Memorize Step by Step: Efficient Long-Context Prefilling with Incremental Memory and Decremental Chunk

Anonymous ACL submission

Abstract

 The evolution of Large Language Models (LLMs) has led to significant advancements, with models like Claude and Gemini capa- ble of processing contexts up to 1 million to- kens. However, efficiently handling long se- quences remains challenging, particularly dur- ing the prefilling stage when input lengths ex- ceed GPU memory capacity. Traditional meth- ods often segment sequence into chunks and compress them iteratively with fixed-size mem- ory. However, our empirical analysis shows that the fixed-size memory results in wasted computational and GPU memory resources. 014 Therefore, we introduces Incremental Memory (IM), a method that starts with a small mem-**ory size and gradually increases it, optimiz-** ing computational efficiency. Additionally, we propose Decremental Chunk based on Incre- mental Memory (IMDC), which reduces chunk size while increasing memory size, ensuring stable and lower GPU memory usage. Our experiments demonstrate that IMDC is consis- tently faster (1.45x) and reduces GPU memory 024 consumption by 23.3% compared to fixed-size memory, achieving comparable performance on the LongBench Benchmark.

027 1 Introduction

 The evolution of Large Language Models (LLMs) has reached new frontiers, with models like Claude [\(Anthropic,](#page-8-0) [2024\)](#page-8-0) and Gemini [\(Reid et al.,](#page-9-0) [2024\)](#page-9-0) capable of processing contexts spanning up to a 1 million tokens. However, the efficiency of process- ing long sequences with LLM still faces significant challenges.

 The inference of LLM can be divided into two parts: Prefilling and Decoding. LLM inference for long documents faces significant challenges in both stages. In the prefill stage, the model needs to read long sequences and endure the quadratic complexity of attention calculations with respect to the sequence length. During the decoding stage,

Figure 1: (a): The average attention scores of memory at each step. (b): The distribution of memory content across chunks, where we count the number of key-value pairs in memory originating from each chunk. For both Figure (a) and (b), we used KV Cache pruner (SnapKV [\(Li et al.,](#page-9-1) [2024\)](#page-9-1) and StreamingLLM [\(Xiao et al.,](#page-10-0) [2023\)](#page-10-0)) to compress memory and chunk.

decoding each token requires accessing the sub- **042** stantial Key-Value (KV) Cache generated in the **043** prefill stage. Most efforts to optimize the efficiency **044** of LLM for long sequence focus on the decoding **045** stage, particularly on compressing the KV Cache **046** [\(Xiao et al.,](#page-10-0) [2023;](#page-10-0) [Zhang et al.,](#page-10-1) [2023;](#page-10-1) [Liu et al.,](#page-9-2) **047** [2024c;](#page-9-2) [Hooper et al.,](#page-9-3) [2024;](#page-9-3) [Liu et al.,](#page-9-4) [2024a;](#page-9-4) [Sun](#page-9-5) **048** [et al.,](#page-9-5) [2024\)](#page-9-5). However, when the input length **049** during the prefilling stage exceeds the maximum **050** length supported by GPU memory capacity, even **051** [p](#page-8-1)refilling cannot proceed. Existing works [\(Bulatov](#page-8-1) **052** [et al.,](#page-8-1) [2023a](#page-8-1)[,b;](#page-8-2) [Ge et al.,](#page-9-6) [2023b;](#page-9-6) [Liu et al.,](#page-9-7) [2020;](#page-9-7) **053** [Munkhdalai et al.,](#page-9-8) [2024\)](#page-9-8) tackle this problem by **054** dividing the sequence into chunks and iteratively **055** compress these chunks with a fixed-size buffer as **056** memory. 057

Our anlysis on the memory displayed in [Figure 1](#page-0-0) **058** reveals that: 1) the attention scores of memory **059** starts at a relatively low value and gradually in- **060** creases throughout the prefill process [\(Figure 1a.](#page-0-0)), **061** which suggests that early-stage memory has min- 062 imal influence on the next-step computation; 2) **063** once the prefill phase concludes, the memory dis- **064** tribution is primarily concentrated at the end of the **065** sequence [\(Figure 1b\)](#page-0-0), implying that most of the 066

067 early-stage memory is not retained by the end of **068** the prefill.

 Overall, our finding suggest that the early-stage memory in the prefill phase is less impactful com- pared to the later-stage memory. Therefore, it is unnecessary to maintain a large memory size at the early stage of prefilling. This implies that ap- proaches [\(Bulatov et al.,](#page-8-1) [2023a](#page-8-1)[,b;](#page-8-2) [Ge et al.,](#page-9-6) [2023b;](#page-9-6) [Munkhdalai et al.,](#page-9-8) [2024\)](#page-9-8) that maintain a fixed-size buffer to compress long sequences may result in wasted computational and memory resources.

 To avoid computational waste during the early 079 stage of prefilling, we propose **Incremental Mem-ory** (IM), which starts with a small memory size and gradually increases it until the end of the pre- filling phase. During this growth phase, the mem- ory size of IM remains smaller than the maximum length, resulting in greater efficiency compared to the commonly used fixed-size memory.

 While analyzing memory distribution across dif-**ferent layers^{[1](#page-1-0)}**, we observed that higher layers ex- hibit a more uniform memory distribution com- pared to lower layers. Consequently, we propose an adaptive memory growth strategy to set mem- ory sizes for each layer based on the proportion of memory retained after compression, with lay- ers retaining more memory being allocated larger memory sizes.

 Although IM is faster than fixed-size memory, it does not significantly reduce peak GPU memory usage, as the memory size of IM is the same as that of fixed-size memory at the end of the prefill- ing phase. Therefore, we propose Decremental Chunk based on Incremental Memory (IMDC), which starts with a large chunk size that decreases as memory size increases. When the memory size is small, the chunk size is large, and vice versa. The incremental memory and decremental chunk strate- gies complement each other, maintaining stable GPU memory usage that is lower than fixed-size memory, which is illustrated in Figure [2.](#page-1-1)

 Our experiments show that IMDC is consistently faster (1.45x) than fixed-size memory and con- sumes less GPU memory (23.3% reduction) during the prefill stage, yielding comparable results on LongBench Benchmark [\(Bai et al.,](#page-8-3) [2023\)](#page-8-3).

113 Our main contributions are as follows:

114 • Our analysis on memory reveals that, the **115** early-stage memory in the prefilling is less **116** impactful than the later-stage memory.

Figure 2: The illustration of Fixed-Size Memory, Incremental Memory (IM) and Incremental Memory with Decremental Chunk (IMDC).

- Based on this finding, we propose the In- **117** cremental Memory and Decremental Chunk **118** (IMDC) approach, which dynamically in- **119** creases memory size while decreasing chunk **120 size.** 121
- Our experiments demonstrate that IMDC is **122** 1.45 times faster than the commonly used **123** fixed-size memory and consumes 23.3% less **124** GPU memory during the prefill stage, with- **125** out sacrificing performance on long-context **126** benchmarks. **127**

2 Related Works **¹²⁸**

The long-context efficiency of LLM has been **129** widely studied, which can be classified into two **130** categories: prefilling and decoding. **131**

Prefilling The prefilling of LLM encounters 132 quadratic complexity in attention calculations with **133** respect to sequence length. Numerous research **134** efforts have sought to reduce this quadratic com- **135** plexity through methods such as low-rank approx- **136** imation [\(Wang et al.,](#page-10-2) [2020;](#page-10-2) [Peng et al.,](#page-9-9) [2021;](#page-9-9) **137** [Choromanski et al.,](#page-8-4) [2020\)](#page-8-4) and sparsification [\(Child](#page-8-5) **138** [et al.,](#page-8-5) [2019;](#page-8-5) [Vyas et al.,](#page-10-3) [2020;](#page-10-3) [Kitaev et al.,](#page-9-10) [2020\)](#page-9-10). **139** [Tay et al.](#page-9-11) [\(2023\)](#page-9-11) provided a comprehensive re- **140** view of these approaches. These methods mod- **141** ify the computation mode of attention, often re- **142** sulting in a trade-off with model performance. In 143 contrast, flash attention [\(Dao et al.,](#page-8-6) [2022\)](#page-8-6) identi- **144** fied that the efficiency bottleneck lies primarily in **145** input/output (I/O) operations rather than compu- **146** tational processes. By implementing CUDA op- **147** erations, they significantly accelerated attention **148** calculations without altering the fundamental com- **149** putation of attention. RMT [\(Bulatov et al.,](#page-8-1) [2023a\)](#page-8-1) **150** proposed an iterative compression scheme for long **151** texts, maintaining and dynamically updating a **152** [fi](#page-8-2)xed-size memory, which is followed by [\(Bula-](#page-8-2) **153** [tov et al.,](#page-8-2) [2023b;](#page-8-2) [Ge et al.,](#page-9-6) [2023b;](#page-9-6) [Liu et al.,](#page-9-7) [2020;](#page-9-7) **154** [Munkhdalai et al.,](#page-9-8) [2024\)](#page-9-8). AutoCompressors [\(Liu](#page-9-7) **155**

¹The results are shown in Figure 6

[Figure 3: The illustration of iterative compression with Fixed-Size Memory \(FM\), Incremental Memory \(IM\) and](#page-9-7) [Decremental Chunk based on Incremental Memory \(IMDC\). The iterative compression involves multiple steps of](#page-9-7) [compression on the KV cache of memory and chunk.](#page-9-7)

 [et al.,](#page-9-7) [2020\)](#page-9-7) also introduced incremental memory, but different from our method, they increase mem- ory size to enhance the model performance, which results in significant overhead. We demonstrate the superiority of our method compared to AutoCom-pressors empirically in Appendix [B.2.](#page-11-0)

 Decoding Most efforts to optimize the efficiency of long-context decoding have focused on KV Cache compression. Research in this area can [b](#page-10-1)e categorized into KV Cache Pruning [\(Zhang](#page-10-1) [et al.,](#page-10-1) [2023;](#page-10-1) [Xiao et al.,](#page-10-0) [2023;](#page-10-0) [Liu et al.,](#page-9-12) [2023\)](#page-9-12), [l](#page-8-7)ow-rank approximation [\(Shazeer,](#page-9-13) [2019;](#page-9-13) [Ainslie](#page-8-7) [et al.,](#page-8-7) [2023;](#page-8-7) [Shao et al.,](#page-9-14) [2024\)](#page-9-14), quantization [\(Liu](#page-9-2) [et al.,](#page-9-2) [2024c;](#page-9-2) [Hooper et al.,](#page-9-3) [2024;](#page-9-3) [Liu et al.,](#page-9-15) [2024b\)](#page-9-15), and layer sharing [\(Liu et al.,](#page-9-4) [2024a;](#page-9-4) [Sun et al.,](#page-9-5) [2024;](#page-9-5) [Brandon et al.,](#page-8-8) [2024\)](#page-8-8). Key works in KV Cache pruning include H2O [\(Zhang et al.,](#page-10-1) [2023\)](#page-10-1) and StreamingLLM [\(Xiao et al.,](#page-10-0) [2023\)](#page-10-0). H2O se- lects important KVs based on cumulative attention scores, while StreamingLLM retains only the KVs closest to the end of the sequence. Subsequent [w](#page-8-10)orks [\(Oren et al.,](#page-9-16) [2024;](#page-9-16) [Ge et al.,](#page-8-9) [2023a;](#page-8-9) [Dong](#page-8-10) [et al.,](#page-8-10) [2024;](#page-8-10) [Ren and Zhu,](#page-9-17) [2024;](#page-9-17) [Li et al.,](#page-9-1) [2024\)](#page-9-1) proposed several improvements to H2O, all of which determine KV importance based on attention scores. Notable approaches for low-rank approx- imation include multi-query attention [\(Shazeer,](#page-9-13) [2019\)](#page-9-13) and grouped query attention [\(Ainslie et al.,](#page-8-7) [2023\)](#page-8-7), where different queries share the same KVs. Layer sharing methods [\(Liu et al.,](#page-9-4) [2024a\)](#page-9-4) identify redundancy among the KV Caches of different layers, retaining only the KVs of certain layers. Quan- **187** tization compression [\(Liu et al.,](#page-9-2) [2024c\)](#page-9-2) reduces KV **188** Cache precision from fp16 to int8 through various **189** quantization methods [\(Dettmers et al.,](#page-8-11) [2022\)](#page-8-11). **190**

In this paper, we adopted the iterative compres- **191** sion method from RMT. However, unlike RMT **192** [\(Bulatov et al.,](#page-8-1) [2023a\)](#page-8-1), which compresses se- **193** quences into Soft Tokens, we used StreamingLLM **194** and SnapKV to compress KV Cache, because they **195** do not require training and can maintain a constant **196** memory size during the iteration. **197**

3 Method **¹⁹⁸**

3.1 Iterative Compression **199**

When the input sequence length during the prefill 200 stage exceeds the maximum length supported by **201** the GPU memory limit, the sequence is segmented **202** into multiple chunks and compressed iteratively, as **203** illustrated in [Figure 3.](#page-2-0) In each iteration, the LLM **204** reads the memory as the KV cache for attention. **205** After the attention computation, the newly gener- **206** ated KV cache is sent to the compressor, which **207** updates the memory. **208**

The process of iterating through chunks is simi- **209** lar to a recurrent neural network, while the compu- **210** tation within each chunk operates in parallel, akin **211** to a transformer.^{[2](#page-2-1)}

212

 2 The intriguing intersection between KV Cache Pruning and recurrent neural networks is also discussed in [Oren et al.](#page-9-16) [\(2024\)](#page-9-16).

213 3.2 Incremental Memory

 Based on the finding from [Figure 1](#page-0-0) that it is un- necessary to keep a large memory size at the early stage of prefilling, we propose Incremental Mem- ory (IM), which increases memory size during the iteration of compression. We explore various incre- mental functions to increase memory size: Linear Function (Section [3.2\)](#page-3-0), Adaptive Function (Sec- tion [3.2\)](#page-3-1), and other increasing functions detailed in Appendix [A.1.](#page-11-1)

223 Linear Function Suppose the number of chunks 224 is *n*, the memory size increase from m_0 to m_{max} **225** linearly:

$$
m_i = \frac{(m_{\text{max}} - m_0)i}{n - 1} + m_0, \tag{1}
$$

227 where n denotes the number of chunks. The middle **228** section of [Figure 3](#page-2-0) illustrates the linear increase of **229** memory size.

 Adaptive Function By visualizing the memory 231 231 distribution across layers 3 , we observed signifi- cant differences in memory usage between high and low layers. Consequently, we propose Adap- tive Function to allocate appropriate memory sizes for different layers. We record the memory reten- tion ratio (the proportion of memory retained after the compression) of various layers. Suppose the memory of the j-th layer at the *i*-th step is \mathbb{M}_i^j 238 memory of the *j*-th layer at the *i*-th step is \mathbb{M}_i^j , the memory retention ratio corresponding to that is defined as:

241
$$
p_i^j = \frac{|\mathbb{M}_{i-1}^j \cap \mathbb{M}_i^j|}{|\mathbb{M}_i^j|}.
$$
 (2)

 Intuitively, the more memory retained from the compression, the larger the memory size should be, and vice versa. Therefore, we can determine the memory size of each layer based on its memory retention ratio. We take the linear function as the basis, and scale it with the normalized memory retention ratio. Suppose that the number of layers is N, the memory size of the linear incremental memory of the j-th layer at the *i*-th step is b_i^j 250 memory of the *j*-th layer at the *i*-th step is b_i^j , then the memory size for adaptive incremental memory **252** is:

$$
m_i^j = \begin{cases} b_0^j & \text{if } i = 0\\ \frac{p_j}{\sum p_j} N b_i^j & \text{if } i > 0 \end{cases}
$$
 (3)

3.3 Decremental Chunk **254**

Although incremental memory (IM) is faster than **255** fixed-size memory, it does not significantly reduce **256** peak GPU memory usage. To address this issue, **257** we propose Decremental Chunk based on Incre- **258** mental Memory (IMDC). IMDC begins with a **259** large chunk size and decreases it as the memory **260** size increases. **261**

Regardless of changes in memory size and chunk **262** size, IMDC maintains a constant average chunk **263** size:

$$
\frac{\sum_{i=0}^{n-1} c_i}{n} = c,\tag{4}
$$

where c_i represents the chunk size at the *i*-th step, *n* 266 is the number of chunks, and c denotes the average 267 chunk size. Since the memory is not involved in the **268** attention computation at the first step, the chunk **269** size of IMDC at the first step is set to the average 270 **chunk size** $(c_0 = c)$. 271

At the *i*-th step, the attention key-value (KV) 272 is the concatenation of the chunk at the i -th step 273 and the memory at the $i - 1$ -th step. Therefore, 274 the length of the attention KV at the i -th step is 275 $c_i + m_{i-1}$. We set the chunk size to ensure that the **276** attention KV length remains constant: **277**

$$
c_i + m_{i-1} = \frac{\sum_{i=1}^{n-1} (c + m_{i-1})}{n-1} \quad (i > 0), \quad (5) \tag{5}
$$

where m_{i-1} is the memory size at the $i - 1$ -th 279 step, and $\frac{\sum_{i=1}^{n-1} (c+m_{i-1})}{n-1}$ is the average length of 280 the attention KV across all steps except the first **281** step. Therefore, the chunk size of IMDC at the i -th 282 step is: **283**

$$
c_i = \begin{cases} c & \text{if } i = 0\\ c + \hat{m} - m_{i-1} & \text{if } i > 0 \end{cases}
$$
 (6)

. **285**

where $\hat{m} = \frac{\sum_{i=0}^{n-2} m_i}{n-1}$

IMDC is illustrated on the bottom section of [Fig-](#page-1-1) **286** [ure 2,](#page-1-1) where the memory size increases while the **287** chunk size decreases. When the memory size is **288** small, the chunk size is large, and vice versa. The **289** incremental memory and decremental chunk strate- **290** gies complement each other, maintaining stable **291** GPU memory usage. The attention KV length of **292 IMDC** remains constant at $c + \hat{m}$ (except for step 293 0), whereas for fixed-size memory it is $c + m_{\text{max}}$. 294 Since the memory size is incremental, we have **295** $m_{\text{max}} > \hat{m}$. Therefore, IMDC consumes less GPU 296 memory than fixed-size memory. **297**

 3 The visualization is shown in [Figure 6](#page-7-0)

Figure 4: TTFT and GPU Memory Usage of LLama2-7B with Fixed-Size Memory (FM) vs. that with our methods (Incremental Memory (IM) and Incremental Memory with Decremetnal Chunk (IMDC)). The setting of sequence length and chunk size followes [Table 3.](#page-11-2) We use different memory sizes for SnapKV and Streaming LLM, because SnapKV requires attention scores which does not support flash attention.

²⁹⁸ 4 Experiments

299 4.1 Experiment Settings

 Iterative Compression We divided the sequence into non-overlapping windows and encode position embedding for memory and chunk at each itera- tion independently instead of reusing the position embedding from the previous steps. Incremental Memory employs the linear increase, with the ini-306 tial memory size defined as $\frac{m_{\text{max}}}{n}$, where m_{max} is the maximum memory size and n is the number of chunks. Unless otherwise specified, the con- figurations of Incremental Memory adhere to this **310** setup.

 KV Cache Compression We tried two prun- ing algorithms: SnaKV [\(Li et al.,](#page-9-1) [2024\)](#page-9-1) and StreamingLLM [\(Xiao et al.,](#page-10-0) [2023\)](#page-10-0). SnaKV fil- ters important key-value pairs based on attention scores, while StreamingLLM selects the most re- cent key-value pairs without relying on attention **317** scores.

 Models We compared our methods with Fixed- Size Memory, abbreviated as FM. Our methods are labeled as IM (Incremental Memory) and IMDC (Incremental Memory with Decremental Chunk). Our experiments were conducted on LLaMA-2- [7](#page-10-4)B [\(Touvron et al.,](#page-9-18) [2023\)](#page-9-18), Tiny-LLaMA [\(Zhang](#page-10-4) [et al.,](#page-10-4) [2024\)](#page-10-4) (1.1B), and InternLM2 [\(Cai et al.,](#page-8-12) [2024\)](#page-8-12) (7B). We used Dynamic NTK [\(bloc97,](#page-8-13) [2023\)](#page-8-13)

to extend the context length of LLama2-7b and **326** Tiny-LLama. We used flash attention [\(Dao et al.,](#page-8-6) **327** [2022\)](#page-8-6) to accelerate the attention calculation. How- **328** ever, SnapKV requires attention scores hence is not **329** compatible with flash attention. **330**

Evaluation We used Collie [\(Lv et al.,](#page-9-19) [2023\)](#page-9-19) to **331** implement our methods and evaluate our methods **332** on LongBench [\(Bai et al.,](#page-8-3) [2023\)](#page-8-3) with OpenCom- **333** pass [\(Contributors,](#page-8-14) [2023\)](#page-8-14). Our Perplexity evalu- **334** ation used the data collected by [Liu et al.](#page-9-7) [\(2020\)](#page-9-7), **335** which are sampled from the Github and Arxiv sub- **336** sets of Redpajama [\(Computer,](#page-8-15) [2023\)](#page-8-15). **337**

4.2 Efficiency Improvement 338

We evaluated the efficiency of our methods (IM 339 and IMDC) on both NVIDIA A800 and NVIDIA **340** RTX 3090 GPUs. The setting of chunk size and **341** sequence length is shown in Appendix [B.1.](#page-11-3) The **342** results are shown in [Figure 4.](#page-4-0) **343**

Time Efficiency We compared the time effi- **344** ciency of our method versus FM in terms of the **345** time to first token (TTFT), the results of which are **346** shown in [Figure 4a.](#page-4-0) We found that our IM and 347 IMDC consistently demonstrates greater efficiency **348** than FM, regardless of the pruners used and the **349** devices employed. Furthermore, the efficiency gap **350** between them widens as the memory size increases. **351** It is because that the larger memory size has a larger **352** impact on the computation time. **353**

 In the A800 experiments, IMDC achieved up to approximately 1.45x (SnapKV) and 1.26x (StreamingLLM) speedup over FM. In the RTX 3090 experiments, the speedup of IM was 1.2x (SnapKV) and 1.08x (StreamingLLM). Increasing the memory size would make the speedup more significant.

 The acceleration of our methods on SnapKV is more significant than that on StreamingLLM. This is because that SnapKV cannot use flash attention, leading to a higher proportion of time spent on at- tention calculation. These empirical results align with our theoretical analysis in Appendix [A.2:](#page-11-4) the acceleration of incremental memory is influenced by two factors—the memory size and the propor- tion of time spent on attention calculation relative to total computation time.

 GPU Memory Efficiency We evaluated the peak memory usage during model prefilling. The results, presented in [Figure 4b,](#page-4-0) indicate that both IM and IMDC consume less GPU memory compared to FM. As the memory size increases, our method saves even more memory compared to the FM.

 In experiments conducted on the A800, the IMDC reduced GPU memory usage by up to 23.3% for SnapKV and 16.2% for StreamingLLM com- pared to FM. Similarly, on the RTX 3090, the reductions were 11% for SnapKV and 8% for StreamingLLM.

 IM also conserves GPU memory usage because the chunk at the i-th step is concatenated with the 385 memory produced at the $i - 1$ -th step for attention. Assuming the iteration involves n chunks (0, 1, ..., $n - 1$), the peak GPU memory is determined by 388 the memory size at the $(n-2)$ -th step rather than the last step. However, the GPU memory reduction achieved by IM is not as significant as that achieved by IMDC, especially in the SnapkV experiment, where the number of chunks is large.

393 4.3 Perplexity Comparison

 We compare the perplexity (PPL) of LLama2-7b when using different types of memory: FM, IM, and IMDC. The test data for perplexity is sampled from Redpajama and encompasses two domains (GitHub and ArXiv). The sequence length and chunk size configurations adhere to the A800 set-tings specified in Appendix [B.1.](#page-11-3)

401 The results shown in [Figure 5](#page-5-0) indicate that **402** there is no significant difference in perplexity be-**403** tween IM/IMDC and FM for either SnapKV or

Figure 5: Perplexity of LLama2-7B with Fixed-Size Memory (FM) versus that with our methods (Incremental Memory (IM) and Incremental Memory with Decremental Chunk (IMDC)).

StreamingLLM. When the memory size is 1024, 404 IM/IMDC even performs slightly better than FM. **405** This may be because IM/IMDC selects KV pairs 406 more concentrated towards the end of the sequence, 407 which is beneficial for lowering PPL. 408

When the chunk size is 1024, a larger memory size results in a lower perplexity. However, **410** when the chunk size is increased to 8192, the trend 411 reverses, with a larger memory size leading to a **412** higher perplexity. This is because 8192 exceeds **413** the model's maximum supported length, and even **414** with Dynamic NTK [\(bloc97,](#page-8-13) [2023\)](#page-8-13), the PPL for 415 Full Attention is high (GitHub PPL: 7.56, Arxiv **416** PPL: 11.09). IM and IMDC consistently achieve 417 lower PPL than FM and Full Attention. This is 418 because the memory length of IM and IMDC in- **419** creases gradually. **420**

When comparing SnapKV and StreamingLLM, **421** we observe that SnapKV achieves significantly **422** lower perplexity than StreamingLLM under identi- **423** cal conditions. **424**

4.4 Benchmark Comparison **425**

We compared the performance of our methods (IM **426** and IMDC) versus FM on LongBench. As shown **427** in [Table 1,](#page-6-0) the performance differences between IM **428** and FM are minimal $\left(\leq 0.5\right)$ under any settings. In 429 most experiments, the performance differences be- **430** tween IM and FM are within 0.15. On InternLM2 **431** and Tiny-LLaMA, IMDC is even better than FM. **432**

Model	Pruner	Memory	Single-Doc QA	Multi-Doc QA		Summarization Few-shot Learning	Synthetic	Code	Avg

Table 1: The performance comparison on LongBench. Full-attn: Full Attention; FM: Fixed-Size Memory; IM: Incremental Memory (ours); IMDC: Incremental Memory with Decremental Chunk (ours). For all models, both the chunk size and memory size are set to 1024.

 This may be because the uneven Chunk Size is more closed to the full attention. An extreme case **is that a sequence of length n is divided into two** 436 chunks with length $n - 1$ and 1.

 Overall, SnapKV performs better than StreamingLLM, especially on LLaMA2-7B. There is no difference in performance between SnapKV and StreamingLLM on Tiny-LLaMA, indicating that the attention scores of smaller models cannot reflect the importance of KV pairs.

 We also found that the average score of Full At- tention on Tiny-LLaMA is only 5.78, even with the Dynamic NTK. This is because the maximum sequence length that Tiny-LLaMA supports is lim- ited to 2048 tokens. In contrast, the average scores of all iterative compression methods (FM, IM, and IMDC) exceed 20, indicating the superiority of it- erative compression over full attention. We further compare the performance and efficiency between it- erative compression and full attention in Appendix **453** [B.3.](#page-12-0)

454 4.5 Optimal Incremental Strategy

 In this experiment, we explored different func- tions to increase memory size and compared their impact on the performance and efficiency of the InternLM2-7b. We used InternLM2-7b for evaluation because the performance gap between IM/IMDC and FM on InternLM2-7b is more sig-

Table 2: Performance comparison of different incremental functions. LINEAR: linear growth; SQRT: fast initial growth that slows down, in the form of $x^{1/2}$; **SQUARE**: slow initial growth that speeds up, in the form of x^2 ; **SQUARE-SQRT**: growth in the form of SQUARE in low layers and SQRT in high layers; ADAPTIVE: set the memory size based on the memory retention ratio in each layer. The specific formulas for the SQRT and SQUARE functions are described in Appendix [A.1,](#page-11-1) and the implementation details of the ADAPTIVE function are provided in Section [3.2.](#page-3-1)We set both Chunk Size and Memory Size to 1024.

nificant than that on LLama-7b. 461

The results are shown in Table [2.](#page-6-1) The outcomes **462** for SnapKV matched our expectations. The SQRT **463** function achieved the best performance, signifi- **464** cantly outperforming the LINEAR function, but **465** it was also the slowest among the five functions. **466** This is reasonable because the memory size of the **467** SQRT function is larger than that of the other func- **468**

Figure 6: The memory distribution across different chunks in various layers for LLaMA2-7b and Internlm2- 7b. The horizontal axis represents the Chunk ID, while the vertical axis represents the Layer ID. The intensity of the color reflects the proportion of memory distribution, with brighter colors indicating a higher proportion of memory within a given chunk. We have excluded the last column, as the majority of memory key-value pairs are concentrated in the final chunk.

 tions. Both SQUARE-SQRT and ADAPTIVE are designed to set the appropriate memory size for dif- ferent layers. They exhibited the same performance as the SQRT function and the same efficiency as the LINEAR function. The SQUARE function was the most efficient among the five functions, but its performance was the worst.

 As for the experiments on StreamingLLM, the impact of incremental functions was minimal. LIN- EAR and ADAPTIVE functions achieved the best performance. Overall, considering both perfor- mance and efficiency, the ADAPTIVE function is the optimal incremental function.

482 4.6 Analysis

 Visualization of Memory Map We conducted a statistical analysis of the memory distribution across chunks by recording the chunk ID of each key-value pair in the memory. The data for this evaluation is the same as that used for the PPL Comparison (Section [4.3\)](#page-5-1). For this analysis, we utilized fixed-size memory instead of incremen- tal memory. The results, illustrated in [Figure 1,](#page-0-0) indicate that the majority of the memory is con- centrated in the last few chunks, irrespective of the models or pruners used.

 We further investigated memory distribution across different layers for both LLaMA2-7b and InternLM2-7b. The results are shown in [Figure 6.](#page-7-0) We found significant variation in memory distribu- tion across different layers of LLaMA2-7b, with higher layers exhibiting a more uniform distribu- tion than lower layers. Conversely, for InternLM2- 7b, the differences in memory distribution across layers are minimal. Inspired by this observation,

Figure 7: The variation of the Memory Retention Ratio during the iteration. The Memory Retention Ratio is defined as the proportion of memory retained after compression, see [Equation 2.](#page-3-3) The higher Memory Retention Ratio indicates the less memory being forgotten after compression. The pruner used is SnapKV.

we propose adaptive Incremental Memory in Sec- **503** tion [3.2.](#page-3-1) **504**

Incremental Long-Term Memory The test data **505** was sampled from the Github and Arxiv subsets **506** of RedPajama, with each sample containing 32k **507** tokens. During the iteration, the memory is con- **508** tinuously updating. We visualized the memory **509** retention ratio defined in [Equation 2](#page-3-3) in [Figure 7.](#page-7-1) **510**

We observed that the memory retention ratio for 511 LLaMA2-7b and Tiny-LLaMA increases linearly **512** with iterations, whereas the memory retention rate 513 for Internlm2-7b exhibits fluctuations. The increas- **514** ing memory retention ratio suggests that as the **515** model undergoes more iterations, it tends to retain **516** more long-term memory. 517

5 Conclusion **⁵¹⁸**

In this paper, we addressed the inefficiencies in **519** long-context prefilling of LLM by introducing two **520** novel techniques: Incremental Memory and Decre- **521** mental Chunk. Incremental Memory optimizes **522** memory usage by dynamically increasing the mem- **523** ory size during prefilling, avoiding unnecessary **524** computational overhead. Decremental Chunk com- **525** plements this approach by dynamically adjusting **526** the chunk size, maintaining stable and lower GPU **527** memory usage. Our experimental results show that **528** the combination of these methods significantly im- **529** proves efficiency, with less prefilling times and **530** GPU memory consumption compared to traditional **531** fixed-size memory approaches. **532**

⁵³³ Limitations

- **534** 1. In our experiments, we tested the performance **535** and efficiency of our methods using sequences **536** with length of 32k tokens. However, iterative **537** compression can support inputs of unlimited **538** length. We have not yet validated the effec-**539** tiveness of our method on longer sequences, **540** such as those with one million tokens.
- **541** 2. We have evaluated our methods on LLama2- **542** 7b, InternLM2-7b, and Tiny-LLama. How-**543** ever, due to limitations in computational re-**544** sources, we have not tested our model on the **545** larger models, such as LLama2-70b. Never-**546** theless, we believe our method is more suit-**547** able for larger models because the memory **548** bottleneck is more pronounced in these cases.

⁷⁹⁵ A Supplementary Method Details

796 A.1 Alternative Incremental Functions

797 We present several alternatives to the linear func-**798** tion for increasing memory size, namely the SQRT **799** and the SQUARE:

$$
m_i^{\text{square}} = \frac{(m_{\text{max}} - m_0)i^2}{(n-1)^2} + m_0 \tag{7}
$$

801
$$
m_i^{\text{sqrt}} = \frac{(m_{\text{max}} - m_0)\sqrt{i}}{\sqrt{n-1}} + m_0 \tag{8}
$$

 The growth rate of the SQRT is initially slow but accelerates over time, whereas the SQUARE func- tion exhibits the opposite behavior. The memory size of the SQUARE function is smaller than that of the LINEAR, which in turn is smaller than that of the SQRT function.

 Based on the memory distribution visualization in Section [4.6,](#page-7-2) we observed that the memory distri- bution in the higher layers of LLaMA2-7b is more uniform compared to the lower layers. Therefore, we propose a new increase function, SQUARE- SQRT, which combines the SQUARE and SQRT function: using SQUARE function for the lower layers, and SQRT function for the higher layers.

816 The integral of the sum of SQUARE and SQRT **function** $(m_i^{\text{high}} + m_i^{\text{low}})$ over the interval $[0, n-1]$ 818 equals $n(m_{\text{max}} + m_0)/2$, which is the same as that of linear function. Therefore, theoretically, the **computational cost of SQUARE-SQRT is equiva-**lent to that of LINEAR.

822 A.2 Time Complexity Analysis

 The acceleration of IM over fixed-size Memory is determined by two factors: 1) the relative sizes of the memory size and chunk size; 2) the proportion of the total computation time occupied by the atten- tion calculation. Assuming the maximum memory size is m_{max} , the memory size at the *i* step is m_i , 829 the chunk size is c, the number of chunks is n , then the acceleration of IM over fixed-size Memory is given by:

$$
r\left(\frac{m_{\max}+c}{\hat{m}+c}-1\right)+1,\tag{9}
$$

833 where $\hat{m} = \frac{\sum_{i=0}^{n-2} m_i}{n-1}$. Therefore, when $m_{\text{max}} \gg c$ 834 **and r** is close to 1, incremental memory achieves 835 **an ideal acceleration ratio:** $\frac{m_{\text{max}}}{\hat{m}}$.

Table 3: Setting of Chunk Sizes and Sequence Lengths for Different Devices and Pruners

IM reduces the time complexity of the attention **836** calculation from $O(ms + s^2)$ to $O(f(m, s) + s^2)$ where f depends on the specific incremental func- 838 tion. If f is a power function, the time complexity **839** is $O(ms)$. If f is a reciprocal function, the time 840 complexity is $O(\log(s)m + s^2)$). **841**

B Supplementary Experiments **⁸⁴²**

B.1 Experiment Setting of Chunk size and **843 Sequence Length** 844

Since the GPU memory of A800 is much larger 845 than that of RTX 3090, we set a larger sequence **846** length and chunk size for the experiment on A800. **847** Furthermore, SnapKV does not support flash atten- **848** tion, hence the chunk size and sequence of which **849** is larger than that of StreamingLLM. We report the **850** detail setting in [Table 3.](#page-11-2) Both the experiments of **851** Efficiency Comparison [\(4.2\)](#page-4-1) and PPL Comparison **852** [\(4.3\)](#page-5-1) follow this setting. **853**

B.2 Incremental Fixed Memory Versus 854 Incremental Dynamic Incremental **855**

AutoCompressors [\(Liu et al.,](#page-9-7) [2020\)](#page-9-7) also dynami- **856** cally increases the memory size while iterating over **857** chunks. Although their memory size grows incre- **858** mentally, they do not compress the existing mem- **859** ory; instead, they append the compressed chunks to **860** the existing memory. In other words, their memory **861** consists entirely of long-term memory that is nei- **862** ther updated nor forgotten. Conversely, our method **863** updates the memory content through compression **864** at each step. **865**

Which kind of incremental memory is better? 866 We compared the performance of them by evalu-
867 ating the perplexity of LLaMA2-7b. The exper- **868** imental setup is consistent with that in Section **869** [subsection 4.3,](#page-5-1) and the results are shown in Fig- 870 [u](#page-9-7)re [Figure 8.](#page-12-1) We refer to AutoCompressors [\(Liu](#page-9-7) **871** [et al.,](#page-9-7) [2020\)](#page-9-7) as Incremental Fixed Memory, and our **872** method as Incremental Dynamci Memory. **873**

According to [Figure 8,](#page-12-1) the perplexity of Dy- **874** namic Incremental Memory is significantly lower **875**

), **837**

Figure 8: Incremental Fixed Memory [\(Liu et al.,](#page-9-7) [2020\)](#page-9-7) versus Incremental Dynamic Memory (ours). The data for evaluation is the same as that used in PPL Comparison (Section [4.3\)](#page-5-1). Both approaches increase memory size linearly during iterative compression. For both methods, the chunk size and the maximum memory size are set to 1024.

Table 4: The maximum input length supported by Full Attention and Interative Compression on A100 and RTX 3090 was evaluated. "Save Logits" refers to whether the model's output logits should be saved. We use IM for iterative compression which utilizes the StreamingLLM Pruner, both the chunk size and memory size of which are set to 1024.

 than that of Fixed Incremental Memory in almost all configurations, which demonstrates the supe- riority of our method and suggests that memory needs to be updated, i.e., long-term memory alone is insufficient.

881 B.3 Why Iterative Compression?

 To verify the advantages of iterative compression over Full Attention, we compared the maximum sequence length that iterative compression and Full Attention support at the prefilling stage. we set the memory size and chunk size to 1024 for IMDC and use the StreamingLLM pruner as the compresser.

888 The results are shown in the [Table 4.](#page-12-2) Whether **889** on the A800 or 3090, the maximum sequence

Method	Memory Size	Single-Doc QA	Time (seconds)
	1024	22.36	3181.7
	2048	27.34	3187.2
Iterative Compression	4096	34.88	3693.2
	8192	39.16	3802.9
Full Attention	NA	40.93	12101.4

Table 5: The performance and inference time of Full Attention Versus Iterative Compression with different memory sizes evaluated on a subset of LongBench (Single-Document QA). We use IM for iterative compression and LLama2-7b for the test model.

length supported by iterative compression is far **890** greater than that supported by Full Attention (4 **891** times greater). If we do not save model's logits, **892** or only save the logits of the last chunk, iterative **893** compression can support infinite sequence lengths. **894**

In [Table 1,](#page-6-0) the performance of InternLM2-7B **895** with full attention is much better than iteractive 896 compression (FM, IM, IMDC), particularly in QA **897** tasks. We hypothesize that the small memory size **898** is the primary cause of this discrepancy. Conse- **899** quently, we conducted a comparative study of it- **900** erative compression and Full Attention with an **901** increased Memory Size. **902**

The results are shown in [Table 5,](#page-12-3) where we can **903** observe that increasing memory size is beneficial **904** to narrow the gap between iterative compression **905** and full attention. If the memory size is set to **906** 8192, the performance of iterative compression on **907** Single-Document QA is comparable with that of **908** full attention, while requiring only 31% inference **909 time.** 910
