Incorporating Graph Information in Transformer-based AMR Parsing

Anonymous ACL submission

Abstract

 Abstract Meaning Representation (AMR) is a Semantic Parsing formalism that aims at pro- viding a semantic graph abstraction represent- ing a given text. Current approaches employ Transformer-based Autoregressive language models such as BART or T5, fine-tuned through Teacher Forcing to obtain a linearized version of the AMR graph from a sentence. In this paper, we explore a modification to the Trans- former architecture, using structural adapters to explicitly incorporate graph structural in- formation into the learned representations and improve AMR parsing performance. Our ex- periments show how, by employing word-to- node alignment, we can construct a graph to 016 embed structural information using the hidden states through the Encoder. While employing the graph structure constitutes a data leak, we demonstrate how this information leads to a performance gain that can be preserved implic- itly via self-knowledge distillation, providing a new State-of-the-Art (SotA) AMR parser, im- proving over previous ones even without the use of additional data. We release the code at [availableafterreview](available after review).

⁰²⁶ 1 Introduction

 Creating a machine-interpretable representation of meaning lies at the core of Natural Language Un- derstanding, which has been framed as Semantic Parsing. Even though multiple formalisms have [b](#page-9-0)een proposed throughout the years (e.g., Hajič [et al.](#page-9-0) [\(2012\)](#page-9-0); [Abend and Rappoport](#page-8-0) [\(2013\)](#page-8-0); [White](#page-10-0) [et al.](#page-10-0) [\(2016\)](#page-10-0)), Abstract Meaning Representation [\(Banarescu et al.,](#page-8-1) [2013,](#page-8-1) AMR) has received more attention thanks to the large corpus available and a well-defined structure. AMR captures text seman- tics in the form of a directed acyclic graph (DAG), with nodes representing concepts and edges repre- senting semantic relationships between them. As of now, AMR is widely employed in a plethora of NLP domains, such as Information Extraction

 $1)$ Here, it is a country with the freedom of speech.

 $2)$ It is a country with the freedom of speech here.

 $3)$ Here it is a country with speech freedom.

[\(Rao et al.,](#page-10-1) [2017\)](#page-10-1), Text Summarization [\(Hardy and](#page-9-1) **042** [Vlachos,](#page-9-1) [2018;](#page-9-1) [Liao et al.,](#page-9-2) [2018\)](#page-9-2), Question An- **043** swering [\(Lim et al.,](#page-9-3) [2020;](#page-9-3) [Bonial et al.,](#page-8-2) [2020b;](#page-8-2) **044** [Kapanipathi et al.,](#page-9-4) [2021\)](#page-9-4), Human-Robot Interac- **045** tion [\(Bonial et al.,](#page-8-3) [2020a\)](#page-8-3), and Machine Translation **046** [\(Song et al.,](#page-10-2) [2019\)](#page-10-2), among other areas. Figure [1](#page-0-0) **047** shows an example of an AMR graph. 048

In recent years, autoregressive models proved **049** to be the best approach for semantic parsing be- **050** cause of their outstanding performances without **051** [r](#page-10-3)elying on sophisticated ad-hoc architectures [\(Xu](#page-10-3) **052** [et al.,](#page-10-3) [2020;](#page-10-3) [Bevilacqua et al.,](#page-8-4) [2021;](#page-8-4) [Procopio et al.,](#page-10-4) **053** [2021\)](#page-10-4). Several approaches have recently emerged **054** to increase performance by including structural **055** information into the model [\(Chen et al.,](#page-8-5) [2022\)](#page-8-5), **056** [a](#page-8-6)dding extra Semantic Role Labeling tasks [\(Bai](#page-8-6) **057** [et al.,](#page-8-6) [2022\)](#page-8-6) or by using ensembling strategies [\(Lam](#page-9-5) **058** [et al.,](#page-9-5) [2021;](#page-9-5) [Lee et al.,](#page-9-6) [2022\)](#page-9-6). **059**

In this paper, following the effort of strength- **060** ening the model's learning phase by incorporat- **061** ing meaningful structural information, we investi- **062** gate the use of structural adapters [\(Ribeiro et al.,](#page-10-5) **063** [2021a\)](#page-10-5) based on Graph Neural Networks (GNN) to **064** boost performance through self-distillation. GNN **065** is a type of neural network which deals with data **066** that has structural dependencies; that is, it can be **067**

 represented as a graph. However, graph informa- tion is not available at inference time, hence the need to transfer the knowledge of a model exploit- ing the graph structure. Knowledge Distillation (KD) is the technique that transfers the knowledge [f](#page-9-7)rom a teacher model to a student model [\(Hinton](#page-9-7) [et al.,](#page-9-7) [2015\)](#page-9-7). In our approach, we leverage concept- node alignments to generate a word-based graph with a structure similar to the original AMR. Af- ter that, such a graph is employed, with structural adapters, in the Encoder of a Transformer Encoder- Decoder architecture to obtain soft targets, which are then used for self-knowledge distillation, trans- ferring the knowledge from the teacher path with the leaked graph structure to the student, which only has access to the text.

 The main contributions of this paper are: i) ex- ploring how to add structural information into the model using structural adapters and self-knowledge distillation, ii) SotA results in AMR parsing for AMR 2.0 and AMR 3.0 datasets, iii) competitive base models for AMR parsing.

⁰⁹⁰ 2 Related Work

 Throughout the years, multiple trends have ap- peared to parse AMR graphs: using statistical methods [\(Flanigan et al.,](#page-8-7) [2014,](#page-8-7) [2016a;](#page-8-8) [Wang et al.,](#page-10-6) [2015a\)](#page-10-6), neural-transition based parsers [\(Ballesteros](#page-8-9) [and Al-Onaizan,](#page-8-9) [2017;](#page-8-9) [Liu et al.,](#page-9-8) [2018;](#page-9-8) [Fernan-](#page-8-10) [dez Astudillo et al.,](#page-8-10) [2020;](#page-8-10) [Zhou et al.,](#page-10-7) [2021a\)](#page-10-7), bidi- [r](#page-10-8)ectional transformers [\(Lyu and Titov,](#page-9-9) [2018;](#page-9-9) [Zhang](#page-10-8) [et al.,](#page-10-8) [2019;](#page-10-8) [Cai and Lam,](#page-8-11) [2020\)](#page-8-11) based on BERT [\(Devlin et al.,](#page-8-12) [2019\)](#page-8-12), sequence-to-sequence trans- formers [\(Xu et al.,](#page-10-3) [2020;](#page-10-3) [Bevilacqua et al.,](#page-8-4) [2021;](#page-8-4) [Procopio et al.,](#page-10-4) [2021;](#page-10-4) [Chen et al.,](#page-8-5) [2022;](#page-8-5) [Bai et al.,](#page-8-6) [2022\)](#page-8-6), or by ensemble models [\(Lam et al.,](#page-9-5) [2021;](#page-9-5) [Lee et al.,](#page-9-6) [2022\)](#page-9-6).

 The interest in Transformer models based on BART [\(Lewis et al.,](#page-9-10) [2020\)](#page-9-10) has constantly increased over the last years since they obtained SotA per- formances without complex pipelines. In seman- tic parsing, these models face the task similarly to Neural Machine Translation, where the text is translated into a linearized version of the graphs. [T](#page-8-4)he earliest attempts [\(Xu et al.,](#page-10-3) [2020;](#page-10-3) [Bevilacqua](#page-8-4) [et al.,](#page-8-4) [2021\)](#page-8-4) were trained with pairs of sentences and graphs, so the model automatically generates the representation of the sentences.

115 Lately, some works have extended sequence-to-**116** sequence models to incorporate extra information **117** useful for parsing. [Procopio et al.](#page-10-4) [\(2021\)](#page-10-4) leverages multitask learning to improve cross-lingual AMR **118** parsing results. [Chen et al.](#page-8-5) [\(2022,](#page-8-5) ATP) expand the **119** dataset with extra auxiliary tasks such as Seman- **120** tic Role Labeling and Dependency Parsing, with **121** pseudo-AMR graphs constructed based on a par- **122** ticular task. During training, a special task tag is **123** added at the beginning of the input sentence, and **124** the ATP model predicts the output for such a task. **125** [Bai et al.](#page-8-6) [\(2022,](#page-8-6) AMRBART) pre-train the model 126 on 200k graphs generated by SPRING where gener- **127** ated linearized graphs are modified with a masking **128** strategy and used as input. Additionally, they use **129** a unified strategy involving the concatenation of a **130** masked graph and a masked text. The model needs **131** to reconstruct the original sequence, similarly to **132** Masked Language Modeling. In such a way, the **133** model improves structure awareness of Pretrained **134** Language Models (PLM) over AMR graphs. More- **135** over, recent research has shown the capabilities of **136** the autoregressive models for extracting alignment **137** [i](#page-9-11)nformation online while parsing [\(Huguet Cabot](#page-9-11) **138** [et al.,](#page-9-11) [2022\)](#page-9-11). Finally there is a recent surge of **139** ensemble models. [Lam et al.](#page-9-5) [\(2021\)](#page-9-5) devised a **140** [n](#page-9-6)ew strategy to merge predicted graphs, and [Lee](#page-9-6) **141** [et al.](#page-9-6) [\(2022\)](#page-9-6) expanded on it by ensemble distilla- **142** tion. However we decide not to compare our work **143** with ensemble strategies, as they rely on multiple 144 parsers, such as our proposed one, rendering com- **145** parisons unfit. **146**

3 Fundamentals **¹⁴⁷**

3.1 AMR Parsing with BART **148**

AMR parsing can be defined as a sequence-to- **149** sequence (seq2seq) problem where the input $x = 150$ $(x_1, ..., x_n)$ is a sequence of n words (or subwords) 151 and the output $g = (e_1, ..., e_m)$ is a linearized 152 graph with m elements. Our goal is to learn a **153** function that models the conditional probability: **154**

$$
p(g|x) = \prod_{t=1}^{m} p(e_t|e_{< t}, x), \tag{1}
$$

where $e_{\leq t}$ are the tokens of the linearized graph g 156 before step t . **157**

Suppose we have a dataset D of size |D| which 158 consists of pairs (x^i, g^i) , with each g^i having length 159 $mⁱ$. Our objective is then to minimize a negative 160

161 log-likelihood loss function:

$$
L_{nll}(D) = -\sum_{i=1}^{|D|} \log p(g^i | x^i) =
$$

$$
= -\sum_{i=1}^{|D|} \sum_{t=1}^{m^i} \log p(e_t^i | e_{\le t}^i, x^i)
$$
 (2)

Figure 2: Top: sentence. Middle: AMR graph. Bottom: Linearized graph. Alignment is represented by colours.

 In order to model the problem, one can ex- ploit the transfer learning capabilities of BART. In [Bevilacqua et al.](#page-8-4) [\(2021,](#page-8-4) SPRING), the vocabulary of BART is updated with tokens corresponding to 167 i) AMR-related tokens, ii) variable names <R0>, 168 <R1>, ... <Rn> and other tokens needed for the various graph linearizations. In addition, BART is **fine-tuned with the input x and the target q. The ap-** proach described in this work is built on top of the SPRING model, which we consider our baseline **173** system.

174 3.2 AMR alignment

 Since the AMR graph represents the semantic meaning behind a sentence, there exists an align- ment between the spans in text and semantic units in graphs. In Figure [2,](#page-2-0) we can find an example. No- tice how most of the words are connected to a node in the graph but some, such as the preposition *a*, are not reflected or aligned to the graph. Indeed, some Semantic Parsers rely on alignment to be trained [\(Wang et al.,](#page-10-9) [2015b;](#page-10-9) [Flanigan et al.,](#page-8-13) [2016b;](#page-8-13) [Misra](#page-9-12) [and Artzi,](#page-9-12) [2016;](#page-9-12) [Damonte et al.,](#page-8-14) [2017;](#page-8-14) [Zhou et al.,](#page-10-10) [2021b\)](#page-10-10). Multiple alignment formalisms have been

[p](#page-8-7)roposed through the years, such as JAMR [\(Flani-](#page-8-7) **186** [gan et al.,](#page-8-7) [2014\)](#page-8-7), ISI [\(Pourdamghani et al.,](#page-9-13) [2014\)](#page-9-13) or **187** LEAMR [\(Blodgett and Schneider,](#page-8-15) [2021\)](#page-8-15). We will **188** leverage alignment to construct a graph based on **189** the words in the sentence and their representation. **190**

3.3 Structural adapters **191**

[Ribeiro et al.](#page-10-11) [\(2021b\)](#page-10-11) have shown how the Trans- **192** former architecture can be modified to improve **193** PLM for modeling graph information. They in- **194** troduced the Structural Adapter (StructAdapt), a **195** residual neural network involving a Graph Convo- **196** lutional (GraphConv) layer. **197**

We employ structural adapters to encode the **198** graph structure imposed by a Word-Aligned Graph **199** (see Section [4.1\)](#page-3-0), leading to the construction of a **200** graph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$, where each token of the input x 201 is linked to a node $v \in V$, and $\mathcal E$ is an unlabeled set 202 of edges $\{(u, v)|u, v \in V\}$. Moreover, we remove 203 layer normalization and set GELU as an activation **204** function (Figure [4\)](#page-3-1). Then, for each hidden repre- **205** sentation $\mathbf{h}_v^l \in \mathbb{R}^b$ from the encoder layer l and 206 the set of edges \mathcal{E} , we compute the updated hidden 207 states \mathbf{z}_v^l as: **208**

$$
\mathbf{g}_v^l = \text{GraphConv}_l(\mathbf{h}_v^l, \mathcal{E})
$$

$$
\mathbf{z}_v^l = \mathbf{W}_a^l \sigma(\mathbf{g}_v^l) + \mathbf{h}_v^l,
$$
 (3)

where σ is GELU and $\mathbf{W}_a^l \in \mathbb{R}^{b \times b}$ is a parameter 210 matrix of the feed-forward layer.

Likewise [Ribeiro et al.](#page-10-11) [\(2021b\)](#page-10-11), the adapters are **212** inserted after each Encoder's layer having the same **213** amount of adapters as encoder layers (Figure [5\)](#page-4-0). **214**

Graph Convolution In a similar manner to **215** [Ribeiro et al.](#page-10-11) [\(2021b\)](#page-10-11), we use GraphConv proposed **216** by [Kipf and Welling](#page-9-14) [\(2017\)](#page-9-14) and computed as: **217**

$$
\text{GraphConv}_{l}(\mathbf{h}_{v}^{l}, \mathcal{E}) = \sum_{u \in \mathcal{N}(v)} \frac{1}{\sqrt{d_{u}d_{v}}} \mathbf{W}_{g}^{l} \mathbf{h}_{u}^{l}, \tag{4}
$$

where $\mathcal{N}(v)$ is a set that contains v and its adja- 219 cent nodes, d_v is the degree of v , $\mathbf{W}_g^l \in \mathbb{R}^{b \times b}$ is a 220 parameter. **221**

4 Model **²²²**

In the next section, we explain how we have **223** extended the SPRING architecture in order to **224** leverage AMR structure information from word- **225** nodes alignments using structural adapters and self- **226** knowledge distillation. **227**

(3) **²⁰⁹**

, (4) **218**

Figure 3: Different representations of the sentence: "Here, it is a country with the freedom of speech". An AMR with edges converted in nodes (left), a Full WAG (center) and a Contracted WAG (right).

Figure 4: Structural adapter without layer normalization and with GELU activation.

228 4.1 Word-Aligned Graph

 Using AMR alignment, we design a Word-Aligned Graph (WAG) representation where nodes and rela- tions are actual words of the input sentence instead of the AMR concepts when it is possible. First, we convert the relations into nodes that connect two adjacent nodes in the original graph (see Figure [3,](#page-3-2) left). Then, we replace the nodes and relations with the aligned words of their respective sentence (Figure [3,](#page-3-2) center).

 Unfortunately, a problem arises when dealing with the structural adapter since non-aligned nodes (e.g., the :location relation in Figure [3\)](#page-3-2) do not have associated hidden states. Therefore, in order to use WAG in the structural adapter, we have two alternatives: i) remove nodes for which we do not have hidden states, i.e., contract non-aligned nodes (see Section [4.1.1\)](#page-3-3), or ii) create new hidden states for them (see Section [4.1.2\)](#page-3-4).

247 4.1.1 Contracted WAG

 For the first approach, we must remove non-aligned nodes from the graph. However, deleting the nodes from the original graph would produce a discon-nected graph. To achieve a similar connected structure to the original graph, we contract nodes rather **252** than remove them. A contracted WAG (CWAG) **253** is a graph in which non-aligned nodes are com- **254** pressed with the closest parent node, preserving all **255** relations from both nodes. Figure [3](#page-3-2) (right) depicts **256** an AMR and its corresponding CWAG. Addition- **257** ally, in multi-token nodes (e.g., "Romneycare"), we **258** merge to the first token any of the subword tokens. **259**

4.1.2 Full WAG **260**

In the second representation, we preserve the nodes **261** without alignment (the node "location" in Figure 262 [3](#page-3-2) (center)). First, if the node's label is in the **263** new AMR special tokens which were added to the **264** model's vocabulary (e.g., :location), we extract the **265** embedding from the embedding matrix. Other- **266** wise, we tokenize the node's label and take the **267** average of their embedding tokens as the represen- **268** tation. Furthermore, the representations for the non- **269** aligned nodes are added to the model in the first **270** adapter layer by concatenating them with the hid- **271** den states of the encoder. After each adapter block, **272** we split representations into two groups: i) the up- **273** dated hidden states for the original input tokens, **274** which are inputs for the next Transformer layer, 275 ii) the updated hidden states for the non-aligned **276** nodes, which are concatenated again before the **277** next adapter block. This type of graph is referred **278** to as a Full WAG (FWAG). Figure [3](#page-3-2) (center) shows **279** an example of FWAG. **280**

4.2 Graph Leakage Model (GLM) **281**

Through WAG, we explore whether information **282** leakage has an impact on performance. In this man- **283** ner, we can determine the model's upper bound per- **284** formance with the enhanced Encoder, determining **285** which graphs and adapter architectures are suitable 286 for the Two-Path Model described in Section [4.4.](#page-5-0) **287**

Thereby, we insert structural adapters in each **288**

Figure 5: Left: Scheme of Graph Leakage Model. Right: Scheme of Two-Path Model, where parameters of the original BART Encoder and Decoder are shared partially among two paths: (green) path incorporating WAG information via adapters, (red) path omitting adapters which is basically the outcome model for the problem.

 Transformer layer of the Encoder (Figure [5](#page-4-0) left). The adapter's input in a layer l consists of a matrix 291 of hidden states H^l and the set of edges \mathcal{E} . In the 292 case of CWAG, H^l corresponds to hidden states of Transformer layer l. Whilst, for FWAG, we add extra representations as described in Section [4.1.2.](#page-3-4) Note that the set of edges $\mathcal E$ does not change through layers. The loss function for GLM is:

$$
L_{leak} = L_{nll}(\tilde{D}),\tag{5}
$$

298 where \tilde{D} is the updated dataset consisting of pairs 299 $((x^i, a^i), g^i)$, where a^i is the WAG.

300 GLM performance may be considered as the **301** upper model's bound in which the encoder learns **302** graph information from alignments.

303 4.3 Knowledge Distillation

 GLM leverages the alignment information to en- hance the model's conception of the graph struc- ture to improve the parsing performance of the model. Unfortunately, WAG cannot be employed at inference time since alignment information is not available when parsing text to predict a graph. Therefore, following the idea of knowledge dis- tillation, we set the teacher to be the pre-trained GLM that employs the structural information using sentences and WAGs as input, and then we project such knowledge to the student model, which is just

aware of the sentences, with no adapters. There- **315** fore, our objective is to achieve the following: **316**

$$
f_{stud}(x) = f_{GLM}(x, a), \tag{6}
$$

where a is the WAG. 318

For this purpose, we set SPRING as the student. **319** The fundamental objective is to encourage the stu- **320** dent to match the teacher's probability distribution **321** by minimizing the following loss: **322**

$$
L_{KL}(p,q) = KL(p,q) = \sum_{i=0}^{C-1} p_i \log(\frac{p_i}{q_i}), \quad (7)
$$

where q and p are probabilities of the teacher and 324 the student respectively, KL is Kullback–Leibler **325** divergence, C is the number of classes. Usually, **326** the loss L_{nll} for the original task is added to the 327 total loss: **328**

$$
L_{KD} = L_{nll} + \alpha L_{KL},\tag{8}
$$

), (7) **323**

where α is a hyper-parameter. 330

The architectural differences between the teacher **331** and the student model belong to the encoder, not **332** the decoder, since the teacher is the one with the **333** structural adapters. Therefore, we copy the GLM **334** decoder to the student model and fix the decoder **335** and the language model head parameters. **336**

5

337 4.4 Two-Path Model

 We propose a Two-Path Model (TPM) for learning where, in contrast with the KD approach, a single model is trained via two paths simultaneously, one path with the structural adapters and the other with- out them. Then, we force the two paths to learn the same distribution by adding a Kullback–Leibler divergence loss on the output logits. As a result, the total loss is:

$$
L_{TPM} = \alpha L_{KL} + \beta L_{leak} + L_{nll}, \qquad (9)
$$

 where L_{leak} is the loss for the first path, with leaked information, L_{nll} is the loss for the second path, which is the original negative log-likelihood loss, and finally L_{KL} is the above-described Kull- back–Leibler divergence loss. α, β are hyper-parameters to control each loss scale.

 Notably, the Two-Path Model is a variant of knowledge distillation as described in Section [4.3,](#page-4-1) called self-knowledge distillation [\(Hahn and Choi,](#page-9-15) [2019\)](#page-9-15). In this case, we project the knowledge via the adapter's path rather than computing soft tar- get probabilities. Moreover, we calculate KL di- vergence for all classes to distill more knowledge from the first path. Finally, based on the assump- tion that there is not enough information to distill at the initiation of the training process, we train 363 with scheduling the L_{leak} multiplier β , where β is gradually decreasing.

³⁶⁵ 5 Experimental Setup

 To demonstrate the benefits of incorporating struc- tural information in AMR parsing, we devise a set of experiments to assess its performance with re- spect to State-of-the-Art models. Before delving into their details, we first provide thorough infor- mation regarding the dataset (Subsection [5.1\)](#page-5-1) and model (Subsection [5.2\)](#page-5-2) used in our experiments.

373 5.1 Datasets

 We tested on two AMR benchmark datasets: i) AMR 2.0, which has 36521, 1368, and 1371 sentence-AMR pairs in the training, validation, and test sets, respectively, and ii) AMR 3.0, which con- tains 55635, 1722, and 1898 sentence-AMR pairs in the training, validation, and test sets, respectively. Furthermore, we tested on the Little Prince and the Bio AMR out-of-distribution datasets.

382 Alignment Our approach directly relies on the **383** structural information extracted between the wordconcept alignment. There are several alignment **384** standards: First, Information Sciences Institute **385** (ISI) provides extended AMR 2.0 and AMR 3.0 **386** datasets with alignments of all the graph seman- **387** tic units that are directly related to the sentences' **388** spans [\(Pourdamghani et al.,](#page-9-13) [2014\)](#page-9-13). Second, Lin- **389** guistically Enriched AMR [\(Blodgett and Schneider,](#page-8-15) **390** [2021,](#page-8-15) LEAMR) achieves full graph-alignment cov- **391** erage by aligning all the graph semantic units to **392** anything in the sentence. **393**

Silver Data Following [Bevilacqua et al.](#page-8-4) [\(2021\)](#page-8-4), **394** we have explored the same strategy to generate **395** a dataset with 140k silver sentence-graph pairs. **396** The silver alignments were generated using the **397** approach of [Huguet Cabot et al.](#page-9-11) [\(2022\)](#page-9-11), where they **398** are extracted from the cross-attention of the model. **399**

5.2 Models **400**

We use SPRING [\(Bevilacqua et al.,](#page-8-4) [2021\)](#page-8-4) as our 401 baseline model, an auto-regressive model based on **402** BART [\(Lewis et al.,](#page-9-10) [2020\)](#page-9-10) for predicting linearized **403** versions of AMR graphs. Our models have been **404** built on top of SPRING, inheriting some of its **405** hyper-parameters (see Table [7\)](#page-11-0). Structural adapters **406** leverage one graph convolutional layer and GELU **407** activation. In the next paragraphs, we explain the **408** specific setup per each model. **409**

Graph Leakage Model We explore two differ- **410** ent settings for GLM: i) *Contracted WAG*, Section **411** [4.1.1](#page-3-3) - Figure [3](#page-3-2) right; and ii) *Full WAG*, Section **412** [4.1.2](#page-3-4) - Figure [3](#page-3-2) center. **413**

Knowledge Distillation We test KD on the GLM **414** with the highest SMATCH (see Table [1\)](#page-6-0). 415

Two-Path Model Likewise GLM, we first exam- **416** ine the difference in performance between Con- **417** tracted WAG and Full WAG. Then, we test Full **418** WAG with i) β scheduling, ii) the silver data, iii) 419 the combination of the silver data and the β schedul- 420 ing. In the case of the scheduling of β , we start **421** from $\beta = 90$ and decrease it linearly at each iter- 422 ation for 21k iterations in total until it reaches 10. **423** The hyper-parameter α is set to 20. 424

6 Results **⁴²⁵**

Graph Leakage Model Table [1](#page-6-0) shows results for **426** the Graph Leakage Model. While this setup relies **427** on information being leaked from the final graph **428** structure, it sets an upper bound on how encoding **429** such information can improve performance. Here **430**

Model	AMR 3.0
SPRING	84.10
Contracted WAG	86.01
Full WAG	89.58
Leaked Path of TPM	86.09

Table 1: GLM results for AMR 3.0 development set.

	Model	AMR 3.0
	SPRING	84.10
КĐ	Full WAG (89.58)	83.90
Two-Path	$L_{leak} + L_{nll}$ $L_{leak} + L_{nll} + L_{KL}$	84.47 85.04

Table 2: Knowledge Distillation results for the development set of AMR 3.0.

Model	AMR 3.0
SPRING	84.10
Contracted WAG	84.90
Full WAG	85.04
$+ \beta$ scheduling	85.08
+ Silver	85.34
+ Silver + β scheduling	85.28

Table 3: Performance of Two-Path models on the development set of AMR 3.0.

 we observe an increase of around five SMATCH points when including concept labels and token masking. While the model is certainly taking ad- vantage of the leaked information, this is encoded through the hidden states of the Encoder. There- fore we need to explore whether some of this per- formance gain can be kept implicitly without any information leak.

 Knowledge Distillation and TPM Table [2](#page-6-1) com- pares the results between applying KD with GLM as the teacher versus the self-KD approach, TPM, explained in Section [4.4.](#page-5-0) We see how KD alone falls short of taking full advantage of the perfor- mance gains of GLM. On the other hand, TPM, especially when including the KL loss, leads to over one SMATCH point increase on the develop- ment set. Hence we focus on TPM as our main approach. Table [3](#page-6-2) shows a breakdown of the exper- iments with TPM, such as scheduling the KL loss or adding a silver data pretraining phase.

Model	TLP	BioAMR
SPRING	81.3	61.6
ATP	79.0	55.2
AMRBART	82.3	63.4
Ours	82.6	64.5

Table 4: Out of distribution results. ATP, AMRBART and SPRING are taken from [Lee et al.](#page-9-6) [\(2022\)](#page-9-6)

Model	AMR 2.0	AMR 3.0
SPRING	82.8	
AMRBART	83.6	82.5
Ours	84.7	83.5

Table 5: BART-base versions performance.

Main Results Table [6](#page-7-0) shows results for our pro- **451** posed model, based on BART-large. Our system **452** performs better than any previous single model **453** parser, and most notably, does so even without the **454** need of extra data. For AMR 2.0, we see up to **455** 0.7 SMATCH increase over AMRBART and 0.4 **456** on AMR 3.0. The use of extra data only leads to **457** a small improvement, showing the efficiency of **458** our approach which is able to outperform previous **459** SotA systems that relied on up to 200K extra sam- **460** ples. In the breakdown performance, we see how **461** our system performs worse than ATP on Reentran- **462** cies, Negation and notably SRL. We believe this is **463** due to the multitask nature of ATP, where SRL is **464** explicitly included as a task. This opens the door **465** to future work exploring the interaction between **466** our approach and the inclusion of auxiliary tasks. **467**

BART base Our SotA system relies on BART- **468** large, which has 400M parameters. While it shows **469** great performance, it has a big computational foot- **470** print, especially at inference time due to its auto- **471** regressive generative nature. This makes the need **472** for lighter, more compute efficient models an im- **473** portant step towards better Semantic Parsers. Table **474** [5](#page-6-3) shows the performance of our approach when **475** trained on top of BART-base, which has 140M **476** parameters, achieving 83.5 SMATCH points on **477** AMR 3.0, 1 point higher than AMRBART and, **478** noticeably, surpassing SPRING-large performance **479** by half a point. We believe it is crucial to have **480** close to SotA performance base models, closing **481** the gap from 2 points to 1 when compared to its **482** large counterparts. **483**

Table 6: Results and comparisons with previous systems. Bold indicates best performance per set, underline in case of a tie. Breakdown extra scores after vertical line. Upperscript indicates result is significantly better using an approximate randomization test [\(Riezler and Maxwell,](#page-10-12) [2005\)](#page-10-12) at $p < 0.05$. $s = SPRING, a = ATP$. Ours is the only system significantly better than ATP.

Figure 6: SMATCH score for buckets of 200 instances. X axis shows max. number of words per sentence.

 Out-of-distribution evaluation Table [4](#page-6-4) shows the Out-of-Distribution of TPM. We see a smaller improvement on TLP, 0.3 over AMRBART. On the harder BioAMR, performance increased over a point, showing how the model is able to generalize well on different domains.

⁴⁹⁰ 7 Performance Analysis

 Seq2seq parsers show decreased performance for longer sentences since a single error at decoding time in an early step can lead to compound errors and suffer from exposure bias. We explore how this affects our model compared to SPRING, ATP and AMRBART. Figure [6](#page-7-1) shows the SMATCH per- formance on AMR 3.0 test set for buckets of 200 sentences divided by the number of words. While

the performance is similar on shorter sentences, **499** with AMRBART showing slightly better performance, with longer sentences of over 14 words 501 TPM shows better performance, especially com- **502** pared to the baseline, which drops to 80 SMATCH **503** points for longer sentences. This experiment also **504** shows how performance is relatively stable for 505 medium length sentences (10-30 words, oscillat- **506** ing around 85 points), while it starts deteriorating **507** for longer ones. The high performance on short **508** sentence is likely due to expressing easy-to-parse **509** structures such as single date sentences. **510**

8 Conclusion 511

We presented a new approach to training the Trans- **512** former architecture where partial information of the **513** target sequence can be learned via multi-tasking **514** and self-knowledge distillation: the information **515** can be leaked in the Encoder implicitly through **516** Transformer adapters which improve training but **517** are switched off during inference. By employing **518** this approach in AMR parsing, we achieved SotA **519** results among non-ensemble methods. Moreover, **520** we produced a lightweight AMR parser that outper- **521** forms SPRING having four times fewer parameters. **522** We also showed that, for all methods, including **523** ours, performance degrades as the number of words **524** increases, which raises a question of limitation of **525** the current methods based on BART. **526**

Interestingly, our approach can be potentially **527** used in other tasks where alignments between input **528** and target sequence elements exist, or structural **529** information is unavailable at inference time. **530**

⁸⁴⁸ Appendices

849 **A** Model Hyper-Parameters

850 Table [7](#page-11-0) lists hyperparameters and search space for **851** the experiments:

- **852** LR sched. learning rate scheduler
- **853** KL temp. KL temperature
- **854** AMR 3 aligns. a type of alignments for **855** AMR 3.0
- **856** Mask. range masking range. For each batch, **857** we mask the input tokens with probability p, **858** the value for which is sampled uniformly from **859** the masking range.

Table 7: Final hyperparameters and search space for the experiments

860 **B** Hardware and size of the model

 We performed experiments on a single NVIDIA 862 3090 GPU with 64GB of RAM and Intel® CoreTM i9-10900KF CPU. The total number of trainable parameters of TPM is 434,883,596. Training the model on the silver data took 33 hours, whereas 865 further fine-tuning took 16 hours.

C BLINK **⁸⁶⁷**

All systems from Table [6](#page-7-0) use BLINK [\(Ledell Wu,](#page-9-16) **868** [2020\)](#page-9-16) for wikification. For this purpose, we used **869** the blinkify.py script from the SPRING reposi- **870** tory. **871**

D Metric **⁸⁷²**

We evaluate AMR parsing using the Smatch met- **873** [r](#page-8-14)ic [Cai and Knight](#page-8-16) [\(2013\)](#page-8-16) and extra scores of [Da-](#page-8-14) **874** [monte et al.](#page-8-14) [\(2017\)](#page-8-14): i) Unlabel, compute on the **875** predicted graphs after removing all edge labels, **876** ii) No WSD, compute while ignoring Propbank **877** senses (e.g., duck-01 vs duck-02), iii) Wikification, 878 F-score on the wikification (:wiki roles), iv) NER, **879** F-score on the named entity recognition (:name **880** roles), v) Negations, F-score on the negation detec- **881** tion (:polarity roles), vi) Concepts, F-score on the **882** concept identification task, vii) Reentrancy, com- **883** puted on reentrant edges only, viii) Semantic Role **884** Labeling (SRL), computed on :ARG-i roles only. **885**

E Data 886

The AMR 3.0 data used in this paper is licensed **887** under the *LDC User Agreement for Non-Members* **888** for LDC subscribers, which can be found [here.](https://catalog.ldc.upenn.edu/LDC2020T02) The **889** *The Little Prince* Corpus can be found [here](https://amr.isi.edu/download.html) from **890** the Information Science Institute of the University **891** of Southern California. **892**

F Limitations **⁸⁹³**

At train time, our system requires alignment be- **894** tween graph and sentence. We obtain them for **895** the silver data with an external system which over- **896** comes this limitation, but other systems do not rely **897** on alignment. Since we have two pathways in- **898** side the TPM architecture, the model requires two 899 forward paths. Along with the fact that we have **900** three losses, the model is considered computation- **901** ally heavier than its competitors from Table [6](#page-7-0) at **902** training time. However, the number of parameters **903** and computational cost/time remains the same at **904** inference time. **905**
