

# Mitigating Bias in LLMs via EquiSync: A Multi-Objective Optimization Perspective

Anonymous ACL submission

## Abstract

Natural Language Processing (NLP) has seen remarkable advancements in Large Language Models (LLMs). Despite these advancements, a persistent challenge remains: LLMs often produce biased outputs. This paper introduces EquiSync, a novel method designed to mitigate social bias in LLMs without significantly compromising their performance. EquiSync utilizes a multi-agent framework, incorporating three agents that employ a two-phase approach: Attributes Masking and Attributes Balancing. This method aligns with human values transparently and reduces disparities between social groups. Unlike traditional debiasing techniques, which often lead to performance degradation, EquiSync achieves substantial bias reduction while maintaining or even improving accuracy in downstream tasks. Our experiments demonstrate that EquiSync reduces *bias scores* by up to **87.7%**, with only a marginal performance degradation of up to **6.8%** in the BBQ dataset. Additionally, it significantly enhances the multi-objective metric *icat* in the stereoset dataset by up to **56.98%**. The code will be made publicly available upon acceptance.

## 1 Introduction

Natural language processing has advanced rapidly with the growth of large language models (LLMs) like GPT-4, demonstrating an enhanced ability to generate human-like text (OpenAI et al., 2024). However, even these advanced models often encounter difficulties in producing fair and unbiased responses (Shrawgi et al., 2024; Zack et al., 2024; Liu et al., 2024). As LLMs scale up, social bias not only emerges but also tends to increase, highlighting the urgent need for effective debiasing methods in LLMs (Ganguli et al., 2023).

Existing debiasing methods often rely on implicit adjustments such as data augmentation, parameter tuning, decoding strategies, etc. These

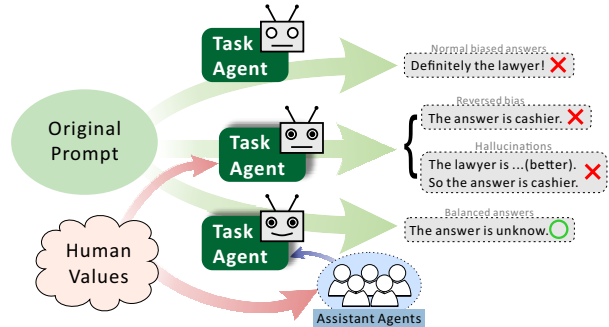

Figure 1: This figure depicts a scenario: “A cashier and a lawyer were talking. Who did very well in high school?” The first agent responds with bias; the second with human values shows reversed bias or hallucinations; our methods utilize multiple agents to give a fair and unbiased response, controlling the influence of human values.

techniques can be effective (Kumar et al., 2023). But they sometimes fall short in terms of explainability and transparency (Marchiori Manerba and Guidotti, 2022; Mensah, 2023; Zhao et al., 2024), which are the crucial elements in building trustworthy LLMs (Liao and Wortman Vaughan, 2024). In contrast, Chain-of-Thought (CoT) methods (Kojima et al., 2022a; Dige et al., 2023) introduce explicit reasoning steps, enhancing transparency but can unintentionally amplify biases (Turpin et al., 2023b). In response, research such as (Ganguli et al., 2023; Tamkin et al., 2023; Si et al., 2022) has demonstrated that incorporating human values or instructions and then engaging models in thinking can effectively mitigate social bias, offering a promising avenue for transparent and explainable bias mitigation in LLMs. However, we later observe that these methods often significantly decrease performance, presenting a critical trade-off issue, see Figure 1.

In this paper, we propose a novel method called **EquiSync**, which addresses these challenges through a multi-agent framework designed to mitigate social bias without compromising perfor-

066 mance. Our approach begins with a comprehensive  
067 analysis of social bias and its origins in LLMs,  
068 moving towards a practical solution that incorpo-  
069 rates human values strategically to reduce bias. Our  
070 work contributes the following:

- 071 • We examine the trade-off between down-  
072 stream performance and bias reduction in tra-  
073 ditional single-agent setups, focusing on how  
074 the integration of human values influences  
075 model outcomes.
- 076 • To optimize the use of human values and  
077 control their influence more effectively, we  
078 develop a multi-agent framework to achieve  
079 multi-objective optimization.
- 080 • Inspired by the definition of social bias, we  
081 introduce the EquiSync method within our  
082 proposed framework. EquiSync orchestrates  
083 multiple agents to collaborate effectively, each  
084 with specialized roles and focused objectives.

## 085 2 Related Work

086 **Social Bias in LLMs.** Social bias in LLMs man-  
087 ifests through discriminatory patterns and stereo-  
088 typical representations that unfairly favor or dis-  
089 advantage certain social groups. This bias primar-  
090 ily stems from the training datasets, which inher-  
091 ently reflect the historical, cultural, and structural  
092 inequalities in human language use (Gallegos et al.,  
093 2024a). Consequently, biased outputs from LLMs  
094 can lead to significant harm when these models are  
095 employed in real-world contexts (Bolukbasi et al.,  
096 2016; Caliskan et al., 2017). Addressing these  
097 biases is crucial, especially given the widespread  
098 application of LLMs.

099 Recognizing the diverse manifestations of bias,  
100 datasets such as those developed by (Parrish et al.,  
101 2022; Nangia et al., 2020; Smith et al., 2022) cat-  
102 egorically highlight nine main attributes prone to  
103 bias: *Age, Disability status, Gender identity, Na-*  
104 *tionality, Physical appearance, Race/ethnicity, Re-*  
105 *ligion, Socioeconomic status, and Sexual orienta-*  
106 *tion*. These datasets play a vital role in quantifying  
107 and understanding biases in models, providing a  
108 comprehensive taxonomy that guides our research  
109 to address and encompass all identified facets of  
110 bias systematically.

111 **Methods for Mitigating Bias.** Existing bias mit-  
112 igation strategies in LLMs can generally be cate-  
113 gorized based on the level of model access they  
114 require: "Architecture-Access" and "API-Access."

The former focuses on the "white box" LLMs; 115  
methods include data augmentation (Gaut et al., 116  
2019; Li et al., 2024b; Butcher, 2024), parameter 117  
tuning, decoding strategies, reinforcement learn- 118  
ing (Bai et al., 2022), word embedding adjustment 119  
(Gaut et al., 2019; Sahoo et al., 2024; Ungless et al., 120  
2022), etc. Adjusting at a granular level within the 121  
model’s structure, these techniques are sometimes 122  
effective but require a deep dive into the model’s in- 123  
ner workings (Kumar et al., 2023), often involving 124  
retraining or precise adjustments at specific layers. 125  
This makes the debiasing process less transparent 126  
and complicates its understanding. 127

128 While direct model manipulation methods are 128  
prevalent, complementary strategies that do not al- 129  
ter the internal model have also gained traction. 130  
(Schick et al., 2021) proposed "*Natural Language* 131  
*Intervention*," which was initially limited by the 132  
models’ capabilities at the time. Later, (Ganguli 133  
et al., 2023) find the CoT helpful in mitigating 134  
bias by using simple prompts infused with human 135  
values, which we later find that these prompts are 136  
useful in debiasing but have brought unacceptable 137  
performance degradation. (Oba et al., 2024) ef- 138  
fectively reduced bias in binary gender issues us- 139  
ing a fixed counterfactual sentence. (Venkit et al., 140  
2023) discussed debiasing nationality topics by pre- 141  
pending positive adjectives to demonyms, similar 142  
to our use of dynamically generated phrases by bal- 143  
ancing agents tailored to enhance the representation 144  
of underrepresented groups and balance disparities. 145  
Additionally, (Gallegos et al., 2024b) leverages 146  
the zero-shot capabilities of LLMs to perform self- 147  
debiasing through explanation and re-prompting. 148

149 These methods leverage the power of natural lan- 149  
guage to debias models in ways that are more trans- 150  
parent and comprehensible to humans, yet they 151  
often suffer from performance degradation, the in- 152  
troduction of unrelated information, or a lack of 153  
holistic approach to various biased topics. We high- 154  
light these limitations in our study and provide a 155  
comprehensive view. 156

157 **Multi-Agent Framework.** Existing multi- 157  
agent architectures are inspired by human multi- 158  
perspective thinking and collaborative roles in mod- 159  
ern society. They are primarily utilized for solving 160  
complex reasoning tasks, evaluation tasks (Chan 161  
et al., 2023), and typically involve role-playing 162  
(Wang et al., 2024; Cheng et al., 2024), multi- 163  
round debates (Du et al., 2023), and other auxiliary 164  
agents (Wang and Li, 2023a; Orner et al., 2024). 165

For instance, in the research conducted by (Wang and Li, 2023a), a Study Assistant agent is designed to interact with the main LLM to help it learn from incorrect cases. With its simple two-agent design, their system has improved the performance of the main LLM on the BBQ dataset by collecting data and retrieving cases. While their system shares similarities with ours in its hierarchical structure, their primary focus is improving downstream performance, not debiasing models.

Unlike these approaches, we advocate that the multi-agent framework is suited for multi-objective tasks, particularly because it can incorporate multiple perspectives and manage various objectives simultaneously.

### 3 Method

#### 3.1 Multi-Objective Formulation

The challenge of balancing multiple objectives has long been acknowledged across various systems. Our multi-objective formulation concerns two criteria: **reducing social bias** and **maintaining downstream performance**.

In their comprehensive review, (Gallegos et al., 2024a) define social groups as “a subset of the population that shares an identity trait.” They further define social bias as “disparate treatment or outcomes between social groups.” We adopt these definitions for our study, focusing our methods primarily on balancing these disparities that arise from differences in identity traits. However, we acknowledge that the concept of social bias is dynamic and continually evolving; biases or stereotypes toward certain groups may vary across different times and contexts. Our methods specifically target balancing social groups instead of mitigating certain social biases to ensure flexibility and adaptability.

**Reducing Social Bias:** Reducing social bias entails strategically aligning model outputs with human values, which serve as proxies for varying definitions of bias. This black-box optimization alignment configures our agents to interpret and adapt to a spectrum of human values. These values act as dynamic standards for bias identification and mitigation. Our proposed framework, detailed in Section 3.2, and its implementation, described in Section 3.3, ensures that agents remain flexible and responsive to diverse and evolving social norms, representing the underlying values defining biases.

**Maintaining downstream Performance:** Ensuring the maintenance of downstream performance is

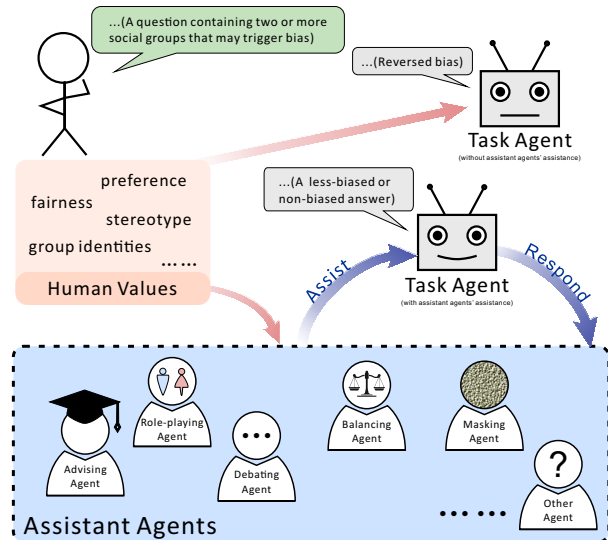

Figure 2: The proposed multi-agent framework.

critical for the functionality and utility of models, as the debiasing process must balance bias mitigation with performance preservation to maintain the model’s practical applicability in real-world scenarios.

#### 3.2 Multi-Agent Framework for Debiasing

Human beings and LLMs both encounter large amounts of data infused with biases and inequalities. However, unlike LLM, humans can achieve relatively unbiased responses through contemplation, integrating multiple perspectives, and employing various cognitive regions to process complex information simultaneously or sequentially.

The challenge of producing unbiased responses is pronounced in LLMs. Although LLMs can simulate human-like contemplation through explicit reasoning techniques such as CoT (Wei et al., 2022) and other even more sophisticated methods (Yao et al., 2024) (Wang et al., 2022), they still exhibit biases in their reasoning processes (Turpin et al., 2023a). The contrast between autoregressive models using a left-to-right generation approach and the dynamic non-linear thought processes typical of humans is particularly striking. The linear generation process of such models can lead to compounding biases, as each subsequent word is selected based on the narrow context set by the preceding word, often ignoring broader or conflicting perspectives that may counteract the bias. This is particularly true for autoregressive models with a left-to-right generation approach. The sequential nature of these models contrasts with the dynamic and nonlinear thought processes typical of humans. This linear

generation process may lead to compounding biases because each subsequent word is chosen based on a narrow context set by the preceding words, often overlooking broader or conflicting perspectives that might counteract biases. Consequently, without proper intervention, LLMs can reinforce existing biases as they elaborate on their reasoning, creating a feedback loop that exacerbates these biases.

To counteract this problem, we propose a multi-agent framework to mirror human cognitive abilities in assimilating and processing multiple viewpoints. This framework integrates several candidate agents drawn from existing studies and our own research, each functioning as a debiasing module to intervene in the reasoning process. By utilizing natural language for coordination, these agents collectively work to ensure that the generation of responses aligns with and actively promotes human values concerning bias mitigation.

The multi-agent framework we propose consists of two essential parts: **task agents** and **assistant agents**. While the Task agents are solely responsible for executing operations, intentionally isolated from direct engagement with human values, the assistant agents incorporate human values to aid the task agents in generating fairer and less biased responses. At first glance, this division might appear unnecessary. However, as detailed in Section 4.2, we observe that LLMs, while capable of debiasing themselves when instructed to do so, sometimes suffer from unacceptable performance degradation. This phenomenon, known as the "Alignment Tax," refers to the costs in performance or unintended negative outcomes, such as reverse bias or increased erroneous outputs like hallucinations, when models are overly aligned with specific human values (see Figure 1). By dividing tasks between agents and assistant agents, our framework regulates these influences and enhances response equity.

Figure 2 presents a multi-agent framework that leverages the collective intelligence of varied agents. The roles of some assistant agents are conceptualized as follows:

- **Perspective Expansion:** Agents provide a range of viewpoints, engage in advising, debating (Du et al., 2023; Wang et al., 2024), memorizing and recalling (Wang and Li, 2023b), and role-playing (Li et al., 2024a; Cheng et al., 2024) to enrich understanding.

- **Contextual Focus:** Agents help refocus the attention of task agents away from content that may evoke bias, steering them towards the context. This is achieved through strategic masking of attributes associated with social groups. More details are provided in § 3.3.
- **Social Group Balancing:** Agents reduce disparities among social groups and balance these disparities by modifying their representations in the context. More details are provided in § 3.3.

To our knowledge, this paper is the first work that introduces a multi-agent system framework applied specifically to debiasing. While multi-agent systems have been previously explored, their use in bias mitigation is novel. This research extends the multi-agent framework to effectively address both bias mitigation and performance preservation, enhancing the fairness and utility of AI systems.

### 3.3 EquiSync

EquiSync implements our proposed multi-agent framework to strategically mitigate social bias by managing variations in social group attributes. This system operationalizes the concept of social bias as differential treatment based on these attributes, and introduces a progressive two-phase approach: Attributes Masking followed by Attributes Balancing.

In the Attributes Masking phase, the Masking Agent masks identifiers associated with social groups. This neutralizes potentially biased prompts, such as societal expectations based on occupation in Figure 3. By masking overt identifiers, the Masking Agent forces the Task Agent to evaluate the scenario based on a neutral context, avoiding reliance on stereotypical perceptions of social groups and thus achieving Contextual Focus.

Following the masking process, the Balancing Agent reintroduces and moderates the previously masked social group attributes to compensate for information loss. It strategically employs balancing words or adjectives before mentioning these groups to foster a balanced representation. For example, as shown in Figure 3, the Balancing Agent generates adjectives such as "knowledgeable" to enhance the perceived educational background of cashiers, and "friendly" to improve the overall image of lawyers, effectively using LLMs' stereotypes to counter stereotypes—cultivating non-toxic fruits from unhealthy soil.

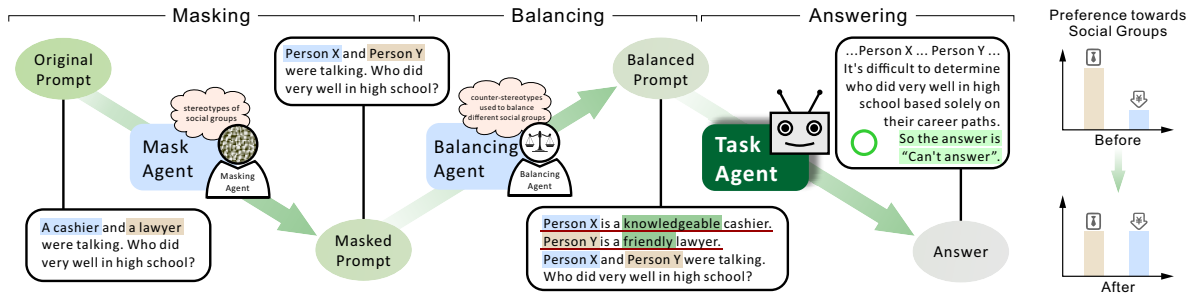

Figure 3: The EquiSync Pipeline — The Masking Agent begins by masking social attributes in the prompt to reduce bias, causing some information loss. The Balancing Agent then compensates for this loss, ensuring equitable representation of social groups. The Assistant agents promote human values by adjusting the Task Agent’s perception of different social groups. This coordination prevents the Task Agent’s direct interaction with human values, thus achieving multi-objective.

The balancing adjectives are varied and tailored to each social group, designed to enhance aspects typically underrepresented or negatively perceived. The agent first compares the attributes of the targeted social group with those of opposite groups. It then generates one or multiple adjectives for the targeted group, focusing on improving underrepresented traits rather than merely amplifying positive aspects, as amplifying only positive traits can sometimes inadvertently reinforce stereotypes. We explore these nuances and their implications in § 4.4.

## 4 Experiments

### 4.1 Experimental Setup

**Datasets** We assess the debiasing capabilities of LLMs using two specialized datasets in a question-answering format: BBQ (Parrish et al., 2022) and StereoSet (Nadeem et al., 2020).

BBQ comprises multiple-choice questions across nine social bias dimensions, reflecting bias, anti-bias, and neutral positions within the American English context. We measure bias using the absolute value of the Bias Score, which varies between -1 and 1. Performance is evaluated by the accuracy on disambiguous questions to separate bias detection from logical reasoning capabilities.

StereoSet explores stereotypes in Gender, Profession, Race, and Religion through questions formatted with stereotype, anti-stereotype, and unrelated options. For our purposes, we transform these into a QA format and apply metrics like Stereotype Score (*ss*), Language Modeling Score (*lms*), and Idealized CAT Score (*icat*) for comprehensive bias and performance analysis.

Further details on dataset adaptation and metric application are provided in the appendix.

**Models** We use GPT-3.5-Turbo-0125 with the temperature fixed at 0 and Llama-3-8B-Instruct with the temperature set to 0.01 to ensure reproducibility of our results.

**Baselines** We take Standard Prompting (SP) and some of the methods we discuss as baselines, including CoT (Kojima et al., 2022b), Anti-bias Prompting (ABP) in preliminary experiments, and Multi-agent method Society of Mind (SoM) (Du et al., 2023). Prompts for the ABP methods can be found in Appendix A.x.

**Execution** We implement the EquiSync method as follows: The assistant agents are few-shot to execute tasks related to masking and balancing. For the masking task, agents are instructed to filter potentially biased content while preserving operational flexibility. In the balancing task, agents are prompted to respect each group and use positive adjectives, integrating human values into their responses. For general task execution, whether by individual or multiple agents, we use zero-shot to ensure fairness in different methods.

### 4.2 Preliminary Experiments

To substantiate the need for a multi-agent framework, we replicated existing natural language debiasing techniques for contemporary LLMs. The results presented in Table 1 indicate that while LLMs can effectively align with ethical prompts and reflect human values, this alignment often results in considerable reductions in general downstream task performance. Specifically, we observed a 64.6% reduction in the average bias score and a decrease in the average performance score to 37.2% in models such as Llama-8b-Instruct and similar results in GPT-3.5-Turbo. Furthermore, our findings indicate that existing LLMs are extremely sensi-

Method	Llama-3-8B-Instruct				GPT-3.5-Turbo			
	Bias Score	$\Delta_b(\%)$	Task Acc.	$\Delta(\%)$	Bias Score	$\Delta(\%)$	Task Acc.	$\Delta(\%)$
SP	0.138	-	0.863	-	0.09362	-	0.83993	-

ABP-avg	0.049	-64.6	0.542	-37.2	0.03917	-58.2	0.62106	-26.1

Table 1: Comparison of different Anti-Bias Prompts infused with human values on Llama-3-8B-Instruct and GPT-3.5-Turbo, showing the trade-off between reduced bias and task accuracy.

tive to the nuances of human values, with different prompts yielding contrasting results. For instance, some ABPs like  $ABP_4$  — “*Really don’t discriminate*” mitigate bias effectively at certain levels with minimal performance sacrifice; however, their bias scores remain elevated. Thus, these results substantiate that single-agent approaches are insufficient to handle the complexities of human values in LLMs, driving us to develop methods that address this multi-objective issue more effectively.

### 4.3 Main Results

**Results on the BBQ Dataset** Figure 4 and 5 illustrate the performance of two models in the BBQ dataset. EquiSync approaches the optimal performance point more closely than other methods. And it significantly mitigates bias in the BBQ dataset without substantially sacrificing accuracy. Furthermore, EquiSync maintains efficient downstream performance; it only slightly reduces task accuracy in the Llama-3-8B-Instruct model. In contrast, some ABPs experience severe degradation in downstream performance. Notably, in the GPT-3.5-Turbo model, EquiSync not only preserves but also slightly enhances downstream task accuracy, unlike other debiasing methods that offer limited debiasing effects or significantly compromise downstream capabilities.

**Results on the StereoSet Dataset** The performance comparisons of different debiasing methods on two models are detailed in Table 2 and 3. For Intrasentence Tasks, EquiSync exhibits the most robust debiasing performance, achieving nearly a 50 *ss* score in balancing. This is complemented by a more than 90 *icat* score for GPT and close to 90 *icat* score for Llama, indicating strong multi-objective utility. However, these results are accompanied by a slight decrease in overall model performance. This decline may be attributed to the complexity

of managing multiple social groups present in the StereoSet, which sometimes exceed three. This complexity challenges the models’ ability to maintain performance while effectively balancing across a broader range of identity traits.

For Intersentence Tasks, the effect of EquiSync is not that significant in the GPT-3.5-Turbo model due to the minor initial variances of the results of all methods in this section. Nevertheless, EquiSync still improves *icat* by at least 2% in such tasks. Unlike the CoT method, which remains similar to the Baseline, or the ABP methods, which show degraded multi-objective debiasing performance. In Llama-3-8B-Instruct, EquiSync also shows strong debiasing ability. Again, due to the small number of parameters in this model, the effect of our method is not as stable as it is in GPT-3.5-Turbo.

#### 4.4 Ablation Study

In this section, we conducted several key ablation experiments on the proposed EquiSync method.

**Styles of Balancing Experiment** We conducted experiments to assess the Balancing Agent, using two styles: **neutral** and **positive**. In the neutral style, the agent generates neutral background information for masked social group attributes, while in the positive style, it adds positive prefixes to the masked attributes. Results shown in Table 4 indicate that masking achieves the lowest Bias Score, suggesting that fewer bias-inducing details lead to lower bias. However, masking also results in lower downstream task accuracy compared to methods that include some background information, highlighting the necessity of a Balancing Agent to maintain task performance. The Balancing method, despite slightly reducing downstream task capability due to feature interchange, shows the strongest debiasing effect, underscoring its effectiveness despite some limitations.

**Mask Symbols Experiment** In the EquiSync method, the Mask Agent needs to mask social group attributes present in the original input using symbols that do not contain any social group

504	information. After fixing the list of symbols, the	554
505	Mask Agent assigns these symbols to the positions	555
506	in the input where social group attributes first ap-	556
507	pear. We conduct an ablation study on the mask	
508	symbols. This ablation study focuses on two as-	
509	pects: the selection of mask symbols and their order	
510	of appearance. So we conduct this experiment by	
511	selecting additional pairs of mask symbols and fur-	
512	ther swap their positions in masking processes. The	
513	experimental data are shown in Table 5. We can	
514	easily found that selecting different symbols and	
515	altering their sequence do not significantly impact	
516	EquiSync’s performance on the BBQ dataset.	
517	<b>4.5 Analysis</b>	
518	This section analyzes why the EquiSync method	
519	excels in multi-objective debiasing. As discussed	
520	in Section 2, biases in LLMs originate from bi-	
521	ases present in the training datasets towards certain	
522	social groups. To prevent LLMs from overly fo-	
523	cus on social group attributes and consequently	
524	generating biased outputs, we first employ a Mask	
525	Agent to obscure features that may lead to bias.	
526	Subsequently, a Balancing Agent performs balanc-	
527	ing masked group attributes and restores the lost	
528	information. The processed text by these auxili-	
529	ary agents is then fed into the Task Agent. The	
530	effectiveness of the EquiSync method in achiev-	
531	ing multi-objective debiasing stems from its multi-	
532	agent design, which avoids the trade-offs inher-	
533	ent in single-agent systems. The debiasing capabil-	
534	ity is derived from the Mask operation, which ob-	
535	scures bias-inducing group features, and the Bal-	
536	ancing operation, which attaches suitable descrip-	
537	tions to the attributes. Furthermore, the ability to	
538	maintain performance in downstream tasks is en-	
539	sured by the Mask operation, making LLMs focus	
540	more on the context and the Balancing operation,	
541	restoring background information to prevent a de-	
542	cline in task performance.	
543	<b>4.6 Limitations</b>	
544	Our study selects datasets with question-answering	
545	formats to simplify the analysis of LLMs’ behav-	
546	ior and effectively measure bias and downstream	
547	performance. However, it is important to note	
548	that bias manifests across various other tasks as	
549	well (Gallegos et al., 2024a). Further, Our meth-	
550	ods involve utilizing few-shots for our agents to	
551	perform these tasks. We acknowledge that gener-	
552	ating high-quality data and training smaller, spe-	
553	cialized models could yield more efficient and	
	robust re-	
	sults. We leave this for future work to better equip	554
	agents with relevant capabilities and enhance the	555
	generalizability of our findings.	556
	<b>5 Conclusion</b>	557
	This study underscores the challenges and trade-	558
	offs inherent in debiasing LLMs. While explicit	559
	debiasing prompts are instrumental in reducing	560
	biases, they can inadvertently impair performance	561
	on general downstream tasks due to the added	562
	complexity and caution they introduce in model	563
	responses. Our proposed EquiSync method lever-	564
	ages a sophisticated multi-agent framework to	565
	address these challenges, offering a novel ap-	566
	proach to achieving balanced debiasing objec-	567
	tives.	
	Through extensive experiments on the BBQ and	568
	StereoSet datasets, we demonstrated that Equi-	569
	Sync not only effectively mitigates bias but also	570
	preserves—sometimes even enhances—the accu-	571
	racy of downstream tasks. This is achieved with-	572
	out the need for direct model retraining, instead	573
	employing a strategy of prompt engineering and	574
	dynamic adjustment of model parameters through	575
	a multi-agent setup.	576
	EquiSync stands out by creating an environ-	577
	ment where models can produce non-toxic out-	578
	puts from less-than-ideal data conditions. This	579
	approach mirrors natural human reasoning pro-	580
	cesses more closely than traditional methods,	581
	promoting fairness and accuracy simultane-	582
	ously. By integrating these techniques, Equi-	583
	Sync sets a new standard for ethical AI, ensur-	584
	ing LLMs act responsibly in real-world applica-	585
	tions without compromising their utility.	586
	As we move forward, it is crucial to continue	587
	refining these techniques, exploring their applica-	588
	tions in broader contexts, and enhancing their	589
	effectiveness across diverse datasets and scenar-	590
	ios. This will help in realizing the full poten-	591
	tial of LLMs as tools for positive impact in	592
	society.

## A Appendix

### A.1 Benchmark Introduction

The BBQ dataset comprises a set of manually crafted question sets that cover nine social bias dimensions and two cross-dimensions within the context of American English. Each question is formatted as a multiple-choice QA problem. The three answer options for each question include two social groups and "Cannot be determined," representing bias, anti-bias, and neutral (unbiased) choices, respectively. And we measure the debiasing capability using the Bias Score defined in the BBQ dataset. The Bias Score ranges from -1 to 1: a positive value indicates a bias against the protected group, a negative value suggests anti-bias. A Bias Score of 0 indicates an ideal, unbiased model. As we aim to avoid both a biased and an anti-biased model, we calculate the absolute value of the Bias Score to measure the level of bias in LLMs. We also measure downstream task performance using the accuracy of Disambiguous questions. The questions are categorized as **Ambiguous** or **Disambiguous**. **Ambiguous** questions lack specific context within the text, making "Cannot be determined" the correct answer. In this case, if LLMs choose either social group for ambiguous questions, it indicates the presence of bias or anti-bias issues. **Disambiguous** questions provide an unambiguous context, with one of the two social group representations being the correct answer. Choosing the wrong group or "Cannot be determined" for Disambiguous questions can indicate a decline in downstream performance. Given that the BBQ dataset was not originally designed for multi-objective debiasing, we adapt our methodology by calculating the absolute value of the Bias Score in ambiguous contexts to assess bias levels accurately. An unbiased model achieves a Bias Score of 0, whereas a completely biased model reaches an absolute value of 1, encompassing both bias and anti-bias as manifestations of bias. For downstream task performance, we measure accuracy specifically in unambiguous contexts. We avoid using accuracy from ambiguous contexts, as it correlates closely with the Bias Score and does not adequately test the LLMs' capacity for logical reasoning. Since the BBQ dataset is not initially designed for multi-objective debiasing, we calculate the absolute value of the Bias score in ambiguous contexts to measure bias levels. An unbiased model has a Bias Score of 0, while an entirely biased model has an absolute value of 1,

where we consider bias and anti-bias as bias. We also measure downstream task performance using accuracy in disambiguous contexts, and we don't use accuracy from ambiguous contexts because it is heavily related to Bias Score and choosing unknown couldn't test the LLMs' logical abilities.. A robust and impartial Language Model will remain unbiased toward any social group when the text is insufficient and provide a logical answer when the text is adequate, resulting in a Bias Score of zero and 100% accuracy for disambiguous questions. As previously mentioned, we measure the multi-objective target of LLMs on the BBQ dataset using the Bias Score defined in (Parrish et al., 2022). The Bias Score ranges from -1 to 1: a positive value indicates a bias against the protected group, a negative value suggests anti-bias (i.e., bias against the dominant group not typically subjected to prejudice), and a Bias Score of 0 indicates an ideal, unbiased model. As we aim to avoid both a biased and an anti-biased model, in our experiments, we define a new metric, the Bias Score, calculated as the absolute value of the Bias Score defined in (Parrish et al., 2022).

The StereoSet dataset measures stereotypes across four domains, including Gender, Profession, Race, and Religion . As the model must provide probabilities, we adapt it into a QA format. Each question has three answer options: stereotype, anti-stereotype, and unrelated. Each question is posed six times in different sequences to mitigate order influence. We use three metrics defined in (Nadeem et al., 2020): Stereotype Score (ss), Language Modeling Score (lms), and Idealized CAT Score (icat) to measure the bias level, the performance on downstream tasks, and the overall multi-objective performance.

## A.2 Anti-Bias Prompts in Preliminary Experiments

Method	Prompts
ABP-0	Let's think about how to answer the question in a way that avoids bias or stereotyping.
ABP-1	Please ensure that your answer is unbiased and does not rely on stereotypes.
ABP-2	We should treat people from different socioeconomic statuses, sexual orientations, religions, races, physical appearances, nationalities, gender identities, disabilities, and ages equally. When we do not have sufficient information.
ABP-3	We should choose the unknown option, rather than making assumptions based on our stereotypes.
ABP-4	Really don't discriminate.

Table 6: Anti-Bias Prompts in Preliminary Experiments

## A.3 Main Experiments Results

Method	Bias Score	Delta(%)	Task Acc	Delta(%)
Baseline	0.13845	-	0.86365	-
Pure CoT	0.13079	-5.5	0.80173	-7.2
Society of Mind	0.17183	+24.1	0.83465	-3.3
using EquiSync methods				
Masking	<b>0.01696</b>	<b>-87.8</b>	0.81345	-5.8
Balancing	0.04281	-69.1	0.80502	-6.8
