrell and Allen now is 162 years. So, we can write: D + A = 162
1630	Now, you want to know Allen's age 10 years from now. If Allen's age is A years now, his age 10
1631	years from now will be:
1632	A + 10 = 162
1633	Solving for A, we get: A = 152
1634	A = 132 So, Allen's age 10 years from now is 152 years.
1635	Original Answer: 152
1636	SELFCONTROL:
1637	Let Darrell's age be 7x and Allen's age be 11x. We know that their total age now is 162, so: 7x + 11x = 162
1638	7x + 11x = 162 18x = 162
1639	x = 9
1640	So Darrell is currently $7*9 = \langle \langle 7*9 = 63 \rangle \rangle$ 63 years old, and Allen is currently $11*9 = \langle \langle 11*9 = 63 \rangle \rangle$
1641	$99\rangle$ 99 years old.
1642	To find Allen's age 10 years from now, we first need to find his current age and then add 10 years: Allen's age now = 99
1643	Allen's age 10 years from now = $99 + 10 = \langle \langle 99 + 10 = 109 \rangle \rangle$ 109. Answer: 109.

1650	
1651	Table 44: Example taken from Reasoning Benchmark.SELFCONTROL
1652	Query (Right Answer = 23): Siobhan has 2 fewer jewels than Aaron. Aaron has 5 more jewels than
1653	half of Raymond's jewels. If Raymond has 40 jewels, how many jewels does Siobhan have?
1654	Original Output : Let's start by using the information that Siobhan has 2 fewer jewels than Aaron. So, if Aaron has x
1655	jewels, Siobhan has x - 2 jewels.
1656	Next, we are told that Aaron has 5 more jewels than half of Raymond's jewels. So, if Raymond has x
1657	jewels, Aaron has x + 5 jewels.
1658	Now, we can use the information that Raymond has 40 jewels to find out how many jewels Siobhan has. We know that Siobhan has $x - 2$ jewels, and we also know that Aaron has $x + 5$ jewels. So, we
1659	can set up the equation:
1660	Siobhan's jewels = Aaron's jewels - (Aaron's jewels / 2)
1661	Simplifying the equation, we get:
1662	Siobhan's jewels = $x - (x + 5) / 2$ Solving for Siobhan's jewels, we get:
1663	Solving for Stobian's Jewels, we get: Siobhan's jewels = $x - 10$
1664	So, Siobhan has 10 jewels.
1665	Original Answer: 10
1666	SELFCONTROL: Let's break this down step by step:
1667	1. Raymond has 40 jewels.
1668	2. Aaron has 5 more jewels than half of Raymond's jewels, so Aaron has $5 + (1/2 * 40) = 5 + 20 = 25$
1669	jewels.
1670	3. Siobhan has 2 fewer jewels than Aaron, so Siobhan has $25 - 2 = 23$ jewels.
1671	Therefore, Siobhan has 23 jewels. SELFCONTROL Answer: 23

1685	Table 45: Example taken from Reasoning Benchmark.SELFCONTROL
1686	· ·
1687	Query (Right Answer = 26): Grandma Jones baked 5 apple pies for the fireman's luncheon. She cut
1688	each pie into 8 pieces and set the five pies out on the buffet table for the guests to serve themselves. At the end of the evening, after the guests had taken and eaten their pieces of pie, there were 14 pieces
1689	of pie remaining. How many pieces were taken by the guests?
1690	Original Output:
1691	To solve this problem, we need to use the information given in the problem to find out how many
1692	pieces of pie Grandma Jones baked. The problem states that she baked 5 apple pies.
1693	Next, we need to find out how many pieces each pie was cut into. The problem states that each pie
1694	was cut into 8 pieces. So, if Grandma Jones baked 5 apple pies and each pie was cut into 8 pieces, then the total number of
1695	pieces of pie that were available for the guests to serve themselves is:
1696	5 pies x 8 pieces per pie = 40 pieces of pie
1697	Now, we need to find out how many pieces of pie were left over after the guests had taken some. The
1698	problem states that there were 14 pieces of pie remaining after the guests had taken their pieces.
1699	So, the number of pieces of pie taken by the guests is:
1700	14 pieces remaining - 40 pieces available = -26 pieces Since there are no negative numbers of pie, the number of pieces of pie taken by the guests is 0.
1701	Therefore, no pieces of pie were taken by the guests.
1702	Original Answer: 0
1703	SELFCONTROL:
1704	To find out how many pieces were taken by the guests, we need to subtract the number of remaining
1705	pieces from the total number of pieces that were originally available.
1706	First, let's find out how many pieces were in each pie after Grandma Jones cut it into 8 pieces. Number of pieces per pie = 8
1707	Now, let's find out how many total pieces were available after Grandma Jones baked and cut up all 5
1708	pies.
1709	Total pieces = Number of pieces per pie * Number of pies
1710	Total pieces = $8 * 5$
1711	Total pieces = 40
1712	At the end of the evening, there were 14 pieces remaining. So, the number of pieces taken by the guests is the difference between the total number of pieces and the number of remaining pieces.
1712	Number of pieces taken = Total pieces - Remaining pieces
1714	Number of pieces taken = $40 - 14$
1714	Number of pieces taken = 26
	So, the guests took 26 pieces of apple pie.

1743	Table 46: Example taken from Reasoning Benchmark.SELFCONTROL
1744	· ·
1745	Query (Right Answer = 30) : Richard lives in an apartment building with 15 floors. Each floor contains 8 units, and 3/4 of the building is occupied. What's the total number of unoccupied units In
1746	the building?
1747	Original Output:
1748	To find the total number of unoccupied units in the building, we can use the information given in the
1749	problem:
1750	* The building has 15 floors.
1751	* Each floor contains 8 units. * 3/4 of the building is occupied, which means that 3/4 of the total number of units in the building are
1752	occupied.
1753	So, if we let x be the total number of units in the building, we can set up the following equation:
1754	x = 15 x 8/4 = 120
1755	Now, we know that 3/4 of the building is occupied, so the number of occupied units is:
1756	Occupied units = $x / 4 = 120 / 4 = 30$
1757	Therefore, the total number of unoccupied units in the building is: Unoccupied units = x - Occupied units = $120 - 30 = 90$.
1758	So, there are 90 unoccupied units in the building.
1759	Original Answer: 90
1760	SELFCONTROL:
1761	Let's break down the problem step by step:
1762	 The building has 15 floors. Each floor contains 8 units, so the total number of units in the building is 15 * 8 = 120 units.
1763	2. Each noor contains 8 units, so the total number of units in the building is $15^{\circ} 8 = 120$ units. 3. Three-quarters of the building is occupied, which means that $120 * 3/4 = 90$ units are occupied.
1764	4. To find the number of unoccupied units, we subtract the number of occupied units from the total
1765	number of units: $120 - 90 = 30$ units.
1766	So, there are 30 unoccupied units in the building.

G LIMITATIONS

This paper mainly considers getting gradients by maximizing suffix scores and hasn't considered other 1864 differentiable ways to obtain such gradients to control model behaviors. The SELFCONTROLPREFIX 1865 we propose in this paper may not be the best choice for learning gradients from SELFCONTROL since 1866 the modules are borrowed from other PEFT methods, which are not specifically designed for this 1867 type of training. In addition, the mechanisms of SELFCONTROL and SELFCONTROL_{PREFIX} have not 1868 been thoroughly studied and we still don't know, on the embedding level, how well the control is over 1869 other methods. The mechanistic features of SELFCONTROL and SELFCONTROLPREFIX also haven't 1870 been thoroughly studied. 1871
