The Music Maestro or The Musically Challenged, A Massive Music Evaluation Benchmark for Large Language Models

Anonymous ACL submission

Abstract

Benchmark plays a pivotal role in assessing the advancements of large language models (LLMs). While numerous benchmarks have been proposed to evaluate LLMs' capabilities, there is a notable absence of a dedicated benchmark for assessing their musical abilities. To address this gap, we present ZIQI-Eval, a comprehensive and large-scale music benchmark specifically designed to evaluate the music-related capabilities of LLMs. ZIQI-Eval encompasses a wide range of questions, covering 10 major categories and 56 subcategories, resulting in over 14,000 meticulously curated data entries. By leveraging ZIQI-Eval, we conduct a comprehensive evaluation over 15 LLMs to evaluate and analyze LLMs' performance in the domain of music. Results indicate that only GPT-4 is capable of effectively understanding and generating music, achieving an average accuracy rate, suggesting that there is ample room for improvement in existing LLMs. With ZIQI-Eval, we aim to provide a standardized and robust evaluation framework that facilitates a comprehensive assessment of LLMs' music-related abilities.

1 Introduction

In recent years, large language models (LLMs) have made significant advancements, revolutionizing various natural language processing tasks. These models have showcased their proficiency in tasks such as accessing and reasoning about world knowledge.

Benchmark evaluation has played a crucial role in assessing and quantifying the performance of LLMs across different domains. Traditional benchmarks tailored to particular tasks such as coding (Austin et al., 2021), reading comprehension (Li et al., 2022), and mathematical reasoning (Cobbe et al., 2021), in light of the advancements made by LLMs, are increasingly regarded as inadequate for assessing their comprehensive capabilities. Consequently, there has been a surge in the emergence of more comprehensive benchmarks (Liang et al., 2022; Srivastava et al., 2022).

However, both the traditional and comprehensive benchmarks have failed to adequately address the musical accuracy of large language models. Music is an essential part of human life and culture, and assessing LLMs' understanding and generation of music presents a unique and challenging task. This oversight emphasizes the necessity for a comprehensive evaluation framework specifically designed to capture the nuances of the musical domain.

Therefore, we present ZIQI-Eval, an extensive and comprehensive music benchmark specifically crafted to assess the music-related abilities of LLMs. ZIQI-Eval comprises a diverse range of questions, systematically organized into 10 major categories and 56 subcategories. These categories cover various aspects of music, including music theory, composition, genres, instruments, and historical context. In addition, this music benchmark actively contributes to the recognition of female music composers. By incorporating valuable content from these composers, it rectifies the gender disparity prevalent in historical literature, fostering advancement and inclusivity within the realm of music scholarship. With over 14,000 carefully crafted data entries, ZIQI-Eval provides a rich and extensive resource for evaluating LLMs' comprehension and generation of music-related content.

Utilizing ZIQI-Eval, we carry out a comprehensive experiment over 17 LLMs, comprising API-based models and open-source models, to evaluate the performance of LLMs in the realm of music. Specifically, we fed music knowledge or the first half of a musical score, along with four options, into LLMs to assess their ability to select the correct option and provide meaningful explanations. With an average accuracy rate of just 51.9%, even the top-performing model, GPT-4, falls short in demonstrating comprehensive music understand-

ing and generation capabilities. This observation not only exposes the overlooked aspect of music in LLMs but also emphasizes the significance of ZIQI-Eval in bridging this gap and tackling the inherent challenges associated with it.

In summary, our main contributions are as follows:

- We find that existing evaluations of the capabilities of large models have overlooked their musical abilities. Therefore, we propose ZIQI-Eval benchmark, a manually curated, large-scale, and comprehensive benchmark for evaluating music-related capabilities. It consists of 10 major categories and 56 subcategories, encompassing over 14,000 data entries.

- We conduct evaluations on the music comprehension and music generation capabilities of 17 LLMs and find that almost all of them struggled to understand music effectively, let alone generate it.

- We explore the issue of bias in LLMs' music capabilities, focusing on gender bias, racial bias, and region bias. Our research reveals that....

2 Related Work

Music Comprehension Inspired by the field of natural language processing (NLP), previous studies represented music as embedding sequences for music understanding. Chuan et al. (2020) and Liang et al. (2020) partition music pieces into distinct, non-overlapping segments of fixed duration, and train embeddings for each segment.

Later, with the development of large language models (LLMs), recent research has utilized the modeling capabilities of these models to further enhance the understanding of music. MidiBERT (Chou et al., 2021) and MusicBERT (Zeng et al., 2021) both utilize pre-trained BERT to tackle symbolic-domain discriminative music understanding tasks. MusicBERT further designs OctupleMIDI encoding and bar-level masking strategy to enhance pre-training with symbolic music data. Gardner et al. (2023) extracts music-related information from an open-source music dataset and uses instruction-tuning to instruct their proposed model LLark to do music understanding, music captioning, and music reasoning. NG-Midiformer (Tian et al., 2023) first processes music pieces into sequences, followed by leveraging N-gram encoder to understand symbolic music.

Music Generation Before the proliferation of LLMs, there are some other traditional methods proposed for music generation, mainly falling into three categories: neural networks, neural audio codecs, and diffusion models.

Engel et al. (2019), Marafioti et al. (2020), Greshler et al. (2021), Yu et al. (2021), Caillon and Esling (2021) employ neural network architectures such as CNNs, RNNs, or GANs to achieve music generation. A neural audio codec typically contains an encoder and a decoder. Valenti et al. (2020) follows the typical structure. Petermann et al. (2021) additionally employs skip connections between the corresponding pair of encoder-decoder layers to promote reconstruction performance. Grachten et al. (2020) encodes the input as a distribution rather than a single value for each dimension. Some models such as Jukebox (Dhariwal et al., 2020), AudioLM (Borsos et al., 2023), and MusicLM (Agostinelli et al., 2023) further insert a vector quantizer between the encoder and the decoder to learn a discrete latent representation. A diffusion model iteratively adds Gaussian noise and then learns to reverse the diffusion process to construct desired data samples from the noise. Kong et al. (2020) proposed DiffWave, a non-autoregressive model that converts the white noise signal into structured waveform through a Markov chain. Chen et al. (2020) combines score matching and diffusion models to generate high fidelity audio samples. Yang et al. (2023), Huang et al. (2023a), and Liu et al. (2023) utilize latent diffusion approach to generate high-quality music.

Since the advent of LLMs, researchers gradually began to explore the application of LLMs in music domain. AudioGen (Kreuk et al., 2022) and MusicGen (Copet et al., 2023) both use an autoregressive transformer-based decoder (Vaswani et al., 2017) that operates on the discrete audio tokens. Macaw-LLM (Lyu et al., 2023) incorporates visual, audio, and textual information by using an alignment module to unite multi-modal features to textual features for LLM to generate response. M^2UGen (Hussain et al., 2023) exploits the potential of LLM to bridge multi-modal music comprehension and generation. It utilizes LLaMA2 model to comprehend the multi-modal contextual information of the input and perform downstream tasks such as

music question-answering and music generation guidance.

Benchmark Evaluations Benchmark evaluation plays a crucial role in assessing the development of LLMs. Previous traditional benchmarking efforts (Hendrycks et al., 2021; Sakaguchi et al., 2020) focused on evaluating certain capabilities of models in individual tasks or single-task types. However, with the advancement of LLMs, these benchmarks have become insufficient for comprehensive and accurate assessment of LLM capabilities. Consequently, researchers have proposed more comprehensive and challenging benchmarks (Hendrycks et al., 2020; Li et al., 2023; Huang et al., 2023b) to test whether LLMs possess general world knowledge and reasoning ability. Additionally, there are task-specific evaluations such as LawBench (Fei et al., 2023) and ArcMMLU (Zhang et al., 2023). However, whether in English or Chinese, there is currently a lack of benchmarks for evaluating the musical abilities of LLMs, despite music being an important part of human life. Therefore, we propose ZIQI-EVAL, a benchmark for evaluating the musical abilities of LLMs, to fill the gap in benchmark evaluations of LLMs' musical capabilities.

3 ZIQI-Eval Benchmark

3.1 Dataset Curation

General Principle This dataset integrates the renowned music literature database Répertoire International de Littérature Musicale (RILM), providing a broad research perspective and profound academic insights into the dataset. The inclusion of "The New Grove Dictionary of Music and Musicians" injects the essence of musical humanism into the dataset. Furthermore, dozens of domestic and foreign monographs, such as "Music in Western Civilization" by Paul Henry Lang, the availability of past exam materials from Baidu Wenku, and the advanced data processing capabilities of GPT-4 (Achiam et al., 2023), collectively enhance the data integrity and reliability of the model.

Data Statistics ZIQI-Eval dataset consists of two parts: music comprehension question bank and msuic generation question bank.

The music comprehension question bank which is presented in the form of multiple-choice questions consists of 10 major categories and 56 subcategories, encompassing 14244 data entries. It not only includes traditional classifications such as music performance, composition theory, and world ethnic music, but also covers popular music, Western music history, Chinese music history, Chinese traditional music, music aesthetics, and music education. The topics range from popular music, rock music, blues, to female music and more. Additionally, the dataset adopts a decentralized design philosophy, fully showcasing the diversity and inclusiveness of global music cultures.

The music generation question bank consists of 200 questions, testing the ability of music continuation. Considering the difficulty in the evaluation of the generated music, the music generation questions are also presented in the form of multiple-choice questions.

We conduct a comprehensive evaluation of LLMs' music capabilities across the entire dataset. It is worth mentioning that this music dataset has made positive contributions in highlighting female music composers. By including relevant content about female composers, it addresses the gender imbalance in historical literature and promotes progress and inclusivity in the music academic community. This initiative not only reflects the model's profound recognition of gender equality issues but also demonstrates its efforts in advancing the diversification of the music field.

3.2 Evaluation Criteria

The evaluation is divided into two parts: music comprehension evaluation and music generation evaluation. The music comprehension evaluation aims to assess the LLMs' music comprehension abilities, specifically their understanding of music harmony, melody, and rhythm. The music generation evaluation, on the other hand, seeks to evaluate the LLMs' capacities for music generation, namely their ability to generate music across diverse styles and genres.

Music Comprehension Evaluation We turn the music-related knowledge into the question stem and provide them with options to LLMs, making LLMs to choose the right answer. For example, as shown in Figure 2, take "What is the milestone representative work of Impressionistic orchestral music?" as the stem, "The Sea", "Prelude to the Afternoon of a Faun", "Pelléas et Mélisande", and "Clair de Lune" as the options, we examine whether LLMs can select the right answer "Prelude to the Afternoon of a Faun".

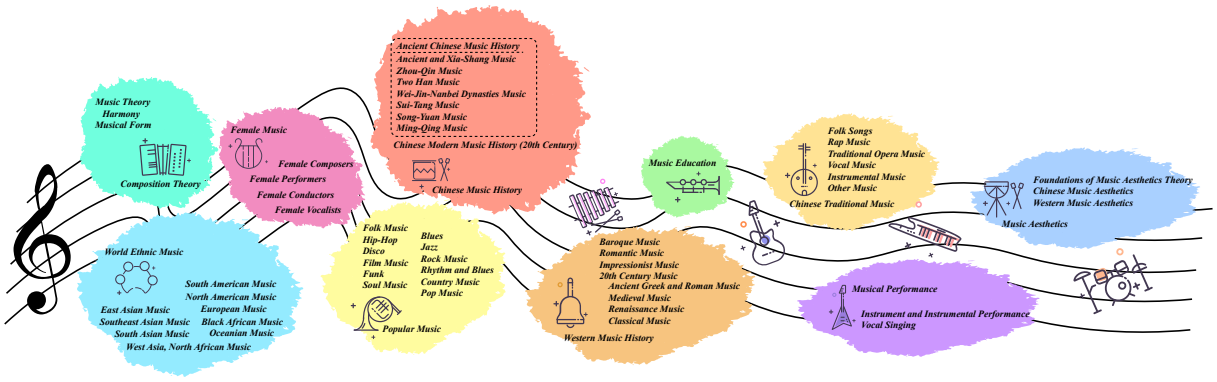

Figure 1: ZIQI-Eval task overview.

Music Comprehension Test
题目：印象主义管弦音乐里程碑式的代表作为____。
Question: What is the milestone representative work of Impressionistic orchestral music?
A.《大海》 "The Sea"
B.《牧神午后》 "Prelude to the Afternoon of a Faun"
C.《佩里亚斯与梅丽桑德》"Pelléas et Mélisande"
D.《月色满庭台》"Clair de Lune"

Music Generation Test
题目：请根据输入的旋律选择最匹配的旋律续写片段：
Question: Please choose the most fitting continuation for the given melody based on the input:
X:3
M:2/4
L:1/8
R:Country Dance
N:"Allegro"
K:D
"Allegro"D/E/|FFFF|F2 dF|{F}EDEF|DA,DE|

Figure 2: Examples of music comprehension and music generation test.

Music Generation Evaluation Given that most LLMs can only accept textual inputs, we utilize ABC notation to convert the musical scores of audio into a textual format, which serves as the input for LLMs. We partition the sheet music written in ABC notation into two segments. The initial segment serves as the question, while the subsequent segment presents four alternative options, also in ABC notation, for the potential continuation of the composition. Then we make LLMs discern the most likely continuation fragment, assessing their music continuation ability. For instance, as shown in Figure 2, we split the original score from "AABB|ccdd|ccBB|A3:|", and test whether LLMs have the ability to choose the most fitting option.

4 Experiments

4.1 Setup

Baselines We comprehensively assess 17 LLMs, including API-based models and open-source models. The API-based models contain GPT-4 (gpt-4-1106-preview) (Achiam et al., 2023), GPT-3.5-Turbo (OpenAI, 2022), Claude-instant-1 (Anthropic, 2022), and ERNIE-Bot (Baidu, 2023) series. The open-source models contain Aquila-7B (WUDAO, 2023), Bloomz-7.1B (Muennighoff et al., 2022), ChatGLM2-6B (THUDM, 2023), Mixtral (Jiang et al., 2024), Qwen-7B-Chat (Bai et al., 2023), XuanYuan-70B (Zhang and Yang, 2023), and Yi-6B (01-ai, 2023).

Metrics We use a regular expression R, namely $r'[ABCD]'$, to match the answer and consider the first uppercase letter $\in$ {'A', 'B', 'C', 'D'} matched as the response. We define Accuracy (Acc.) as the proportion of correctly answered questions among all questions. Precision is the proportion of correctly answered questions among the questions predicted as A/B/C/D. Recall is the proportion of correctly answered questions among the total number of questions that should be answered as A/B/C/D. In this case, the total number of questions that should be answered as A/B/C/D is actually the total number of questions, so the recall metric is equivalent to the accuracy metric. F1 score is the weighted harmonic mean of precision and recall. The specific formulas for these metrics

Models	Music Comprehension Evaluation			Music Generation Evaluation		
	Precision	Recall (Acc.)	F1	Precision	Recall (Acc.)	F1
GPT-4	62.85	100.00	77.19	53.50	97.00	68.96
GPT-3.5-Turbo	-	-	-	30.50	96.00	46.29
Claude-instant-1.2	45.86	71.43	55.86	25.00	99.50	39.96
ERNIE-Bot	49.96	66.69	57.13	29.00	96.50	44.60
ERNIE-Bot-Speed	31.18	74.57	43.97	42.00	100.00	59.15
ERNIE-Bot-Turbo	47.88	94.07	63.46	25.50	100.00	40.64
ERNIE-Bot-8k	53.17	99.16	69.22	26.50	88.00	40.73
Aquila-7B	29.06	62.40	39.65	9.00	40.00	14.69
Bloomz-7.1B	31.97	91.06	47.33	19.00	64.50	29.35
ChatGLM2-6B	39.82	60.52	48.04	15.50	62.50	24.84
Mixtral-8x7B	43.39	99.56	60.44	31.00	100.00	47.33
Qwen-14B	30.04	17.98	22.49	23.66	15.50	18.73
XuanYuan-70B	37.70	46.70	41.72	21.00	89.00	33.98
Yi-6B	60.00	11.06	18.68	0.00	0.00	0.00
Yi-34B	32.24	16.76	22.06	12.12	2.00	3.43

Table 1: Main results(%) of the Music Comprehension Evaluation and Music Generation Evaluation in ZIQI-Eval. Segment 1: API-based models; Segment 2: Open-source models.

are as follows:

$$\tilde{X} = G(X)$$

$$\hat{y} = R\left(\tilde{X}\right)$$

$$Precision = \frac{\sum_{i=1}^{N} \mathbb{I}(\hat{y_i} = y_i)}{V}$$

$$Recall(Acc.) = \frac{\sum_{i=1}^{N} \mathbb{I}(\hat{y_i} = y_i)}{N}$$

$$F1 = \frac{2 * Precision * Recall}{Precision + Recall}$$

where G is the LLM generation process, $\tilde{X}$ is the generated string, $R(\cdot)$ is applying the regular expression for answer retrieval, $\hat{y}$ is the predicted answer, V is the number of questions predicted as A/B/C/D, N is the total number of the questions, and $\mathbb{I}(\cdot)$ is the indicator function.

4.2 Results

Table 1 presents the main results of ZIQI-Eval. Based on the results, we can find that:

I. Overall, the performance of all LLMs on the ZIQI-Eval benchmark is poor. In both music comprehension test and music generation test, the majority of LLMs have not surpassed the passing threshold of 60. Their accuracy rates generally hover between 30 and 50, performing only marginally better than random selection. Even the top-performing model, GPT-4, achieved accuracy rates of only 77.19 and 68.96 in the respective tests. This glaring discrepancy highlights the inadequate consideration given to music accuracy within current LLM models and underscores the formidable challenges posed by the ZIQI-Eval benchmark.

II. API-based models perform better than open-source models. In the evaluation of music comprehension test, API-based models generally exhibit higher accuracy compared to open-source models. The accuracy of API-based models is basically distributed between 50 and 70, while open-source models mostly range between 30 and 50. Only specific open-source models like ChatGLM3 and Mixtral can achieve an accuracy higher than 50.

In the evaluation of music generation questions, API-based models consistently outperform open-source models with significantly higher accuracy. The highest accuracy achieved by an API-based model is 68.96, surpassing the highest accuracy of in open-source models.

III. The music capabilities of LLMs are dependent but not solely on parameter size. There is a certain degree of relationship between the musical ability and parameter size of LLM models within the same series, while the musical ability of LLM models from different series is not strongly correlated with parameter size.

The ChatGLM series, Qwen series, and Yi series LLMs consistently show improvements in both music comprehension and generation accu-

racy. Contrary to expectations, the model with significantly different parameter sizes, ChatGLM2-6B and XuanYuan-70B, exhibits higher accuracy in music comprehension for the ChatGLM2-6B model, surpassing XuanYuan-70B by 6.32. Even among models with similar parameter sizes, there can be considerable differences in performance. For example, the Yi-6B model achieves a music comprehension accuracy of only 28.28, while ChatGLM2-6B achieves an accuracy of 48.04, resulting in a significant difference of 19.76 between the two accuracy rates.

IV. The instruction-following abilities of LLMs are not directly linked to their music capabilities. The recall scores of LLMs are strongly correlated with their instruction-following abilities. However, a strong instruction-following capability does not necessarily indicate strong musical capabilities in LLMs. Some LLMs may score highly in terms of recall, but they struggle to effectively comprehend and generate music. Claude-instant-1 serves as a clear example where the subjective recall score reaches 99.5, but the precision is only equivalent to random selection.

V. The music generation capabilities of LLMs are in need of improvement. Even though some LLMs demonstrate a decent understanding of music, their music generation capabilities still have room for improvement. In general, the accuracy for music generation test in LLMs are lower compared to music comprehension test. The difference can be quite significant, such as ERNIE-Bot-8k, where the score for music comprehension test is higher by 28.49 compared to music generation test.

5 Analysis

In addition to the overall evaluation of LLMs on the dataset, we are also interested in the models' accuracy for specific categories.

5.1 Does LLM show any bias towards questions related to women?

We compare the accuracy of LLMs in the female music theme with the average accuracy obtained by LLMs in the female music theme to analyze whether there is bias in LLMs towards female music. We categorize LLMs into three groups: LLMs without gender bias (above the average accuracy), LLMs with no significant bias (deviating within a range of $\pm 1.0\%$ from the average accuracy), and LLMs with gender bias (below the average accuracy).

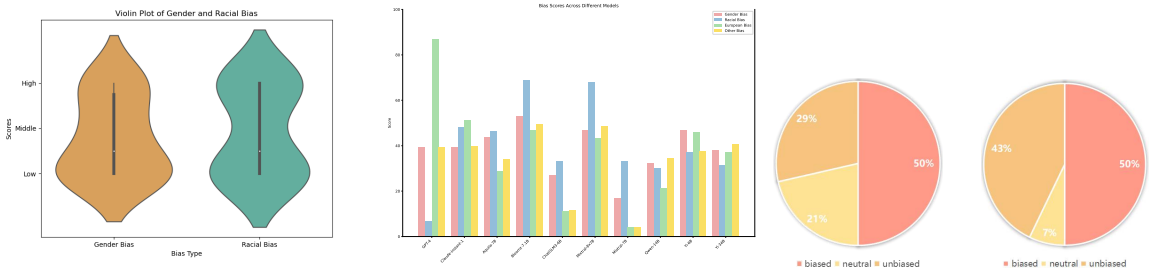
Models	Female	Black	Region	
			European	Other
GPT-4	39.42	6.95	86.95	39.37
Claude-instant-1	39.38	48.00	51.32	40.00
Aquila-7B	43.85	46.29	28.69	34.00
Bloomz-7.1B	53.17	68.83	46.91	49.56
ChatGLM3-6B	27.27	33.33	11.43	11.61
Mixtral-8x7B	46.90	67.86	43.39	48.72
Mistral-7B	17.14	33.33	4.00	4.16
Qwen-14B	32.51	30.30	21.57	34.46
Yi-6B	46.90	37.31	46.02	37.45
Yi-34B	38.26	31.58	37.37	40.77
Average	38.48	40.38	37.77	34.01

Table 2: Results(%) of Female Music Accuracy and Black African Music Accuracy. *Female* stands for Female Music Accuracy, *Black* stands for Black African Music Accuracy, and *Region* stands for the accuracy of LLMs regarding World Ethnic Music.

Because we do not fine-tune LLMs, the results reflect the inherent biases of the LLMs themselves. According to the results of Table 2, 40% of the models have no gender bias, 30% of the models are neutral or have no significant bias, and 30% of the models have gender bias, as shown in Figure 3(c). LLMs with accuracy lower than the average accuracy tend to overlook relevant content related to female music themes. Mistral-7B and ChatGLM3-6B, in particular, have significantly lower scores than the average, indicating a notable gender bias issue in these two models. Overall, LLMs exhibit minimal gender bias.

5.2 Does LLM exhibit bias toward different races?

We calculate the accuracy of LLMs for the subtopic of Black African music, using the same partitioning method as for determining gender bias, to assess whether there is racial bias in LLMs. According to the results of Table 2, 40% of the models have no racial bias, 10% of the models are neutral or have no significant bias, and 50% of the models have racial bias, as shown in Figure 3(c). The accuracy rates of ERNIE-Bot-Speed and Aquila-7B are below the mean by x and y respectively, indicating a significant racial bias in these two models. Overall, LLMs exhibit minimal racial bias.



(a) Distribution (b) accuracy (c) Proportion

Figure 3: Performance of LLMs on gender bias and racial bias.

5.3 Does LLM display bias in terms of region?

We seek to investigate whether LLMs are influenced by Eurocentrism, which positions Europe as the cultural and knowledge center, potentially leading to lower evaluations or neglect of contributions from non-central regions and resulting in biases against these regions. To assess the presence of region bias, we computed the accuracy for the European Music subtheme within World Ethic Music, and the average accuracy for other subthemes within World Ethic Music. Among the LLMs, 30% exhibited higher accuracy rates in European Music compared to other regional music, while 50% of LLMs demonstrated higher accuracy rates in European Music than the average accuracy rate within European Music. These findings suggest that LLMs are influenced by Eurocentrism and exhibit bias towards non-central regions. Most LLMs show similar accuracy between European music and other regions. Surprisingly, GPT-4 exhibits a significantly higher accuracy in European music compared to other regions, with a difference of 47.58, demonstrating a clear bias and regional inclination.

From Figure 3(b), it is evident that LLMs demonstrate similar tendencies towards both gender bias and racial bias, displaying a trend where both ends (with bias and without bias) are relatively higher, while the middle (neutral) is lower. Some LLMs have accuracy rates significantly lower than the mean, such as Aquila-7B with an accuracy rate lower than the mean by 20%, suggesting that LLMs still have a long way to go in eliminating biases. It is worth noting that LLMs with a propensity for gender bias are likely to exhibit racial bias as well, as evidenced by models such as Aquila-7B, ChatGLM2-6B, and Llama-7B. Consequently, it is imperative for future developments in LLMs to address biases comprehensively, not limited to gender and racial biases.

6 Futher Analysis

6.1 Phenomenon Analysis of LLMs

To further explore the subjective capabilities of LLMs in the realm of music, we conducted an in-depth analysis of the responses provided by each model. Our findings categorize the existing LLMs into three distinct types:

I. Lack of melodic understanding: This type includes LLMs that demonstrate a complete lack of comprehension regarding musical notation. When faced with questions that require the continuation of a melody after a format transformation, these models predominantly resort to evasion, often responding with statements like "Unable to determine, need more information." They fail even to understand the format of the input melody. ChatGLM2-6B and Aquila-7B are prototypical examples of this type, characterized by a high frequency of evasive responses, resulting in a significantly low efficacy in their replies. A notable phenomenon is their tendency to "guess" by consistently selecting option A, leading to most responses without any analytical explanation. For instance, in the responses from ChatGLM2-6B, option A was chosen up to 60%. Besides a preference for option A, Aquila-7B also shows a partiality towards option D.

II. Limited appreciation, misaligned with human preferences: A representative model in this type is ERNIE-Bot-8K. This model provides highly interpretable analyses for each option of every question, offering seemingly logical explanations concerning melody, rhythm, and pitch. However, the model's performance, with accuracy barely exceeding that of random selection, underscores the challenge of encapsulating the subjective essence of music appreciation through algorithmic processes. This discrepancy not only highlights the limitations

of current AI models in understanding complex, subjective domains but also underscores the need for more sophisticated approaches that can better capture the intricacies of human preferences.

III. Relatively good appreciation skills: GPT-4 stands out as a typical example of this type. Its responses consider aspects such as melodic coherence, stylistic similarity, and the seamless integration of musical structures, aligning to a certain extent with human preferences. Further analysis of the questions GPT-4 answered incorrectly revealed a strong inclination towards musical continuity. In many instances, it was observed that GPT-4 prioritized coherence, which led to the selection of incorrect options.

6.2 Analysis of GPT-4

Taking GPT-4 as a case study, we have gained further insights into the performance of LLMs in the realm of music. The performance of GPT-4 in the domains of women's music and world ethnic folk music indicates a commendable understanding of specific musical areas, reflecting GPT-4's focus on diversity and inclusivity. Women's music and world ethnic folk music, each representing unique cultural and social perspectives, have shown through GPT-4's relatively higher scores the extensive coverage of different cultures and musical traditions.

GPT-4 has demonstrated exceptional performance in the realm of popular music, achieving scores close to 90. This may be due to the abundant and accessible resources in popular music, including lyrics, genres, and artist information. The popularity and media coverage of pop music may also have facilitated the model's learning efficiency in this field.

It has also scored highly in Western music history and music performance, showcasing its capability in processing music history and practical music-making. The higher scores in Western music history over all other regions suggest a certain degree of geographical bias.

In the area of music aesthetics, GPT-4 scored low, revealing a significant weakness. This may be attributed to the complexity and subjectivity of music aesthetics, which might surpass the model's ability to learn from existing textual materials, indicating that there is room for improvement in the model's perception, evaluation, and theoretical analysis of music.

Through analysis, we identified that GPT-4 tends to make errors in several distinct categories, primarily falling into three types:

Matching Errors: This category encompasses questions related to musical knowledge, specifically matching-type queries, such as identifying the first Hungarian national opera or the composer of "The Song of the Red Flag". GPT-4's responses often affirmatively stated incorrect options, indicating inaccuracies within its knowledge base for specific factual information.

Comprehension Errors: These errors involve understanding specific musical terminologies and the relationships between certain concepts. Questions like "What function of art does edutainment refer to?" or "What role do work songs play in labor as a genre of folk music?" exemplify where GPT-4 misinterprets multiple word meanings, leading to a misunderstanding of the intended concept. This suggests a need for improvement in GPT-4's understanding and reasoning within the musical domain.

Reasoning Errors: In instances where GPT-4 correctly understands the question and possesses the relevant knowledge background, errors occur during the reasoning or calculation process, resulting in incorrect conclusions. An example can be seen in questions involving the calculation of musical intervals, where GPT-4 confuses semitones and whole tones. This indicates a gap in GPT-4's ability to perform downstream tasks that require precise logical deductions.

7 Conclusion and Future Work

Our research sheds light on the oversight of existing evaluations in recognizing the musical abilities of large models. To address this gap, we introduce ZIQI-Eval, a comprehensive benchmark that encompasses 10 major categories and 56 subcategories, comprising over 14,000 data entries. Notably, this benchmark also actively contributes to the acknowledgment of female music composers, rectifying the gender disparity and promoting inclusivity. We conduct a comprehensive experiment involving 15 LLMs, including both API-based and open-source models, to assess their performance in the domain of music. The results indicate that there is significant scope for enhancing the musical capabilities of existing LLMs. We intend to create a multimodal benchmark to evaluate the musical expertise of LLMs in the future.

Limitations

Our research to date has been exclusively focused on objective questions, without delving into the study of subjective questions. One limitation of our current music benchmark is the absence of multimodal data. While the benchmark may excel in evaluating and comparing the quality and creativity of musical compositions based on audio data alone, it fails to incorporate other essential aspects of the music experience, such as visual elements or textual information.
