NBDESCRIB: A Dataset for Text Description Generation from Tables and Code in Jupyter Notebooks with Guidelines

Anonymous ACL submission

Abstract

Generating cell-level descriptions for Jupyter Notebooks, which is a major resource consisting of codes, tables, and descriptions, has been attracting increasing research attention. However, existing methods for Jupyter Notebooks mostly focus on generating descriptions from code snippets or table outputs independently. On the other side, descriptions should be personalized as users have different purposes in different scenarios while previous work ignored 011 this situation during description generation. In 013 this work, we formulate a new task, personalized description generation with code, tables, and user-written guidelines in Jupyter Notebooks. To evaluate this new task, we collect and propose a benchmark, namely NBDESCRIB, containing code, tables, and user-written guide-018 lines as inputs and personalized descriptions as targets. Extensive experiments show that while existing models of text generation are able to generate fluent and readable descriptions, they still struggle to produce factually correct descriptions without user-written guidelines. CodeT5 achieved the highest scores in Orientation (1.27) and Correctness (-0.43) among foundation models in human evaluation, while the ground truth scored higher in Orientation (1.45) and Correctness (1.19). Common error patterns involve misalignment with guidelines, incorrect variable values, omission of important code information, and reasoning errors. Moreover, ablation studies show that adding guidelines significantly enhances performance. both qualitatively and quantitatively.

1 Introduction

040

042

043

In recent years, computational notebooks like Jupyter have become popular among data scientists and machine learning researchers for documenting ideas, writing code, and visualizing results in a single document (Wang et al., 2021a). Description in a notebook provides a rich medium for users to record what the code does and the reasoning behind it. Description is found essential for data scientists to share or reuse code (Zhang et al., 2020; Chattopadhyay et al., 2020). However, research has shown that many data scientists still neglect to write appropriate descriptions for their code in notebooks, especially for code output (*i.e.* table), as they feel writing description will slow down their coding process (Ramasamy et al., 2023). Rule et al. (2018a) reported that among one million computational notebooks on Github, 25% of them have no comment. Besides, unlike other integrated development environments (IDEs) such as Visual Studio, data scientists working in computational notebooks often write concise descriptions, typically less than 100 words(Wang et al., 2022). This brevity poses challenges for large language models (LLMs), such as GPT and LLaMA, limiting their ability to generate accurate markdown descriptions(Park and Choi, 2024).

Existing literature has explored techniques to generate descriptions for code snippets or table outputs independently (Richardson et al., 2017; Li et al., 2021; Liu et al., 2018; Parikh et al., 2020a; An et al., 2022; Zhao et al., 2023b,a; Ding and Xu, 2023; Cm et al., 2023), achieving satisfying performance. However, in real-world applications, documentations are always related to the corresponding code and table output, at the same time. For example, ground truth descriptions require summarization from the code and table output simultaneously, as shown in Section 1.

Moreover, while the same code-table output pair could serve different purposes under different user requirements, existing work (Zhao et al., 2023b; Chen et al., 2020; Zhao et al., 2023a; Ding and Xu, 2023; Cm et al., 2023; Richardson et al., 2017; An et al., 2022; Liu et al., 2021; Khan and Uddin, 2022; Koehn and Knowles, 2017; Pasupat and Liang, 2015; Ye et al., 2023) only focuses on description generation for either code or table without considering various user requirements. As shown in Figure 044

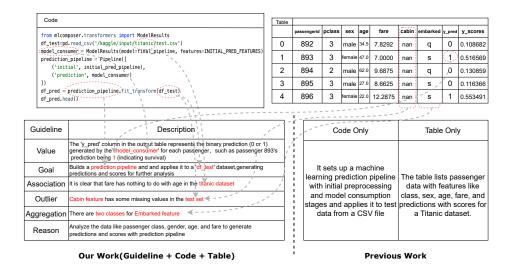

Figure 1: An example in our proposed NBDESCRIB dataset, which targets generating **high-fidelity and personalized descriptions** based on the input of codes, tables, and user-written guidelines. Previous methods and benchmarks focus on understanding the codes or tables only, which makes the generated description unfaithful.

1, under different user-written guidelines, the focus of different ground-truth descriptions could differ from each other.

To address the aforementioned issues and step forward in faithful and personalized description generation, in this paper, we propose a challenging user-written guideline-based text generation task focusing on the table and code description generation (**TCDG**) for Jupyter Notebooks. Given codes and output tables, the goal of **TCDG** is to produce a concise description under different user-written guidelines. The guidelines will be of a given category corresponding to the type of target text as shown in Table 2.

Moreover, we construct the first benchmark (NBDESCRIB) for TCDG that contains 3,924 processed code-table-description pairs extracted from highly-ranked notebooks from Kaggle competitions and identifies 15 guideline categories of the texts (details in Section3). Specifically, the raw Jupyter Notebook data with tables, code, and associated text from popular Kaggle competitions is crawled. However, the raw data cannot be directly used due to the large amount of noise (Mondal et al., 2023; Lin et al., 2022). For example, "I plan to refine the models by using more sophisticated machine learning techniques." is about personal experiences and future plans, which is not useful for text generation tasks. On the other side, the userwritten guidelines and ground-truth descriptions in the markdown cell generally contain multiple different purposes or facts on the tables. To reduce the noise in the raw data, we recruit annotators to first break down the markdown cells and make each piece of text only contain one purpose or fact. For each guideline category, we create the label as well

as descriptions, and then curate the tables and filter out the noise text. Finally, the text descriptions in our data are natural, faithful, and specifically targeted under different guidelines (Figure 1). 121

Next, we evaluate the performance of existing pretrained models. The ablation study shows that guidelines significantly affect the final performance at different levels, which demonstrates the validity of our task. Human evaluation further shows that these advanced models (*i.e.*, CodeT5, Llama, and GPT-40) still struggle to produce faithful enough results, regardless of high-quality training data. Moreover, common error patterns involve misalignment with guidelines, incorrect variable values, omission of important code information, and reasoning errors.

Based on these results, we integrated our approach into a user-facing application to explore Human-AI collaboration in code documentation. In a follow-up study, users found that the generated documentation reminded them of documenting codes they might have overlooked and increased their satisfaction with their notebooks.

The main contributions of our work are:

- We formulate a novel task, **TCDG**, and collect a high-quality benchmark, namely NBDESCRIB;
- Experiments show that fine-tuned LMs (CodeT5) outperform powerful pretrianed models, *i.e.*, GPT-40 and Llama, highlighting the vulnerability of LLMs on TCDG. Ablation studies and downstream application demonstrate that guide-lines significantly enhance model performance, helping users create accurately oriented and reasonable descriptions.
- Error analysis shows that LLMs fail to align with guidelines, understand variable values, and rea-

2 **Related Work**

son.

In this work, we focus on table and code description generation (TCDG) tasks. Our work is closely related to table-to-text generation and code documentation generation (CDG). Most existing datasets for table-to-text generation (Li et al., 2021; Liu et al., 2018; Parikh et al., 2020a; Dhingra et al., 2019; Zhao et al., 2023b; Chen et al., 2020; Zhao et al., 2023a; Ding and Xu, 2023; Cm et al., 2023; Zhang et al., 2024; Guo et al., 2024; Min et al., 2024) or code documentation (Richardson et al., 2017; An et al., 2022; Liu et al., 2021; Khan and Uddin, 2022; Dvivedi et al., 2024; Luo et al., 2024) generation contain one text per table or code on a specific topic and schema. For instance, (Suadaa et al., 2021) contains 1.3K table-documentation pairs with richer inference from scientific papers and CodeSearch-Net (Husain et al., 2019) contains 2M functiondocumentation pairs across six programming languages (e.g., java, php, python). Differing from previous CDG and table-to-text datasets, a documentation text can correspond to both code and its table output in ours.

Previous work on table-to-text focuses on text generation for standalone table data. Parikh et al. (2020b) proposed an open domain table-to-text dataset. They collected tables from Wikidepia and paired them with single-sentence documentation. They then requested annotators to revise the Wikipedia candidate sentences into target sentences, rather than writing new ones. Several studies focused on a specific topic and schema such as WEATHERGOV (Liang et al., 2009) and ROBOCUP (Chen and Mooney, 2008), Rotowire (Wiseman et al., 2017), Wikibio (Lebret et al., 2016, Biographies), E2E (Novikova et al., 2016, Restaurants). However, they cannot provide different target texts for various data facts in tables, resulting in too singular results during model training.

Another task similar to table-to-text is table question answering (Pasupat and Liang, 2015; Wang et al., 2018; Nan et al., 2022; Cheng et al., 2021; Ye et al., 2023). While they can locate relevant tables and provide answers by tagging relevant cells, they do not provide a meaningful explanation of different kinds of data facts. There are also other sources of information that may be used in data science projects. Without following appropriate guidelines and integrating these sources, we would not be able

to produce satisfactory results. Chen et al. (2019); Gupta et al. (2020) attempted to verify whether a provided textual statement is entailed or refuted by the given table. But they only address verification issues and cannot generate descriptive statements for different data fact types.

Since our work focuses on both code and table, it is essential to discuss related work on CDG, which aims to understand the code and generate the code descriptions. Typical datasets include CodeSearchNet (Husain et al., 2019) and some datasets collected from GitHub (Kanade et al., 2019) or BigQuery (Yue Wang, 2021). Recently, LLMs have been applied to the CDG task such as CodeLlama (Roziere et al., 2023), CuBERT (Kanade et al., 2019), CodeBERT (Feng et al., 2020), GraphCodeBERT (Guo et al., 2020)) or GPT (Svyatkovskiy et al., 2020; Lu et al., 2021). Some recent works explore encoder-decoder models such as PLBART (Ahmad et al., 2021), CodeT5 (Yue Wang, 2021), and TreeBERT (Jiang et al., 2021). The documentation in this task often does not cover the facts of the output from the code, only focusing on the description of the code.

Different from the aforementioned works that only focus on one text generation for a single standalone code or table, in our new TCDG task for computational notebooks, code and its table output can correspond to one description, and these descriptions may have many categories depending on the needs of the user. We thus propose to construct a notebookTCDG dataset to handle text generation of multiple guideline categories for code and its table output.

3 **TCDG - Task Description**

In our task, the model is provided with a long text including a code cell and its table output, as well as the corresponding guideline category description. The guideline indicates the direction of the target description generation, and the specific category is described in Section 4.3. The model is asked to read the input and generate reasonable descriptions based on the given guideline, code, and table.

3.1 Input

The input to a text generation model consists of an input text and a target document:

(1) Codes and tables from the input texts are extracted from notebooks crawled from the Kaggle website. The code provides the necessary context to understand how the table output was generated.

Table 1: NBDESCRIB dataset statistics.

By analyzing the code, one can infer the logic and algorithms applied to the input data, which facilitates accurate interpretation of the table's contents.

(2) A guideline category description serves as a guiding principle for generating the target description. Some descriptions focus on interpreting table content while code snippets also provide essential contextual information. At the same time, while describing the purpose of the code, we also need tables to provide essential data-driven explanations. This setup mimics the real scenario.

A text generation model is employed to predict the specific guideline category of descriptions. Table code associated Markdown cells are the target documents that we collect since these cells are typically used to provide descriptive text for code and tables. Also, some Markdown cells can be used only for headings in the notebook. To exclude such Markdown cells, search for key characters like #, which generally refers to the titles.

4 NBDESCRIB

4.1 Data Collection

As we are focusing on the description generation in Jupyter Notebooks, we need to crawl a sufficient number of code-table-description pairs first. Publicly shared notebooks on GitHub are often illdocumented (Rule et al., 2018b) and do not have many tables, thus are not suitable for this task.

On the other side, Kaggle allows community members to vote up and down on uploaded notebooks, and findings show that the highly-voted notebooks are of good quality and quantity for code documentation (Wang et al., 2021b; Liu et al., 2021). Thus, we decided to utilize the topvoted and well-documented Kaggle notebooks. We crawled notebooks from seven popular competitions, *i.e.*, seven top popular Kaggle competitions - House Price Prediction, Titanic Survival Prediction, Predict Future Sales, Spaceship Titanic, U.S. Patent Phrase to Phrase Matching, JPX Tokyo Stock Exchange Prediction, and Ubiquant Market Prediction, and built around 4,000 pairs of code-tabledescription pairs. Links for these competitions can be found in Appendix C. To build this dataset, we also filtered out the description which is not in English. We checked the data policy of each of the competitions, and none of them have copyright issues. We also contacted Kaggle to make sure our data collection complies with the platform's policy.

4.2 Data Preprocessing

We employed the following heuristics to collect codes, tables, and Markdown:

Cell Matching: We search for codes that produce tables in the notebooks and check if there is a corresponding Markdown cell describing the code and table above. The sentences are also split if there are multiple sentences in the corresponding Markdown cell. However, there are instances where the text content is inaccurate. For example, in texts labelled as value guidelines, the extracted value might be incorrect, or in texts describing Feature Engineer guidelines, the variable name extracted from the code might be misspelled. Thus, we label each sentence and let annotators rewrite it accordingly, since each sentence may have a different description angle. Details about how annotators code the sentence and reach an agreement are shown in Section 4.3. The specific guideline details will be described in the following.

Table Processing: Since the table in Jupyter Notebook is in HTML code, to transfer it into a table format, we use HTMLParser¹ to get the data value for each row, column, and their relationship based on the tags, such as , . We first drop their parent tags to simplify the document format. Next, we remove the tags and from cells to extract variables and corresponding values from the HTML code. Then we concatenate variables and values with pipe("|") to generate table description. An example of table processing is shown in Appendix I.

Table Curation: If the description contains variable names in a table, the corresponding rows and columns containing those variables are extracted to create a new table. If no key variables are included, we keep the original tables. This process

Three members of the research team conducted an iterative open-coding process to analyze the collected notebooks. Differing from Wang et al. (2020), where their qualitative coding stopped at the tabular data level, and our analysis goes deep to the granularity of the cell, the cell be used to explain beyond the adjacent code cell whose output is the table: we annotate these cells' purposes and types of content. Each annotator independently analyzed the same five notebooks to develop a codebook. After discussing and refining the codebook, they again went back to recode those five notebooks and achieved pairwise inter-rater reliability ranged 0.81-0.93 (Cohen's K). To further determine the correctness of inter-annotator agreement, we let these three annotators analyze another undiscussed five notebooks and get pairwise inter-rater reliability ranging from 0.78 to 0.89 (Cohen's K) which is convincing to demonstrate the reliability of our codebooks. After getting a reliable agreement, the three coders divided and coded the remaining notebooks. In total, we identified fifteen guideline categories for the content of the markdown cells (Table 2, Appendix E provides examples).

> As shown in Table 2, eleven guideline categories mainly focus on the data facts of a table. It is worth noting while these guidelines focus more on the description of the table data, the code still provides contextual information to supplement their description, as shown in Figure 1. Our analysis revealed that markdown cells are mostly used to describe the specific attribute values from the table (Value, 7.29%). Second to the Value category, 6.55% markdown cells are used to specify the outliers from the table output (Outliers).

However, these guidelines do not meet the needs of Jupyter Notebook users. This kind of markdown cells can also be used to mainly explain the beyond adjacent code cells. Even though they mainly focus on the code, a clear understanding of table data is also crucial for understanding the code logic.

We found that some of these markdown cells describe the motivation from the code descriptive text(Goal, 19.64%), to explain the results or critical decisions (Reason, 7.03%), or to describe a combination of mathematical transformations from the code (Feature Engineer, 10.02%). We also found

Guideline	#	Description			
Value 286 (7.29%)		Get the exact data attribute values for a set of criteria.			
Difference 138 (4o2%)		A comparison between at least two distinct attributes within the target object, or a comparison between the target object and previously measured values.			
Trend	31 (0.79%)	Indicates a general tendency over a period of time.			
Proportion	120 (3.06%)	Measure the proportion of selected data attribute(s) within a specified set			
Categorization	74 (1.89%)	Select the data attribute(s) that meet the condition.			
Distribution 127 (3.20%) Rank 73 (1.86%) Association 165 (4.21%)		Show the amount of shared value for the selected data attributes or present a breakdown of all data attributes.			
		Sort data attributes by their values and display a breakdown of selected attributes.			
		Identify the useful relationship between two or more data at- tributes.			
Extreme	227 (5.78%)	Identify the data cases that are the most extreme in relation to the data attributes or within a specific range			
Outlier	257 (6.55%)	Determine whether there are unexpected data attributes or statis- tically significant outliers.			
Aggregation	125 (3.19%)	Calculate the descriptive statistical indicators (e.g., average, sum, count, etc.) based on the data attributes.			
Goal	771 (19.64%)	Express user's goal. To say what value or function they tend to use for the later research			
Reason	276 (7.03%)	Express reason using the data from the table or explain the rea- sons why certain functions are used or why a task is performed.			
Feature Engi- neer	393 (10.02%)	The process of selecting, transforming, extracting, combining, and manipulating raw data to generate the desired variables for analysis or predictive modeling.			
Complementary Details	870 (22.17%)	Express additional contextual elements and supporting informa- tion to enhance understanding of the primary content			

Table 2: We identify 15 guideline categories based on the types of descriptions in the Markdown cells which are below the code whose output is a table.

that some markdown cells aim to provide additional context to help with code and table understanding (Complementary Details, 22.17%).

4.4 Train / Dev / Test Splits

Overall, the dataset contains 2747 Code-Table-Description pairs in the training set, 393 pairs in the development set, and 785 pairs in the test set (see Table 1 for more statistics).

5 Experiments

Baselines. We utilized three types of models: a fine-tuned encoder-decoder-based CodeT5, the popular decoder-only LLMs (an off-the-shelf GPT-40, Llama3, CodeLlama3), and a fine-tuned GPT-3.0. Details are shown in Appendix D.

5.1 Evaluation Metrics

We use the ROUGE scores (ROUGE-1, ROUGE-2, and ROUGE-L) (Lin, 2004), BERTScore (Zhang et al., 2019), and G-EVAL (Liu et al., 2023a) to evaluate our model's performance with regard to the ground-truth description content. Details are shown in Appendix H.

5.2 Results

The numbers in Table 3 show that this guidelinebased text generation task is very challenging,

Models	ROUGE-1	ROUGE-2	ROUGE-L	BERTScore	Pyramid Evaluation	G-EVAL:Coherence	G-EVAL:Correctness	G-EVAL:Consistency	G-EVAL:Fluency
	Ba	selines							
CodeT5	29.61	14.38	26.72	59.51	19.37	3.12	2.43	2.78	3.98

Table 3: ROUGE scores and BERTScore for the baselines, our model, and the ablation studies. Results show that this task is challenging though we use it in the state-of-art text generation models.

while the fine-tuned CodeT5 obtained the best per-419 formance. It is interesting to note that CodeLlama3 420 has bad performance in this task. The possible rea-421 son is that CodeLlama3 focuses mainly on code 422 generation and is not suitable for description gen-423 eration. As shown in Table 3, CodeT5-Large out-424 performs the GPT-40, GPT-3, Llama3, and CodeL-425 lama3 in this task. Additionally, we notice that the 426 ROUGE-L of CodeT5-Large is above 25, and the 427 ROUGE-2 is around 15, indicating that our dataset 428 can produce more accurate and fluent text in re-429 sponse to different guidelines in this task. However, 430 431 these metrics primarily check for semantic similarity. To further evaluate generated descriptions in 432 diverse dimensions and achieve higher human cor-433 respondence, we conduct LLM-based evaluators 434 G-EVAL (Liu et al., 2023b) in four dimensions (Co-435 herence, Correctness, Consistency, and Fluency) 436 on a 5-point Likert Scale. Details of G-EVAL are 437 shown in Appendix H. we can find that CodeT5-438 Large outperforms the GPT-40, GPT-3, Llama3, 439 and CodeLlama3 in this task. It is interesting to 440 note that existing LLM can generate fluent descrip-441 tions but struggle to produce coherent and consis-442 tent descriptions. 443

> Ablation Study: To better understand the impact of each component on this new task, we perform ablation studies(Table 3) to evaluate how table, code, and guideline description contribute to the model performance separately. More concretely, we generate ablation models with the following settings: (1) without table, (2) without code, (3) without guideline description, (4) chain of thought prompting on GPT-40, (5) in-context learning on GPT-40.

444

Note that table content has a bigger effect on model performance compared to code. Code also influences performance by providing the necessary context to infer the logic, which aids in interpreting the table's content accurately. Guideline description can be seen as a synergy of tables that guide the generation system to generate desirable topics, and without it, the performance is slightly higher than one without any table content.

One intuitive method to enhance the reasoning ability of LLMs is Chain-of-Thoughts (CoT). Here we want to further answer this question: using CoT, can a large language model automatically find an optimum guideline and generate summaries better aligned with human interests? CoT is well known to work well for GPT models, so we experimented on GPT-40 with a CoT prompt containing both an example and middle steps of guessing a guideline (prompts shown in Appendix F). For a fair comparison, we also added the performance of incontext-learning for GPT-40, by removing the provided guideline and directly providing the example (prompts shown in Appendix G). The result of CoT improved over in-context learning but is still inferior to the performance of the original GPT-40 with ground-truth guidelines (except ROUGE-2).

Then we analyzed the match rate between guidelines generated through the CoT process and the ground truth. Results show that 72% of the guidelines did not match. Thus, although LLM can often generate readable and decent descriptions for code and table(see results in Table 5 and Table 3), most of the generated descriptions are not as the users expected (see result in Orientation dimension in Table 5). This demonstrates the necessity of guidelines. To fairly compare the generation models and standardize evaluation, we need to specify ourguidelines for generating descriptions.

Pyramid Evaluation: We employ an automatic 497 evaluation method based on pyramid evaluation 498 (PyrEval) (Gao et al., 2019) to assess the faithful-499 ness of generation. This metric, which correlates 500 well with human evaluation, extracts and filters key 501 phrases to preserve factual information, offering a more reliable metric to ROUGE. The results in Table 3 show consistent trends between PyrEval 504 and ROUGE, validating the impact of table, code, 505 and guideline descriptions in our ablation studies. 506

5.3 Human Evaluation

507

508

510

511

512

513

515

516

We conducted a human evaluation with 10 participants to assess the performance of various LLM models in generating code documentation. Participants rated 50 pairs of code and documentation across three dimensions: Correctness, Orientation, and Readability. The results showed that the Ground Truth outperformed other baselines. Results and analysis are deferred to Appendix A.

6 Error Analysis

In this section, we analyze some common error 517 cases in this guideline-based text generation task. 518 Some examples can be found in the Appendix B. 519 (1) Variable values were generated and matched incorrectly. As shown in the example in Table 4, even 521 522 though CodeT5-Large, GPT-40, GPT-3, Llama3, and CodeLlama3 are capable of generating key-523 words such as "highest" based on the "Extreme" guideline, it remains difficult to produce accurate 525 text content based on the variables in the table. For 526 example, CodeT5-Large incorrectly predicted the oldest passenger as 80 years old. Table 4 also has 528 this kind of error. 529

(2) The generated text focuses solely on the table
and ignores important information in the code. In
the example from Table 10, ground truth is in
the "Extreme" guideline and tends to convey that
the first red wine has the highest pH value. However, the table does not have a related keyword "red
wine." And CodeT5 failed to extract this information and also extracted the wrong value. GPT-40
cannot generate correct description either. Example
from Table 8 also has this kind of error.

(3) Generating incorrectly oriented text based on guidelines. For example, GPT-3, Llama3, and CodeLlama3 produce text related to "Difference",
"Extreme", or "Distribution", but not "Trend" in the example from Table 7. Another example in

Guideline category description

Extreme: Identify the data cases that are the most extreme in relation to the data attributes or within a specific range

Code Cells

cols2 = X_test.columns.tolist() # List of column names
X_test = X_test[cols2] # Applying the new order
X_test

Table									
Passenger	Sex	Age	Embarked	FamilySize					
0	0	34.5	1	1					
1	1	47.0	2	2					
2	0	62.0	1	1					
3	0	27.0		1					
4	1	22.0	2	3					
Description	l								
ground tr	uth	The	The oldest passenger in X_test dataset						
		is 62	2 years old						
CodeT5-L	arge	Olde	Oldest person in the titanic was 80						
		year	s old and you	ungest person was less					
		than	than one year						
GPT-40			It shows the initial rows of the table						
01110			providing insights into the age distribu-						
		1	0 0	s, with the label draw-					
CDT 2		e		he oldest passenger					
GP1-3	GPT-3 Llama3		The oldest passenger is a man in his fifties						
Llama3			÷ .	sengers ranging from					
				old with the youngest					
		pass	enger being	27 years old					
CodeLlan	na	The	The average age of the passengers is						
		34.5	years old.						
			-						

Table 4: An example of code-table cells and different models. Note that the table above is the original table, which will be processed by the table curation in Section 4.2 when generating the description. In this case, the curated table only keeps the passenger and age columns.

Table 8, requires models generating text related to "Goal", but GPT-3 generates text related to "Association", describing the relationship between SibSP and Parch. Llama3 also generates text in "Feature Engineer" but not "Aggregation" in the example from Table 6.

(4) Reasoning error. If operating under Aggregation guidelines, CodeT5, GPT-40, and GPT-3 may generate incorrect Aggregation data (count, mean, sum). In this example (Table 6), GPT-3 can generate text such as this feature has many null values, but cannot obtain the count of null values.

We manually check 50 examples of CodeT5, GPT-40, GPT-3, Llama3, and CodeLlama3 models used in our user study and label the type of errors made. The most errors are made when they generate incorrectly oriented text (3rd type) (54.1%).

Figure 2: We implement a downstream application as a Jupyter Notebook plugin (A) to assist users in documentation writing for selected rows and columns from different guideline categories (B) and a user-prompt approach (C).

This is because the model tends to generate documents related to the best-trained guideline type in the dataset, such as "Association" or "Value". There are also two common errors made by generating documents with wrong values (1st type) and wrong reason (4th type) (**27**% respectively). Such errors are commonly made by generating "Value" or "Aggregation" type documents. There are also **13.5%** errors made by generating documents without considering the code. The dataset has numerous examples with insufficient code, leading the model to overlook some code instances.

These errors show that our task and dataset provide some challenges for existing foundation models. We firmly believe that researchers can enhance the existing foundation models in the future when they address the challenges. By building on our work and leveraging the valuable insights gained from it, they can push the boundaries even further, contributing to the continuous evolution of foundation models.

7 Downstream User Application

To demonstrate the application of our benchmark NBDESCRIB, we designed a Jupyter Notebook plugin to assist document writing in data science programming (as shown in Figure 2).

The plugin is triggered when detecting users focusing on a code cell (Figure 2.A). The plugin then reads the contents from the focused cell and its curated table output based on the selected columns and rows and sends the content to the backend. The backend server first generates documentation under different guideline categories using fine-tuned CodeT5-Large(Figure 2.B). In addition, we used prompts to nudge users to explain an output (Figure 2.C). If the user selects one of his preferred candidates, the chosen documentation will be inserted below the code cell.

Our plugin went through several rounds of pilot testing and iterative design. Participants found that it reminded them to document code they would have ignored, reducing the time spent developing documentation while actively exploring the data science task. Full implementation details and a formal evaluation of the human-AI collaboration for automatic documentation will be reported separately after the paper is accepted.

8 Conclusion

In this paper, we formulated a new task, TCDG, that aimed to automatically generate descriptive text for code and table based on the given guidelines for a computational notebook. We collected a large amount of well-documented Jupyter Notebooks from Kaggle, resulting in a new benchmark dataset **NBDESCRIB**. From our analysis, our task imposed unique challenges to the current generation methods, including CodeT5 and LLMs. This dataset facilitated the creation of practical slides for Jupyter notebooks and enabled evaluations on faithful, high-fidelity, and factual generation.

670

671

As annotations are often performed by multiple individuals, there may be a degree of subjectivity and bias in guidelines and datasets used for text generation. As a result, text can be generated that does not reflect a diverse range of perspectives. Furthermore, although we have automatic evaluation metrics such as ROUGE and BERTScore, the correctness of the generated texts is primarily evaluated through human evaluation, which is accurate but not efficient. Future research should focus on developing methods for automatically evaluating the factual correctness of the generated texts, in order to ensure that the generated text is accurate, unbiased, and representative of a diverse range of perspectives.

> One potential risk involves the substantial computational resources needed to run state-of-the-art language models. These resources consume significant amounts of energy, which not only raises the carbon footprint of such research but also leads to environmental degradation.

A Appendix: Human Evaluation

We also conduct a human evaluation to further evaluate whether those models can generate reasonable and oriented text with our dataset.

Participants: Our human evaluation task involves reading the code snippet, its output table, and a guideline description and rating the generated documentation from them. We recruited 10 participants (6 male, 4 female) who are fluent English speakers with around six years of experience in the data science and machine learning field. We conducted a rigorous qualification process, evaluating their knowledge of coding practices and data analysis, to ensure high-quality annotations. We hired them by sending invited emails to graduate students who have experience in data science work. We allocated up to 90 minutes for each participant to complete the study, and for their valuable time and input, each participant received a compensation of \$20.

Task: We randomly selected 50 pairs of documentation and code from NBDESCRIB. Note that each pair has only one code, one table, and one guideline description, but may have one descriptive text. Each participant is assigned 50 pairs. Each pair is evaluated by 10 individuals. In each trial, a participant reads 8 candidate descriptions for the same code snippet-table-guideline: one by GPT-40 with chain-of-thought, one by GPT-40 with in-contextlearning, one as the ground truth, and another five by five different models. The order of these eight is also randomized, so participants do not know which descriptive text is from which model. The participant is asked to rate the 8 documentation texts along three dimensions using a five-point Likert scale from -2 to 2.

- *Correctness*: The generated description matches the code and table content.
- *Orientation*: The generated description is written in the correct guideline category.
- *Readability*: The generated description is in readable English grammar and words.

Evaluation Results: We conducted *Wilcoxon tests* (Woolson, 2007) with a significance level of 0.05 to compare the performance of Ground Truth against CodeT5-Large, GPT-3, and GPT-40 in the Correctness, Orientation, and Readability dimensions. The Wilcoxon test is a non-parametric statistical test used to compare two paired groups of data. The obtained p-values indicate the probability of observing the reported differences if there were no true differences between the models. The results indicate significant differences in the Correct-1039 ness dimension, where Ground Truth outperforms 1040 CodeT5-Large (V = 5628, p = 1.74e-30), GPT-3 1041 (V = 5635, p = 5.46e-31), GPT-40 (V = 5639, p = 1042 2.84e-30), Llama3 (V = 5732, p = 3.32e-30), and 1043 CodeLlama (V = 5948, p = 1.27e-30). It is also 1044 worth noting that CodeT5 performs slightly better 1045 than GPT-40 in terms of correctness from Table 5, 1046 possibly because it handles code-containing data 1047 sets better. 1048

Similarly, in the Orientation dimension, Ground Truth surpasses CodeT5-Large (V = 3567, p = 1.59e-20), GPT-3 (V = 3731, p = 1.77e-20), GPT-40 (V = 3675, p = 1.64e-20), Llama3 (V = 3722, p = 1.89e-20), and CodeLlama (V = 3883, p = 1.33e-20).

For the Readability dimension which considers whether the generated description is a valid English sentence, Ground Truth outperforms all models once again: CodeT5-Large (V = 4363, p = 1.40e-7), GPT-3 (V = 4030, p = 3.81e-14), GPT-40 (V = 4135, p = 2.81e-10), Llama3 (V = 4556, p = 2.38e-13), and CodeLlama (V = 4573, p = 1.62-15). It is also worth noting that GPT-40 with chain-ofthought and in-context-learning have worse performance than GPT-40 which demonstrates that guidelines can better assist the description generation for code and table.

The statistically significant p-values (all below 0.05) in each dimension demonstrate it is difficult to meet the correctness, orientation, and readability requirements of the user due to the difficulty of the task. Future work can be accomplished by designing an innovative model to address this challenge.

1072

Model	Correctness	Orientation	Readability
Groundtruth	$\overline{x} = 1.19, \sigma = 1.32$	$\overline{x} = 1.45, \sigma = 1.02$	$\overline{x} = 1.61, \sigma = 0.78$
CodeT5-Large	$\overline{x} = -0.43, \sigma = 1.55$	$\overline{x} = 1.27, \sigma = 1.11$	$\overline{x} = 0.55, \sigma = 1.60$
GPT-40	$\overline{x} = -0.42, \sigma = 1.49$	$\overline{x} = 1.15, \sigma = 1.24$	$\overline{x} = 0.53, \sigma = 1.72$
GPT-3	$\overline{x} = -0.41, \sigma = 1.58$	$\overline{x} = 0.98, \sigma = 1.39$	$\overline{x} = 0.51, \sigma = 1.61$
Llama3	$\overline{x} = -0.44, \sigma = 1.41$	$\overline{x} = 1.03, \sigma = 1.42$	$\overline{x} = 0.51, \sigma = 1.82$
CodeLlama	$\overline{x} = -0.61, \sigma = 1.39$	$\overline{x} = 0.88, \sigma = 1.36$	$\overline{x} = 0.52, \sigma = 1.69$
GPT-40 with chain-of-thought	$\overline{x} = -0.39, \sigma = 1.54$	$\overline{x} = 0.94, \sigma = 1.35$	$\overline{x} = 0.48, \sigma = 1.66$
GPT-40 with in-context-learning	\overline{x} = -0.35, σ =1.60	$\overline{x} = 0.91, \sigma = 1.28$	$\overline{x} = 0.46, \sigma = 1.83$

Table 5: Human Evaluation Result.

D Appendix: Detail of Baseline Models

CodeT5 is a large pre-trained encoder-decoder Transformer model that better leverages the code semantics conveyed from the developer-assigned identifiers. Since CodeT5 is a competitive coderelated text generation model, when using this model in our task, we converted the relevant table and guideline category description into an inline comment in code and then fine-tuned the model. It has 770 million parameters and the computational budget is around 3 hours.

GPT-3 (Generative Pre-training Transformer 3) is an autoregressive language model with 175 billion parameters, 10x more than any previous nonsparse language model. To use the GPT3 model for our task, we combine guideline description, code, and table as input text. It has 175 billion parameters. The computational budget is around 1 hour. To use the GPT-3 model, we register an account on OpenAI and use the related API (openai api fine_tunes.create⁹) to fine-tune the GPT-3 model. Also, we built a dataset suitable for GPT-3 training, which can shared with the public.

GPT-40 is an advanced iteration of the GPT-3 model with around 12 billion parameters and a default backend of free ChatGPT. The computational budget is around 1 hour and 15 minutes. Its ability to comprehend context, generate coherent and contextually relevant responses, and perform a wide array of language-related tasks is further refined. It is an easily accessible tool and has been widely used in real life. So we add it as an advanced baseline.

1140

Llama3 (Touvron et al., 2023). We use Llama3 3.1-70B in this task. It is an advanced language model with approximately 70 billion parameters. Its default backend is designed for efficiency and scalability. The computational budget for Llama3 is approximately 1 hour and 30 minutes. Its ability to understand context, generate coherent and contextually relevant responses, and perform a wide range of language-related tasks is significantly enhanced. Llama3 is a powerful and accessible tool, widely used in various applications. Therefore, it is included as an advanced baseline.

CodeLlama3 (Roziere et al., 2023) is an advanced version of the Llama3 model. We use the 13B version in this task. The model aims to handle complex code generation and comprehension tasks efficiently. The computational budget of CodeLlama3 is about 2 hours. CodeLlama3 performs well in understanding intricate programming contexts, generating accurate and contextually appropriate code, and performing various code-related tasks. Its accessibility and versatility have made it a valuable tool for developers and researchers, serving as an advanced baseline for code-centric applications.

Guideline	Ν	Description	Example
Value	286 (7.29%)	Get the exact data attribute values for a set of criteria	The mean survived rate is 38.3 denoting most of the passengers did not survive
Difference	138 (3.52%)	A comparison between at least two dis- tinct attributes within the target object, or a comparison between the target ob- ject and previously measured values.	The difference though narrows down considerably if we were to consider group of 2 woman travelers
Trend	31 (0.79%)	Indicates a general tendency over a period of time.	table is displayed in a descending trend in accuracy
Proportion	120 (3.06%)	Measure the proportion of selected data attribute(s) within a specified set	8 of 10 passengers have parents
Categorization	74 (1.89%)	Select the data attribute(s) that meet the condition.	1 denotes survived while 0 denote not survived
Distribution	127 (3.20%)	Show the amount of shared value for the selected data attributes or present a breakdown of all data attributes.	Fare value range from 7 to 13
Rank	73 (1.86%)	Sort data attributes by their values and display a breakdown of selected attributes.	Selecting the top 3 classifiers for model prediction
Association	165 (4.21%)	Identify the useful relationship between two or more data attributes.	These two passengers are in the same PClass
Extreme	227 (5.78%)	Identify the data cases that are the most extreme in relation to the data attributes or within a specific range	Model 1 has the highest accuracy
Outlier	257 (6.55%)	Determine whether there are unexpected data attributes or statistically significant outliers.	Age column has some missing values
Aggregation	125 (3.19%)	Calculate the descriptive statistical indi- cators (e.g., average, sum, count, etc.) based on the data attributes.	There are 2 classes in the Deck
Goal	771 (19.64%)	Express user's goal. To say what value or function they tend to use for the later research	We use the Gaussian Process Classifier to plot the confusion matrix
Reason	276 (7.03%)	Express reason using the data from the table or explains the reasons why certain functions are used or why a task is performed.	We go through deleting the column for Cabin deleting 2 rows for Emabarked and since Age plays some role we can
Feature Engi- neer	393 (10.02%)	The process of selecting, transforming, extracting, combining, and manipulat- ing raw data to generate the desired vari- ables for analysis or predictive model- ing.	Delete Name and Ticket due to it s high cardinality
Complementary Details	870 (22.17%)	Express additional contextual elements and supporting informa- tion to enhance understanding of the primary content	Column details, counts, and data types provide supplementary technical informat about the Titanic passenger dataset struc

Table 11: We identify 15 guideline categories based on the types of descriptions in the Markdown cells which are below the code whose output is a table.

H Appendix: G-Eval in Coherence, Consistency, Correctness, and Fluency

H.1 Definition

G-EVAL is a prompt-based evaluation system with three main components: 1) a prompt defining the evaluation task and criteria, 2) a chain-of-thoughts (CoT) that includes intermediate instructions generated by the LLM to outline the detailed evaluation

steps, and 3) a scoring function that uses the LLM to calculate scores based on the probabilities of the returned tokens. The prompt should also contain customized evaluation criteria for different NLG tasks. 1262

1279

1280

Coherence The overall quality of all sentences working together. This aligns with the DUC (Dang, 2005) quality question on structure and coherence, which states that "the summary should be wellstructured and well-organized, building from sentence to sentence to form a coherent body of information about a topic." Followed by (Liu et al., 2023a), we conduct the G-EVAL in the four dimensions below:

Consistency The generated description is written in the correct guideline category. A factually consistent summary contains only statements that are supported by the source document. Annotators were instructed to penalize summaries containing hallucinated facts.

1330

Fluency The quality of individual sentences. According to the DUC (Dang, 2005) quality guidelines, sentences in the summary "should have no formatting problems, capitalization errors, or obvious grammatical errors (e.g., fragments, missing components) that make the text difficult to read."

Correctness Determine whether the actual output is factually correct based on the expected output.

H.2 Prompt Details for obtaining metrics

You will be given one description written for a code, its table output, and its guideline category description. Your task is to rate the description on one metric. Please make sure you read and understand these instructions carefully. Please keep this document open while reviewing, and refer to it as needed.

Evaluation Criteria:

Coherence (1-5) - the collective quality of all sentences. We align this dimension with the DUC quality question of structure and coherence whereby the description should be well-structured and well-organized. The descripition should not just be a heap of related information, but should build from sentence to sentence to a coherent body of information about a topic.

Evaluation Steps:

 Evaluation Steps:
 Read the code, its table output, and its guideline category description carefully and identify the main topic and key points.
 Read the description and compare it to the source text including the code, its table output, and its guideline category description. Check if the description covers the main topic and key points of the source text, and if it presents them in a clear and logical order.
 Assign a score for coherence on a scale of 1 to 5, where 1 is the lowest and 5 is the highest

1331 based on the Evaluation Criteria.

Example:
Source Text:
{{Guideline Category Description} {Code}
{Table}}
Description:
{{Description}}
Evaluation Form (scores ONLY):

You will be given one description written for a code, its table output, and its guideline category description. Your task is to rate the description on one metric. Please make sure you read and understand these instructions carefully. Please keep this document open while reviewing, and refer to it as needed.

Evaluation Criteria:

Correctness (1-5) - Determine whether the actual output is factually correct based on the expected output.

Evaluation Steps:

1. Read the code, its table output, and its guideline category description carefully and identify the main topic and key points. 2. Read the description and compare it to the source text including the code, its table output, and its guideline category description. Check if the description covers the main topic and key points of the source text, and if it presents them in a clear and logical order. 3. Assign a score for correctness on a scale of 1 to 5, where 1 is the lowest and 5 is the highest based on the Evaluation Criteria. Example: Source Text: {{Guideline Category Description} {Code} {Table}} Description: {{Description}}

Evaluation Form (scores ONLY):

I.3 Table Curation from the the table in H.2

In the above example, the ground truth description is: "From the count column, we find that some variables have missing values"". Based on the Table Curation method in Section 4.2, we extract the "count"" keyword from the ground truth description and extract this related column to generate the final table.

count
PassengerId 418.0
