Contextualization Distillation from Large Language Model for Knowledge Graph Completion

Anonymous ACL submission

Abstract

 While textual information significantly en- hances the performance of pre-trained language models (PLMs) in knowledge graph comple- tion (KGC), the static and noisy nature of exist- ing corpora collected from Wikipedia articles or synsets definitions often limits the poten- tial of PLM-based KGC models. To surmount these challenges, we introduce the *Contextual- ization Distillation* strategy, a versatile plug-in- and-play approach compatible with both dis- criminative and generative KGC frameworks. **Our method begins by instructing large lan-** guage models (LLMs) to transform compact, structural triplets into context-rich segments. **Subsequently, we introduce two tailored aux-iliary tasks—reconstruction and contextualiza-**017 tion—allowing smaller KGC models to assimi- late insights from these enriched triplets. Com- prehensive evaluations across diverse datasets and KGC techniques highlight the efficacy and adaptability of our approach, revealing consis- tent performance enhancements irrespective of underlying pipelines or architectures. More- over, our analysis makes our method more ex- plainable and provides insight into how to gen- erate high-quality corpora for KGC, as well as the selection of suitable distillation tasks.

028 1 Introduction

 Knowledge graph completion (KGC) is a funda- mental task in natural language processing (NLP), aiming at unveiling hidden insights within diverse knowledge graphs to explore novel knowledge pat- terns. Traditional KGC methods [\(Nickel et al.,](#page-9-0) [2011;](#page-9-0) [Bordes et al.,](#page-8-0) [2013\)](#page-8-0) typically predict the missing part of the triplets by learning the repre- sentation of each entity and relation based on their structural information. However, such embedding- based methods tend to overlook the rich textual in- formation of the knowledge graph. Therefore, pre- trained language models (PLMs) have been intro- [d](#page-9-1)uced to KGC and achieved promising results [\(Ken-](#page-9-1)[ton and Toutanova,](#page-9-1) [2019;](#page-9-1) [Xie et al.,](#page-10-0) [2022\)](#page-10-0).

Figure 1: An example to illustrate the limitations of the current textual information for KGC.

Methods	H@1	H@3	H@8/10
ChatGPT-1-shot	15.6	17.6	19.6
PaLM2-1-shot	15.7	20.8	25.4
KG-S2S (Chen et al., 2022a)	28.5	38.8	49.3

Table 1: ChatGPT and PaLM2's unsatisfactory performance on the test set of FB15k-237N compared to a smaller KGC model, KG-S2S [\(Chen et al.,](#page-8-1) [2022a\)](#page-8-1).

While it has been well-discovered that textual **043** information can be beneficial for PLM-based KGC **044** [m](#page-8-1)odels [\(Yao et al.,](#page-10-1) [2019;](#page-10-1) [Wang et al.,](#page-10-2) [2021b;](#page-10-2) [Chen](#page-8-1) **045** [et al.,](#page-8-1) [2022a,](#page-8-1) [2023a\)](#page-8-2), prior attempts to augment **046** KGC models with textual data from Wikipedia arti- **047** [c](#page-10-1)le [\(Zhong et al.,](#page-10-3) [2015\)](#page-10-3) or synsets definitions [\(Yao](#page-10-1) **048** [et al.,](#page-10-1) [2019\)](#page-10-1) have encountered certain limitations: **049** (*i*) Entity descriptions, often succinct and static, **050** may inhibit the formation of a comprehensive un- **051** derstanding of entities within KGC models. (*ii*) **052** The incorporation of triplet descriptions, albeit po- **053** tentially enriching, can introduce substantial noise, **054** particularly when derived through automatic entity **055** alignment [\(Sun et al.,](#page-9-2) [2020\)](#page-9-2). Figure [1](#page-0-0) demonstrates **056** an example to illustrate the aforementioned limita- **057** tions. The description for the head "*J. G. Ballard*" **058** is limited and for the tail "*Shanghai*", it mistakenly **059** uses the definition of the movie also named "Shang- **060** hai". Also, while the two entities show up in the $\qquad \qquad 061$ triplet description, it falls short in conveying the **062** semantic essence of the relation "*place_of_birth*". **063**

In light of these limitations, our attention shifts **064** to Large Language Models (LLMs) [\(Brown et al.,](#page-8-3) **065** [2020;](#page-8-3) [Zhang et al.,](#page-10-4) [2022;](#page-10-4) [Anil et al.,](#page-8-4) [2023;](#page-8-4) [Touvron](#page-10-5) **066**

 [et al.,](#page-10-5) [2023\)](#page-10-5), renowned for their capability in gen- erating articulate and high-quality data [\(Dai et al.,](#page-8-5) [2023;](#page-8-5) [Shridhar et al.,](#page-9-3) [2023;](#page-9-3) [Zheng et al.,](#page-10-6) [2023\)](#page-10-6). Our exploration commences with a scrupulous evalu- ation of LLMs, such as ChatGPT and PaLM2, in KGC, benchmarking them across several esteemed [K](#page-8-7)GC datasets [\(Dettmers et al.,](#page-8-6) [2018;](#page-8-6) [Garcia-Duran](#page-8-7) [et al.,](#page-8-7) [2018;](#page-8-7) [Mahdisoltani et al.,](#page-9-4) [2013\)](#page-9-4). Utiliz- ing 1-shot In-Context Learning (ICL), we deduce missing heads or tails in triplets and report evalu- ation metrics. It reveals a significant performance discrepancy of two LLMs in comparison to KG- S2S [\(Chen et al.,](#page-8-1) [2022a\)](#page-8-1) despite its reliance on a smaller foundational model, T5-base [\(Raffel et al.,](#page-9-5) [2020\)](#page-9-5). This insight propels us toward the conclu- sion that direct utilization of LLMs for KGC tasks, while intuitive, is outperformed by the fine-tuning of more diminutive, specialized KGC models. This observation aligns with findings from [\(Liang et al.,](#page-9-6) [2022;](#page-9-6) [Sun et al.,](#page-9-7) [2023;](#page-9-7) [Zhao et al.,](#page-10-7) [2023\)](#page-10-7), which highlighted the limitations of LLMs in knowledge- centric tasks. Experiment results and analysis on more KGC datasets can be found in Appendix [A.](#page-12-0)

 To optimally harness LLMs for KGC, we draw inspiration from recent works [\(Xiang et al.,](#page-10-8) [2022;](#page-10-8) [Kim et al.,](#page-9-8) [2022a\)](#page-9-8) and introduce a novel approach, *Contextualization Distillation*. Contextualization Distillation first extracts descriptive contexts from LLMs with well-designed prompts, thereby se- curing dynamic, high-quality context for each en- tity and triplet. Subsequent to this, two auxiliary tasks are proposed to train smaller KGC models with these informative, descriptive contexts. The plug-in-and-play characteristic of our contextual- ization distillation enables us to apply and evaluate it on various KGC datasets and baseline models. Through extensive experiments, we affirm that Con- textualization Distillation consistently enhances the performance of smaller KGC models, irrespective of architectural and pipeline disparities. Addition- ally, we provide an exhaustive analysis of each step of Contextualization Distillation, encouraging further insights and elucidations.

110 The contributions of this work can be summa-**111** rized into three main aspects:

 • We identify the constraints of the current cor- pus for PLMs-based KGC models and intro- duce a plug-in-and-play approach, Contextual- ization Distillation, to enhance smaller KGC models with extracted rationale from LLMs.

117 • We conduct extensive experiments across sev-

experiments, we validate the effectiveness of **120** Contextualization Distillation in consistently **121** improving smaller KGC models. **122** • We delve into a comprehensive analysis of **123** our proposed method and provide valuable **124** insights and guidance on how to generate high- **125** quality corpora for distillation, as well as the **126** selection of suitable distillation tasks. **127** 2 Related Work **¹²⁸** 2.1 Knowledge Graph Completion **129** [T](#page-8-0)raditional KGC methods [\(Nickel et al.,](#page-9-0) [2011;](#page-9-0) [Bor-](#page-8-0) **130** [des et al.,](#page-8-0) [2013\)](#page-8-0) involve embedding entities and **131** relations into a representation space. In pursuit of a **132** more accurate depiction of entity-relation pairs, dif- **133** ferent representation spaces [\(Trouillon et al.,](#page-10-9) [2016;](#page-10-9) **134** [Xiao et al.,](#page-10-10) [2016\)](#page-10-10) have been proposed considering **135** various factors, e.g., differentiability and calcula- **136** tion possibility [\(Ji et al.,](#page-9-9) [2021\)](#page-9-9). During training, **137** two primary objectives emerge to assign higher **138** scores to true triplets than negative ones: 1) Translational distance methods gauge the plausibility of **140** a fact by measuring the distance between the two **141** entities under certain relations [\(Lin et al.,](#page-9-10) [2015;](#page-9-10) 142 [Wang et al.,](#page-10-11) [2014\)](#page-10-11); 2) Semantic matching meth- **143** ods compute the latent semantics of entities and **144** relations [\(Yang et al.,](#page-10-12) [2015;](#page-10-12) [Dettmers et al.,](#page-8-6) [2018\)](#page-8-6). **145**

eral widely recognized KGC datasets and uti- **118** lize various baseline models. Through these **119**

To better utilize the rich textual information of **146** knowledge graphs, PLMs have been introduced **147** in KGC. [Yao et al.](#page-10-1) [\(2019\)](#page-10-1) first propose to use **148** BERT [\(Kenton and Toutanova,](#page-9-1) [2019\)](#page-9-1) to encode the **149** entity and relation's name and adopt a binary classi- **150** fier to predict the validity of given triplets. Follow- **151** ing them, [Wang et al.](#page-10-13) [\(2021a\)](#page-10-13) leverage the Siamese **152** network to encode the head-relation pair and tail in **153** a triplet separately, aiming to reduce the time cost **154** and make the inference scalable. [Lv et al.](#page-9-11) [\(2022\)](#page-9-11) **155** convert each triple and its textual information into **156** natural prompt sentences to fully inspire PLMs' po- **157** tential in the KGC task. [Chen et al.](#page-8-2) [\(2023a\)](#page-8-2) design **158** a conditional soft prompts framework to maintain a **159** balance between structural information and textual **160** knowledge in KGC. Recently, there are also some **161** works trying to leverage generative PLMs to per- **162** form KGC in a sequence-to-sequence manner and **163** [a](#page-9-12)chieve promising results [\(Xie et al.,](#page-10-0) [2022;](#page-10-0) [Saxena](#page-9-12) **164** [et al.,](#page-9-12) [2022;](#page-9-12) [Chen et al.,](#page-8-1) [2022a\)](#page-8-1). **165**

Figure 2: An overview pipeline of our Contextualization Distillation. We first extract descriptive contexts from LLMs (Section [3.1\)](#page-2-0). Then, two auxiliary tasks, reconstruction (Section [3.2.1\)](#page-3-0) and contextualization (Section [3.2.2\)](#page-3-1) are designed to train the smaller KGC models with the contextualized information.

166 2.2 Distillation from LLMs

 Knowledge distillation has proven to be an effec- tive approach for transferring expertise from larger, highly competent teacher models to smaller, afford170 [a](#page-8-9)ble student models (Buciluǎ et al., [2006;](#page-8-8) [Hinton](#page-8-9) [et al.,](#page-8-9) [2015;](#page-8-9) [Beyer et al.,](#page-8-10) [2022\)](#page-8-10). With the emer- gence of LLMs, a substantial body of research has concentrated on distilling valuable insights from these LLMs to enhance the capabilities of smaller PLMs. One of the most common methods is to prompt LLMs to explain their predictions and then use such rationales to distill their reasoning abil- [i](#page-8-11)ties into smaller models [\(Wang et al.,](#page-10-14) [2022;](#page-10-14) [Ho](#page-8-11) [et al.,](#page-8-11) [2023;](#page-8-11) [Magister et al.,](#page-9-13) [2022;](#page-9-13) [Hsieh et al.,](#page-8-12) [2023;](#page-8-12) [Shridhar et al.,](#page-9-3) [2023\)](#page-9-3). Distilling conversations from LLMs is another cost-effective method to build [n](#page-8-13)ew dialogue datasets [\(Kim et al.,](#page-9-14) [2022b;](#page-9-14) [Chen](#page-8-13) [et al.,](#page-8-13) [2023b;](#page-8-13) [Kim et al.,](#page-9-8) [2022a\)](#page-9-8) or augment existing [o](#page-10-6)nes [\(Chen et al.,](#page-8-14) [2022b;](#page-8-14) [Zhou et al.,](#page-11-0) [2022;](#page-11-0) [Zheng](#page-10-6) [et al.,](#page-10-6) [2023\)](#page-10-6). There are also some attempts [\(Mar-](#page-9-15) [jieh et al.,](#page-9-15) [2023;](#page-9-15) [Zhang et al.,](#page-10-15) [2023\)](#page-10-15) that focus on distilling domain-specific knowledge from LLMs for various downstream applications.

 Several recent studies have validated the con- textualization capability of LLMs to convert struc- tural data into raw text. Among them, [Xiang et al.](#page-10-8) [\(2022\)](#page-10-8) convert triplets in the data-to-text generation dataset into their corresponding descriptions **193** to facilitate disambiguation. [Kim et al.](#page-9-8) [\(2022a\)](#page-9-8) de- **194** sign a pipeline for synthesizing a dialogue dataset **195** by distilling conversations from LLMs, enhanced **196** with a social commonsense knowledge graph. By 197 contrast, we are the first to leverage descriptive con- **198** text generated by LLMs as an informative auxiliary **199** corpus to the KGC models. **200**

3 Contextualization Distillation **²⁰¹**

In this section, we first illustrate how we curate **202** prompts to extract the descriptive context of each **203** triplet from the LLM. Subsequently, we design a **204** multi-task framework, together with two auxiliary **205** tasks—reconstruction and contextualization—to **206** train smaller KGC models with these high-quality **207** context corpus. The overview pipeline of our **208** method is illustrated in Figure [2.](#page-2-1) **209**

3.1 Extract Descriptive Context from LLMs **210**

Recent studies have highlighted the remarkable **211** ability of LLMs to contextualize structural data **212** [a](#page-10-8)nd transform it into context-rich segments [\(Xiang](#page-10-8) **213** [et al.,](#page-10-8) [2022;](#page-10-8) [Kim et al.,](#page-9-8) [2022a\)](#page-9-8). Here we borrow **214** their insights and extract descriptive context from **215** LLMs to address the limitations of the existing **216** KGC corpus we mentioned in Section [1.](#page-0-1) **217**

Figure 3: An example contains our instruction to LLMs and the generated descriptive context. We use green to highlight entity description prompt/ generation result and blue to highlight triplet description prompt/ generation result.

 In particular, we focus on two commonly em- ployed types of descriptions prevalent in prior methodologies: entity description (ED) [\(Yao et al.,](#page-10-1) [2019;](#page-10-1) [Chen et al.,](#page-8-1) [2022a\)](#page-8-1) and triplet description (TD) [\(Sun et al.,](#page-9-2) [2020\)](#page-9-2). Entity description refers to the definition and description of individual entities, while triplet description refers to a textual segment that reflects the specific relationship between two entities within a triplet. Given triplets of a knowl-227 edge graph $t_i \in T$, we first curate prompt p_i for 228 the i^{th} triplet by filling the pre-defined template:

$$
p_i = \text{Template}(h_i, r_i, t_i), \tag{1}
$$

230 where h_i , r_i , t_i are the head entity, relation, and 231 tail entity of the i^{th} triplet. Then, we use p_i as the **232** input to prompt the LLM to generate the descriptive 233 **context** c_i for each triplet:

$$
c_i = \text{LLM}(p_i),\tag{2}
$$

 As Figure [3](#page-3-2) shows, in our Contextualization Dis- tillation, we design the template to generate both entity description and triplet description at one time. The generating path of each descriptive context can 239 be expressed as $T \longrightarrow (ED, TD)$. Without loss of generalization, we conduct an ablation study to adopt different generating paths of auxiliary con-text in Section [4.3.](#page-5-0)

243 3.2 Multi-task Learning with Descriptive **244** Context

 Different PLM-based KGC models adopt diverse loss functions and pipeline architectures [\(Yao et al.,](#page-10-1) [2019;](#page-10-1) [Chen et al.,](#page-8-1) [2022a;](#page-8-1) [Xie et al.,](#page-10-0) [2022;](#page-10-0) [Chen](#page-8-2) [et al.,](#page-8-2) [2023a\)](#page-8-2). To ensure the compatibility of our Contextualization Distillation to be applied in various PLM-based KGC methods, we design a multi-task learning framework for these models to learn from both the KGC task and auxiliary descrip- **252** tive context-based tasks. For the auxiliary tasks, we **253** design *reconstruction* (Section [3.2.1\)](#page-3-0) and *contex-* **254** *tualizatioin* (Section [3.2.2\)](#page-3-1) for discriminative and **255** generative KGC models respectively. **256**

3.2.1 Reconstruction **257**

The reconstruction task aims to train the model to **258** restore the corrupted descriptive contexts. For the **259** discriminative KGC models, we follow the imple- **260** mentation of [Kenton and Toutanova](#page-9-1) [\(2019\)](#page-9-1) and **261** use masked language modeling (MLM). Previous **262** studies have validated that such auxiliary self- **263** supervised tasks in the domain-specific corpus **264** can benefit downstream applications [\(Han et al.,](#page-8-15) **265** [2021;](#page-8-15) [Wang et al.,](#page-10-2) [2021b\)](#page-10-2). **266**

To be specific, MLM randomly identifies 15% of **267** the tokens within the descriptive context. Among **268** these tokens, 80% are tactically concealed with the **269** special token " $\lt Mask \gt$ ", 10% are seamlessly 270 substituted with random tokens, while the remain- **271** ing 10% keep unchanged. For each selected token, **272** the objective of MLM is to restore the original con- **273** tent at that particular position, achieved through **274** the cross-entropy loss. The aforementioned pro- **275** cess can be formally expressed as follows: **276**

$$
c_i' = \text{MLM}(c_i), \tag{3}
$$

278

$$
\mathcal{L}_{rec} = \frac{1}{N} \sum_{i=1}^{N} \ell(f(c_i'), c_i)
$$
 (4) 279

The final loss of discriminative KGC models is **280** the combination of the KGC loss^{[1](#page-3-3)} and the proposed 281 reconstruction loss: **282**

$$
\mathcal{L}_{dis} = \mathcal{L}_{kgc} + \alpha \cdot \mathcal{L}_{rec}, \tag{5}
$$

where α is a hyper-parameter to control the ratios 284 between the two losses. **285**

3.2.2 Contextualization **286**

The objective of contextualization is to instruct **287** the model in generating the descriptive context c_i 288 when provided with the original triplet $t_i = h, r, t$. 289 Compared with reconstruction, contextualization **290** demands a more nuanced and intricate ability **291** from PLM. It necessitates the PLM to precisely **292** grasp the meaning of both entities involved and the **293** inherent relationship that binds them together, to **294** generate fluent and accurate descriptions. **295**

¹We give the illustration of the discriminative KGC models we used in Appendix [B.1](#page-12-1)

-

298
$$
I_i = \text{Con}(h_i, \langle \text{Sep } \rangle, r_i, \langle \text{Sep } \rangle, t_i)
$$
 (6)

299 Then, we input them into the generative PLM and **300** train the model to generate descriptive context c_i **301** using the cross-entropy loss:

302
$$
\mathcal{L}_{con} = \frac{1}{N} \sum_{i=1}^{N} \ell(f(I_i), c_i)
$$
 (7)

303 The final loss of generative KGC models is the 304 combination of the KGC loss^{[2](#page-4-0)} and the proposed **305** contextualization loss:

$$
\mathcal{L}_{gen} = \mathcal{L}_{kgc} + \alpha \cdot \mathcal{L}_{con} \tag{8}
$$

 For generative KGC models, it is also applicable to apply reconstruction as the auxiliary task. We have done an ablation study in Section [4.4](#page-6-0) to ex- amine the effectiveness of each auxiliary task on generative KGC models.

³¹² 4 Experiment

 In this section, we apply our Contextualization Dis- tillation across a range of PLM-based KGC base- lines. We compare our enhanced model with our approach against the vanilla models using several KGC datasets. Additionally, we do further analysis of each component in our contextualized distilla- tion and make our method more explainable by conducting case studies.

321 4.1 Experimental Settings

 Datasets We use WN18RR [\(Dettmers et al.,](#page-8-6) [2018\)](#page-8-6) and FB15k-237N [\(Lv et al.,](#page-9-11) [2022\)](#page-9-11) in our experiment. WN18RR serves as an enhanced ver- [s](#page-8-0)ion of its respective counterparts, WN18 [\(Bordes](#page-8-0) [et al.,](#page-8-0) [2013\)](#page-8-0). The improvements involve the re- moval of all inverse relations to prevent potential data leakage. For FB15K-237N, it's a refine ver- sion of FB15k [\(Bordes et al.,](#page-8-0) [2013\)](#page-8-0), by eliminat- ing concatenated relations stemming from Free- base mediator nodes [\(Akrami et al.,](#page-8-16) [2020\)](#page-8-16) to avoid Cartesian production relation issues.

 Baselines we adopt several PLM-based KGC models as baselines and apply the proposed Contex- [t](#page-10-1)ualization Distillation to them. KG-BERT [\(Yao](#page-10-1) [et al.,](#page-10-1) [2019\)](#page-10-1) is the first to suggest utilizing PLMs

for the KGC task. we also consider CSProm- **337** KG [\(Chen et al.,](#page-8-2) [2023a\)](#page-8-2), which combines PLMs **338** with traditional Knowledge Graph Embedding 339 (KGE) models, achieving a balance between ef- **340** ficiency and performance in KGC. In addition to **341** these discriminative models, we also harness gen- **342** erative KGC models. GenKGC [\(Xie et al.,](#page-10-0) [2022\)](#page-10-0) **343** is the first to accomplish KGC in a sequence-to- **344** [s](#page-9-16)equence manner, with a fine-tuned BART [\(Lewis](#page-9-16) **345** [et al.,](#page-9-16) [2020\)](#page-9-16) as its backbone. Following them, KG- **346** S2S [\(Chen et al.,](#page-8-1) [2022a\)](#page-8-1) adopt soft prompt tuning **347** and lead to a new SOTA performance among the **348** generative KGC models. **349**

Implementation details All our experiments are **350** conducted on a single GPU (RTX A6000), with **351** [C](#page-8-4)UDA version 11.1. We use PaLM2-540B[\(Anil](#page-8-4) **352** [et al.,](#page-8-4) [2023\)](#page-8-4) as the large language model to distill **353** descriptive context. We tune the Contextualization **354** Distillation hyper-parameter $\alpha \in \{0.1, 0.5, 1.0\}$. **355** We follow the hyper-parameter settings in the orig- 356 inal papers to reproduce each baseline's result. For **357** [a](#page-8-1)ll datasets, we follow the previous works [\(Chen](#page-8-1) **358** [et al.,](#page-8-1) [2022a,](#page-8-1) [2023a\)](#page-8-2) and report Mean Reciprocal **359** Rank (MRR), Hits@1, Hits@3 and Hits@10. More **360** details about our experiment implementation and **361** dataset statistics are shown in Appendix [C.](#page-13-1) 362

4.2 Main Result 363

Table [2](#page-5-1) displays the results of our experiments **364** on WN18RR and FB15k-237N. We observe that **365** our Contextualization Distillation consistently en- **366** hances the performance of all baseline methods, 367 regardless of whether they are based on genera- **368** tive or discriminative models. This unwavering **369** improvement demonstrates the robust generaliza- **370** tion and compatibility of our approach across **371** various PLMs-based KGC methods. **372**

Additionally, some baselines we choose to im- **373** plement our Contextualization Distillation also uti- **374** lize context information. For example, both KG- **375** BERT and CSProm-KG adopt entity descriptions **376** to enhance entity embedding representation. Nev- **377** ertheless, our approach manages to deliver addi- **378** tional improvements to these context-based base- **379** lines. Among them, it is worth noting that the **380** application of our approach to KG-BERT achieves **381** an overall 31.7% enhancement in MRR. All these **382** findings lead us to the conclusion that Contextual- **383** ization Distillation is not only compatible with **384** context-based KGC models but also capable of **385** further enhancing their performance. **386**

²⁹⁶ Specifically, we concatenate head, relation and 297 tail with a special token " \lt *Sep* $>$ " as input:

387 4.3 Ablation Study on Generating Path

 We investigate the efficacy of different context types in the distillation process by employing var- ious generative paths. As illustrated in Table [3,](#page-5-2) we initially explore the impact of entity descrip- tion and triplet description when utilized separately **as auxiliary corpora (denoted as** $T \rightarrow ED$ **and** $T \longrightarrow TD$. The experimental findings under- score the critical roles played by both entity de- scription and triplet description as distillation cor- pora, leading to noticeable enhancements in the performance of smaller KGC models. Further- more, we ascertain that our method's generating **path** $T \longrightarrow (ED, TD)$, which utilizes these two corpora, achieves more improvements by endowing

the models with a more comprehensive and richer **402** source of information. **403**

To gain a comprehensive understanding of the **404** effectiveness of our Contextualization Distillation, **405** we also explored other alternative generative paths. **406** While rationale distillation has demonstrated its **407** potential in various NLP tasks [\(Hsieh et al.,](#page-8-12) [2023;](#page-8-12) **408** [Shridhar et al.,](#page-9-3) [2023\)](#page-9-3), our investigation delves into **409** the $T \longrightarrow RA$ path, wherein we instruct the LLM 410 to generate rationales for each training sample^{[3](#page-5-3)}. Although the model utilizing rationale distillation **412** exhibits improved performance compared to the **413** vanilla one, it falls short when compared with our **414** Contextualization Distillation incorporating entity **415** descriptions and triplet descriptions. One plausible **416** explanation for this disparity lies in the intrinsic **417** nature of rationales, which tend to be intricate and **418** structurally complex. This complexity can pose a **419** greater challenge for smaller models to fully com- **420** prehend, in contrast to the more straightforward **421** descriptive text utilized in our approach. **422**

. **411**

Also, we borrow the insight from Chain-of-CoT **423** (CoT) [\(Wei et al.,](#page-10-18) [2022\)](#page-10-18) that generates the content **424** step by step, and conducts the experiment of the **425** generation process $T \longrightarrow ED \longrightarrow TD$. Specifi- 426 cally, we initially prompt the LLM to generate de- **427** scriptions for two entities and subsequently append **428** these entity descriptions to the prompt, instructing **429**

³We give further details and examples of our prompt in Appendix [E](#page-14-0)

Table 4: Ablation study results on GenKGC and KG-S2S with reconstruction and contextualization as the auxiliary task respectively. We conduct the experiment using FB15k-237N.

 the LLM to generate the triplet description. During training, we concatenate the entity description and triplet description to form the auxiliary corpus for smaller KGC models. Interestingly, our findings indicate that this multi-step generative path also yields suboptimal performance when compared to the single-step generative path. This discrepancy can be attributed to the text incoherence resulting from the concatenation of three segments of de- scriptions. In light of the insights gained from these observations, we summarize our distillation guidance for KGC as follows: smaller models can benefit more from comprehensive, descriptive and coherent content generated by LLMs.

444 4.4 Ablation Study on Generative KGC **445** Models

 In this section, we compare the effectiveness of reconstruction and contextualization in generative KGC models. For GenKGC and KG-S2S, we em- ploy the pre-trained tasks of their respective back- bone models (BART for GenKGC and T5 for KG- S2S) as the reconstruction objective. More details of our reconstruction implementation for genera-tive KGC models can be found in Appendix [D.](#page-14-1)

 Table [4](#page-6-1) presents the ablation study results on FB15k-237N. We find reconstruction is also ef- fective in improving the performance of genera- tive KGC models, showing that KGC models can consistently benefit from the descriptive context with different auxiliary tasks. Comparing the two auxiliary tasks, models with contextualization out- perform those with reconstruction on almost ev- ery metric, except for Hits@1 in KG-S2S. This implies that contextualization is a critical capa- bility for generative KGC models to master for better KGC performance. Generative models have benefited more from the training of convert- ing structural triplets into descriptive context than simply restoring the corrupted corpus.

Figure 4: MRR scores on the validation set during the CSProm-KG training on FB15k-237N. We use thin bars to mark the epochs in which the models achieve the best performance in the validation set.

4.5 Efficiency Analysis **469**

The additional training cost brought by the aux- **470** iliary distillation tasks may pose a potential con- **471** straint on our approach. However, we also notice **472** baseline models with our method coverage faster **473** on the validation set. Figure [4](#page-6-2) presents the valida- **474** tion MRR vs epoch numbers during the CSProm- **475** KG training on FB15k-237N. It is obvious that **476** CSProm-KG with Contextualization Distillation **477** achieves a faster convergence and attains the best **478** checkpoint earlier (at around 125 epochs) com- **479** pared to the variant without our method (at around **480** 220 epochs). This implies auxiliary distillation **481** loss can also expedite model learning in KGC. **482** This trade-off between batch processing time and **483** training steps ultimately results in a training effi- **484** ciency comparable to that of the vanilla models. **485**

4.6 Case Study 486

To demonstrate the advantage of our Contextualiza- **487** tion Distillation more directable, we conduct a com- **488** parative analysis between the description corpus **489** collected by [Zhong et al.](#page-10-3) [\(2015\)](#page-10-3) and those gener- **490** ated using our method. As presented in Table [5,](#page-7-0) en- **491** tity descriptions generated by the LLM effectively **492** address the limitations issue and static shortcom- **493** ings, resulting in more informative and accurate **494** content. Regarding the triplet description, although **495** the "semi-autobiographical" used in [Zhong et al.](#page-10-3) **496** [\(2015\)](#page-10-3) somewhat implies J.G. Ballard's connection **497** to Shanghai during his childhood, it still fails to **498** express the semantics of "*place_of_birth*" clearly. **499** In contrast, the descriptive context generated by **500** our method provides a more elaborate and coherent **501**

Wikipedia (Zhong et al., 2015)	Ours
Ballard was a novelist.	J.G. Ballard (1930-2009) was an English

Table 5: Descriptive context of the triplet *(J.G. Ballard, place_of_birth, Shanghai)*. The text in green represents positive content and the text in red represents negative content.

Table 6: Case study on FB15K-237N with KG-S2S. we also let the model generate a descriptive context for each test sample. The text in bold represents informative content in the generated descriptive context.

 contextualization of the "*place_of_birth*" between "*J.G. Ballard*" and "*Shanghai*". These comparisons highlight the effectiveness of our method in ad-dressing the previous corpus' limitation.

 Furthermore, We showcase how the auxiliary training with descriptive context enhances the base- line models. Table [6](#page-7-1) presents the results of KG- S2S performance in a test sample of FB15k-237N, both with and without our contextualization distil- lation. In this case, the vanilla KG-S2S wrongly predicts the genre of the film "*The Devil's Double*" as "'*War film*', whereas the KG-S2S trained with our auxiliary task correctly labels it as "*Biographi-cal film*". Also, by making the model contextualize

each triplet, we find the model with our method **516** applied successfully captures many details about **517** the movie, such as the genre and plot, and presents **518** this information as fluent text. In summary, the **519** model not only acquires valuable insights about **520** the triplets but also gains the ability to adeptly **521** contextualize this information through our Con- **522** textualization Distillation. **523**

5 Conclusion 524

In this work, we propose Contextualization Dis- **525** tillation, addressing the limitation of the existing **526** KGC textual data by prompting LLMs to generate **527** descriptive context. To ensure the versatility of our **528** approach across various PLM-based KGC models, **529** we have designed a multi-task learning framework. **530** Within this framework, we incorporate two aux- **531** iliary tasks, reconstruction and contextualization, **532** which aid in training smaller KGC models in the 533 informative descriptive context. We conduct exper- **534** iments on several mainstream KGC benchmarks **535** and the results show that our Contextualization Dis- **536** tillation consistently enhances the baseline model's **537** performance. Furthermore, we conduct in-depth **538** analyses to make the effect of our method more **539** explainable, providing guidance on how to effec- **540** tively leverage LLMs to improve KGC as well. In **541** the future, we plan to adapt our method to other **542** knowledge-driven tasks, such as entity linking and **543** knowledge graph question answering. **544**

⁵⁴⁵ 6 Limitation

 One limitation of our approach is that the descrip- tive context extraction stage is only tested with the PaLM2 model due to its unlimited API. The behavior of other LLMs of varying sizes in gen- erating auxiliary corpora for KGC remains unex- plored. Due to limitations in computing resources, we evaluate our method on two RE datasets, while disregarding scenarios such as temporal knowledge graph completion [\(Garcia-Duran et al.,](#page-8-7) [2018\)](#page-8-7), few- shot knowledge graph completion [\(Xiong et al.,](#page-10-19) [2018\)](#page-10-19) and commonsense knowledge graph comple- tion [\(Li et al.,](#page-9-18) [2022\)](#page-9-18). In future research, we plan to investigate the effectiveness of our method in border scenarios.

A Large Language Model Performance on KGC **⁸⁸⁴**

We follow [Zhu et al.](#page-11-1) [\(2023\)](#page-11-1) to assess the performance of directly instructing LLMs to perform KGC and **885** Table [7](#page-12-2) gives an example of our input to LLMs. For PaLM, we utilize the API parameter "candidate_count", **886** while for ChatGPT, we use "n" to obtain multiple candidates, enabling the calculation of Hit@1, Hit@3, 887 [a](#page-9-19)nd Hit@10 metrics. After obtaining the model's outputs, we use the Sentence-BERT [\(Reimers and](#page-9-19) **888** [Gurevych,](#page-9-19) [2019\)](#page-9-19) to guarantee each output result matches a corresponding entity in the dataset's entity set. 889

Table [8](#page-12-3) displays the additional experimental results for ChatGPT and PaLM2 across several KGC **890** datasets. It is evident that the performance of ICL of LLM falls short of KG-S2S's in every dataset. One **891** potential explanation for this subpar performance can be attributed to the phenomenon of hallucination **892** in LLMs [\(Ji et al.,](#page-9-20) [2023;](#page-9-20) [Yang et al.,](#page-10-20) [2023\)](#page-10-20), leading to incorrect responses when the LLM encounters **893** unfamiliar content. **894**

We also conducted an analysis of the influence of the number of demonstration samples. As Table [9](#page-13-2) 895 shows, we find while the number of demonstrations increases, the performance of LLMs shows a **896** corresponding improvement. It appears that augmenting the number of demonstrations in the prompt **897** could be a potential strategy for enhancing the capabilities of LLMs in KGC. Nonetheless, it's essential **898** to note that incorporating an excessive number of relevant samples as demonstrations faces practical **899** challenges, primarily due to constraints related to input length and efficiency considerations. **900**

Table 7: The prompt we use to directly leverage LLMs to perform KGC. Tail Prompt and Head Prompt mean the input to predict the missing tail and head entity respectively.

Table 8: ChatGPT and PaLM2's results on other KGC datasets.

B Details of Various KGC Pipelines **901**

B.1 Discriminative KGC Pipelines 902

KG-BERT [\(Yao et al.,](#page-10-1) [2019\)](#page-10-1) is the first to propose utilizing PLMs for triplet modeling. It employs a special **903** "[CLS]" token as the first token in input sequences. The head entity, relation, and tail entity are represented **904** as separate sentences, with segments separated by [SEP] tokens. The input token representations are **905**

	FB15k-237N				
		$H@1$ $H@3$ $H@8$			
PaLM2-1-shot	15.7	20.8	25.4		
PaLM2-2-shot	169	22.1	26.8		
PaLM2-4-shot 17.7		23.1	27.9		

Table 9: Experiment results of the demonstration number's effect on LLMs when performing KGC.

 constructed by combining token, segment, and position embeddings. Tokens in the head and tail entity sentences share the same segment embedding, while the relation sentence has a different one. The input is fed into a BERT model, and the final hidden vector of the "[CLS]" token is used to compute triple scores. The scoring function for a triple (h, r, t) is calculated as $s = f(h, r, t) = sigmoid(CWT)$, where s is a 2-dimensional real vector and CW T is the embedding of the "[CLS]" token. Cross-entropy loss is computed using the triple labels and scores for positive and negative triple sets.

 CSProm-KG [\(Chen et al.,](#page-8-2) [2023a\)](#page-8-2) combines PLM and traditional KGC models together to utilize both textual and structural information. It first concatenates the entity description and relation description behind a sequence of conditional soft prompts as the input. The input is then fed into a PLM, denoted as P, where the model parameters are held constant. Subsequently, CSProm-KG extracts embeddings from the soft prompts, which serve as the representations for entities and relations. These representations are 917 then supplied as input to another graph-based KGC model, labeled as G, to perform the final predictions. It also introduces a local adversarial regularization (LAR) method to enable the PLM P to distinguish tCSProm-KGextually similar entities. Finally, CSProm-KG utilizes the standard cross entropy loss with label smoothing and LAR to optimize the whole pipeline.

B.2 Generative KGC Pipelines

 In GenKGC [\(Xie et al.,](#page-10-0) [2022\)](#page-10-0), entities and relations are represented as sequences of tokens, rather than unique embeddings, to connect with pre-trained language models. For missing tail entities in triples $(e_i, r_i, ?)$, descriptions of e_i and r_j are concatenated to form the input sequence, which is then used to generate the output sequence. BART is employed for model training and inference, and a relation- guided demonstration approach is proposed for encoder training. This method leverages the fact that knowledge graphs often exhibit long-tailed distributions and constructs demonstration examples guided 928 by the relation r_i . The final input sequence format is defined as: $x =$ demonstration(r_i) < $SEP > d_{e_i}, dr_j < SEP$, where d_{e_i} and dr_j are description of the head entity and relation respectively. And demonstration(r_i) means the demonstration examples with the relation r_i . Given the input, the target of GenKGC in the decoding stage is to correctly generate the missing entity. Additionally, an entity-aware hierarchical decoding strategy has been proposed to improve the time efficiency.

 Following them, KG-S2S [\(Chen et al.,](#page-8-1) [2022a\)](#page-8-1) adds the entity description in the decoder end, training the model to generate both the missing entity and its corresponding description. It also maintains a soft prompt embedding for each relation to facilitate the model to distinguish the relations with similar surface meanings. Additionally, it adopts a sequence-to-sequence dropout strategy by randomly masking some content in the entity description to avoid model overfitting in the training stage.

C Additional Implementation Details

 We show the detailed statistics of the KGC datasets we use in Table [10.](#page-13-3) Table [11](#page-14-2) displays the hyper-parameters we adopt for each baseline model and dataset.

model	dataset	batch size	learning rate	epoch	α
KG-BERT	WN18RR	32	$5e-5$	5	0.1
	FB15k-237N	32	$5e-5$	5	0.1
CSProm-KG	WN18RR	128	$5e-4$	500	1.0
	FB15k-237N	128	$5e-4$	500	1.0
GenKGC	WN18RR	64	$1e-4$	10	1.0
	FB15k-237N	64	$1e-4$	10	1.0
$KG-S2S$	WN18RR	64	$1e-3$	100	0.5
	FB15k-237N	32	$1e-3$	50	0.5

Table 11: Details of hyper-parameter settings for each baseline and dataset.

D Implementation Details of Reconstruction for Generative KGC Models **⁹⁴¹**

[I](#page-9-16)n the case of GenKGC, we adhere to the denoising pre-training methodology used in BART [\(Lewis](#page-9-16) **942** [et al.,](#page-9-16) [2020\)](#page-9-16). This approach commences by implementing a range of text corruption techniques, such as **943** token masking, sentence permutation, document rotation, token deletion, and text infilling, to shuffle the **944** integrity of the initial text. The primary objective of BART's reconstruction task is to restore the original **945** corpus from the corrupted text. **946**

For KG-S2S, we follow the pre-training approach proposed by T5 [\(Raffel et al.,](#page-9-5) [2020\)](#page-9-5). This approach **947** employs a BERT-style training objective and extends the concept of single token masking to encompass **948** the replacement of text spans. In this process, we apply a 15% corruption ratio for each segment, randomly **949** substituting a span of text with a designated special token " \ll extra id>". Here we employ a span length of **950** 3. The ultimate goal of T5's reconstruction task is to accurately predict the content associated with these **951** special tokens. **952**
