Fast and Robust Link Prediction using Ontology

Anonymous ACL submission

Abstract

Link Prediction is the task of predicting missing relations between knowledge graph entities (KG). Recent work in link prediction mainly attempted to adapt a model for increasing link prediction accuracy by using more layers in neural network architecture, which heavily rely on computational resources and are not scalable on big KGs. This paper proposes a method of refining knowledge graphs to perform link prediction operations more accurately using relatively fast translational models. Translational link prediction models, such as TransE, TransH, TransD, RotatE, and HAKE, have significantly less complexity than deep learning approaches. Our method uses the ontologies of knowledge graphs to add information as auxiliary nodes to the graph. Then, these auxiliary nodes are connected to ordinary nodes of the KG that contain auxiliary information in their hierarchy. Our experiments show that our method can significantly increase the performance of translational link prediction methods in Hit@10, Mean Rank, Mean Reciprocal Rank.

1 Introduction

Knowledge graphs (KGs) represent a set of interconnected descriptions of entities, including objects, events, or concepts. These graphs are structures by which knowledge is captured in the form of triplets. These triplets consist of three parts: head, relation, and tail. The relation (edge) determines the type of relationship between head and tail nodes. These graphs are becoming a popular approach to displaying and modeling different information in the world.

Despite many efforts to build KGs, they are far from completeness. The incompleteness of KGs has motivated researchers to add information to the graph to complete or update it. One of the developing fields in completing KGs is link prediction (LP). LP tries to embed entities and relations in a small continuous vector space to predict missing

links in KGs. In the last few years, deep learning approaches have significantly outperformed other methods in LP, but this accuracy came at the cost of computational complexity and unscalability.

Translational LP models, such as TransE (Bordes et al., 2013), TransH (Wang et al., 2014), TransD (Ji et al., 2015), RotatE (Sun et al., 2019), and HAKE (Zhang et al., 2020), generally use a straightforward function over head and relation vectors to predict the tail based on distance (Rossi et al., 2021) (Wang et al., 2021). The advantages of translational methods over deep learning techniques are that they are robust, and their score function is considerably faster (Lv et al., 2018). Therefore, in this work, we tried to improve these translational methods.

Ontologies are concepts or properties to describe an object ¹. Wordnet contains hierarchical ontology only for its entities. Some work tried to use ontology components of Wordnet to boost LP models. For example, GrCluster (Ranganathan et al., 2020) treated ontology components as paths. It defined path similarity over entities in Wordnet and slightly improved LP accuracy. Nonetheless, GrCluster only improved WNNH and WN18, which are not standard LP datasets (Dettmers et al., 2018). Additionally, this work is limited to Wordnet.

Freebase (Bollacker et al., 2008) does not have any hierarchical path for its entity. On the other hand, its relations have a path hierarchy to explain edges. SACN (Shang et al., 2019) exploited additional information of FB15k-237 as auxiliary nodes and created FB15k-237-Attr. Nevertheless, it added numerous nodes to the KG, which makes the method for creating FB15k-237-Attr unscalable for more extensive graphs. Likewise, this method can only be applied to Freebase.

Translational LP models, such as TransE, RotatE, or TransD, when trying to learn the relation between Paris and France, neglect that Paris is a

¹https:en.wikipedia.orgwikiOntology_(information_science)

city and France is a country. We introduce ontology components as auxiliary nodes. These auxiliary nodes are connected to related entities that have these components in their hierarchy. For example, we added an extra node "country" to KG and connected it to all the countries in the KG. Our contributions are as follows:

Firstly, we presented a method for refining KGs that have ontology. Our approach adds auxiliary nodes, which increases the accuracy of translational link prediction with the same time and space complexity of translational models. **Secondly**, we used state-of-the-art translational models to evaluate our method on two FB15k-237 and WN18RR. The results showed that accuracy in link prediction was significantly increased on H@10, MRR, and MR.

2 Related Work

We divided related works into four categories.

First, translational models, such as TransE (Bordes et al., 2013), TransH (Wang et al., 2014), TransD (Ji et al., 2015), HAKE (Zhang et al., 2020), are distance-based algorithms that use a straightforward operation over head and relation (mainly summation and/or a projection into a secondary space) to measure the distance to the tail entity. Some work has been introduced over these fast translational models to improve their performance by using hierarchical information. TKRL (Xie et al., 2016) used components of hierarchical structure as a transition to transform KG nodes into secondary space and then performed LP. GrCluster (Ranganathan et al., 2020) used path similarity over entities in Wordnet and slightly improved link prediction accuracy. SACN (Shang et al., 2019) proposed FB15k-237_Attr that has external resources as triplets (new nodes and edges) to improve the result.

GrCluster could not improve the WN18RR, and it is limited to KGs that have ontology for their entities. SACN improved FB15k-237 by creating FB15k-237_Attr, but it added many nodes and edges. Nonetheless, the SACN attribute creator could not be applied to WN18RR. TransC (Lv et al., 2018) brought similar entities closer in the embedding space and improved LP in YAGO, but experiment results show no improvements on Wordnet or Freebase. Our work is similar to this category; It is fast and uses translational models as a core. We pushed the limitation of TransC to have a better LP result on Freebase and Wordnet.

Second, mostly deep models adapt an architecture and rarely use anthologies in their main model. For example, ConvE (Dettmers et al., 2018) used 2D convolution, BERT-ResNet (Lovelace et al., 2021) and KG-BERT (Yao et al., 2019) employed BERT, SACN (Shang et al., 2019) utilized WGCN in its architecture. These models are accurate but computationally costly.

Thirdly, KG refinement is a sub-field of KG enhancement. Refinement can be done by either adding information to the graph or removing incorrect data (Paulheim, 2017). BioKG (Zhao et al., 2020) worked on medical KGs and has tried to provide a method for removing the inaccurate information in these graphs. In this work, like SACN, we added auxiliary nodes to KGs. These nodes are extracted from ontology hierarchy levels of nodes and edges of KGs.

Lastly, some works introduced similarities over entities or relations. For example, HRS (Zhang et al., 2018) presented relation-cluster and subrelations in the scoring function of translational models. It created sub-relations and relationclusters based on clustering results of TransE relations; however, it cannot utilize ontology nor improve WN18RR results. For entity similarity, ETE (Moon et al., 2017) considered that if two entities are embedded closely in the embedding space, they are similar and assigned classes to entities based on closeness. Unlike ETE, our hypothesis is that if two entities use the same relation type in the graph or have common elements in their hierarchies, they are related. We exploited these affiliations (share hierarchical components) by connecting ordinary nodes to their auxiliary nodes if a node has the auxiliary node in its ontology components.

The main distinctions between our work and related work are: First, our method works with any KG with ontology, and it does not matter if it has the hierarchical ontology for nodes or edges. Second, it uses translational models; therefore, it has high speed, and low memory is needed for the algorithm.

3 KGRefiner

In this work, we propose a method that adds information to KGs, which refines the KG and increases LP accuracy. In FB15k-237, we do this refinement by using relation hierarchies, and in WN18RR, we use hierarchies of entities. We add repetitive components of hierarchies to KGs as new (auxiliary)

Dataset	FB15k-237	FB15k-237-Refined	WN18RR	WN18RR-Refined	FB15k-237-Attr

Val. Edges	17535	17535	3034	3034	17535
Test Edges	20466	20466	31134	31134	20466

Table 1: Statistics of the experimental datasets. The refined version represents that graph has some auxiliary nodes. These auxiliary nodes are extracted from entities hierarchy in the original knowledge graph.

nodes. We introduce a few new relations to connect these auxiliary nodes to other KG nodes.

Suppose E as the collection of all knowledge graph entities and R set of all its relations. The (e_s, r, e_o) is called a triplet. The $e_s \sim$ E is the head, and $e_o \sim E$ is the tail of a triplet. Finally, $r \sim R$ represents the relation between e_s and e_o .

Translational link prediction methods such as TransE (Bordes et al., 2013), TransH (Wang et al., 2014), TransD (Ji et al., 2015), etc., create transition property in their embeddings. For example, in TransE, embeddings are made as follow:

$$\vec{e_s} + \vec{r} \approx \vec{e_o} \tag{1}$$

This means the tail entity should be close to the sum of head and relation in embedding space. For example, let us consider these triplets:

$$\vec{Paris} + \vec{capitalof} \approx \vec{France}$$
 (2)

$$Te\vec{hran} + capi\vec{talof} \approx I\vec{ran}$$
 (3)

Translational link prediction models are not aware that both tails entities are countries. If we add a new node as "country" to the graph and connect it to all graph's countries with a new relation "RelatedTo", then these triplets are added to the KG:

$$\vec{France} + \vec{RelatedTo} \approx \vec{country}$$
 (4)

$$\vec{Iran} + RelatedTo \approx country$$
 (5)

Equations 4 and 5 have similar variables; therefore, the loss function brings the embeddings of France and Iran closer, which are semantically similar. This closeness causes the model to search first between countries when it is asked what the capital of France is in the evaluation Equation 2.

3.1 Refinement of FB15k-237

In FB15k-237, graph relations reflect information about entities. For example, in (Paris, national_capital, France), national_capital has hierarchy of "entity \rightarrow physical_entity \rightarrow object \rightarrow location \rightarrow region \rightarrow area \rightarrow center \rightarrow seat \rightarrow

capital \rightarrow national_capital". This hierarchy is a relationship between countries and their capitals, and nodes on one side of relationships (e.g. left side of triplet) can be considered similar (e.g. they are countries).

Moreover, higher hierarchy levels usually have more abstract information about objects, but the lower ones are more specific. Therefore, we extracted the last three levels of hierarchies from each relation in this KG to use hierarchy components. Then, for each sub-relation (component), we counted the number of their repetitions in the KG training section triplets. Then, we removed those components with less than 100 repetitions to reduce the number of these components; the number 100 is arbitrary. Finally, 285 sub-relations remained, and we added them to the set of entities in this KG (as auxiliary nodes). We defined two new relations, "RelatedTo" and "HasAttribute", to connect these relation-nodes (auxiliary nodes) to the KG entities. For each triplet, if the entity is the triplet's head, we link it to the auxiliary node by "RelatedTo", and if it is the tail of the triplet, we use "HasAttribute" to establish these connections. For example, to refine relation between Paris and France, (Paris, entity \rightarrow physical_entity \rightarrow object \rightarrow location \rightarrow region \rightarrow area \rightarrow center \rightarrow seat → capital → national_capital, France), "capital" has repetition over 100, so the following triplets

3.2 Refinement of WN18RR

were added to the graph:

To refine this graph, we use the hierarchy of entities. In Freebase, we used relationships, but relationships do not give us information about entities in Wordnet. France, for example, has a hierarchy of "existence \rightarrow place \rightarrow region \rightarrow region \rightarrow administrative region \rightarrow country". This hierarchy gives us good information about France. We extract the last three levels of entities. Among these

levels, we hold those with more than an arbitrary number of 50 repetitions among entities to reduce the number of auxiliary nodes. As a result, 207 levels remained. We add these levels as new nodes to the KG training section and connect them to entities that have these components in their hierarchy with a new type of connection "HasAttribute". For example, France and Iran have a "country" in their hierarchical structure. Then, the following triplets were added to the training section of the graph:

(France, HasAttribute, country)(Iran, HasAttribute, country)

4 Exprement

4.1 Datasets

We evaluated our work on popular benchmarks: FB15k-237 and WN18RR. In addition, we built two other datasets with KGRefiner: FB15k-237-Refined and WN18RR-Refined from those datasets. The details of the datasets are available in Table 1.

Baseline	11@10	MR	MRR
Basenne	H@10	MK	1,1111
TransE	45.6	347	29.4
TransE + Attribute	47.6	221	28.8
TransE + KGRefiner	47	203	29.1
HAKE	40.8	282	23.8
HAKE + Attribute	38.4	287	21.7
HAKE + KGRefiner	39.0	267	21.4
RotatE	47.4	185	29.7
RotatE + Attribute	43.8	218	27.3
RotatE + KGRefiner	43.9	226	27.9
TransH	36.6	311	21.1
TransH + Attribute	47.7	237	28.2
TransH + KGRefiner	<u>48.9</u>	221	<u>30.2</u>

Table 2: Link prediction results on FB15k-237 and its refined version.

4.2 Baselines

To demonstrate the effectiveness of our models, we compare results with the original translational models TransE (Bordes et al., 2013), TransH (Wang et al., 2014), RotatE (Sun et al., 2019), and HAKE (Zhang et al., 2020), with fair setting (see Appendix A). In addition, we used FB15k-237-Attr (Shang et al., 2019) to compare our work with other data augmentation methods as base models plus attributes.

For WN18RR, GrCluster (Ranganathan et al., 2020) tried to improve link prediction on Wordnet by using hierarchical data using path similarity. Nevertheless, their report did not show improvement in WN18RR.

4.3 Experimental Results

Table 2 and 3 compares the experimental results of our KGRefiner plus translational models and with previously published results. Results in bold font are the best results in the group, and the underlined results denote the best results in the column. KGRefiner with TransH obtains the highest H@10 and MRR on FB15k-237, and also KGRefiner with RotatE reached the best MR and H@10 in WN18RR.

In tables, results of TransE is taken from (Nguyen et al., 2018), TransH and TransD from (Zhang et al., 2018). For other rows, we used OpenKE (Han et al., 2018) and original HAKE implementation to get the scores.

Baseline	H@10	MR	MRR
		1,111	
TransE	50.1	3384	22.6
TransE + KGRefiner	53.7	1125	22.2
TransH	42.4	5875	18.6
TransH + KGRefiner	51.4	1534	20.8
HAKE	52.2	4433	40.0
HAKE + KGRefiner	53.8	2125	25.0
RotatE	54.7	4274	<u>47.3</u>
RotatE + KGRefiner	<u>57.0</u>	683	44.8

Table 3: Link prediction results on WN18RR and its refined version.

5 Conclusion and Future work

In this paper, we propose KGRefiner, a KG refinement method that alleviates the limitations of translational models by capturing additional information in knowledge graph hierarchies. We used hierarchy components as auxiliary nodes. Refined KG comes by connecting these auxiliary nodes to proper entities. Our experimental results show that our KGRefiner outperforms other state-of-the-art translational models and other data augmentation methods on two benchmark datasets, WN18RR and FB15k-237. Furthermore, it is the first augmentation method that works with both Wordnet and Freebase, while old methods only perform only on one dataset.

In future works, we will expand our work on datasets that can be formulated on the triplet structure. For example, recommender system datasets can be formed on graph schema, and KGRefiner can be applied. Additionally, KGRefiner cannot improve the accuracy of deep learning methods; therefore, another study is needed to enhance deep models by using ontological information.

A Hyperparameter Settings

We employed the implementation of baselines by OpenKE (Han et al., 2018), and HAKE (Zhang et al., 2020) to produce the result.

To have a fair comparison between translational models, we used an embedding dimension of 200 for all models (to produce the same result as in their paper, some models need more than 1000 dimensions for entity embedding). Also, we removed self adversarial negative sampling from TransE, RotatE, and HAKE and replaced it with typical negative sampling. Moreover, we tried {200, 500, 1000, 2000} epochs, and we picked the best one according to MRR on the validation set for final comparison. Other hyperparameters of the models are those mentioned in OpenKE and HAKE. Hyperparameters for FB15k-237 and FB15k-237-Refined and also WN18RR and WN18RR-Refined are the same. Interestingly, HAKE heavily relied on 1000 embedding dimensions to reproduce the result on its paper.

B Speed of Models

The training time of translational models is much less than deep learning approaches such as ConvE, SACN, ConvKB, etc. The complexity of scoring function and neural network layers in their architecture reduces training speed in deep learning methods. Table 4 compares the time that each model needs to be trained for one epoch on FB15k-237. We ran models on Nvidia K80. For fair comparison embedding dimension for all models is 200. It can be observed that the runtime difference between HAKE and ConvKB for a small dataset FB15k-237 is around 2.5×10^3 s.

Apart from that, according to table 1, KGRefiner adds triplets to the training section of these KGs. Therefore, it only increases the training time of WN18RR and FB15k-237 by a factor of 2.65 and 2.02, respectively. It does not increase other measurements' complexity because it adds few nodes to the KGs. Consequently, the training cost of the translational models with KGRefiner is still much cheaper than deep learning techniques.

C Limitations

KGRefiner needs a KG that has ontology for either its nodes or edges. Therefore, in other developing KGs, KGRefiner cannot be applied. In addition,

Model	Time to train
TransE (Bordes et al., 2013) [⊕]	$2.8 \times 10^{3} \text{ s}$
TransH (Wang et al., 2014) [⊕]	5.2×10^3 s
TransD (Ji et al., 2015) [⊕]	5.2×10^3 s
RotatE (Sun et al., 2019) [⊕]	5×10^3 s
HAKE (Zhang et al., 2020) [⊕]	1.5×10^{4} s
ConvE	
(Dettmers et al., 2018) $[\ominus]$	2.7×10^{5} s
ConvKB	
(Nguyen et al., 2018) $[\ominus]$	4×10^4 s
BERT-ResNet	
(Lovelace et al., 2021) $[\ominus]$	$9.7 \times 10^4 s$

Table 4: Comparison between translational technique and deep learning methods in training time. $[\oplus]$: These models are implemented by OpenKE (Han et al., 2018) and $[\ominus]$ are produced by their original implementations.

since it brings similar entities closer, this can only improve distance-based models (translational).

D Scailability

Regarding the scalability of KGRefiner, it should be said that for some settings limitation is the number of nodes because their embeddings that have to be stored in memory. Since KGRefiner adds a few numbers of auxiliary nodes and one or two relations, this can easily be applied to other KGs. However, SACN adds many nodes and relation types. So unlike KGRefiner, the SACN method is not practical for larger KGs.
