

# ADAPT: ATTENTIVE SELF-DISTILLATION AND DUAL-DECODER PREDICTION FUSION FOR CONTINUAL PANOPTIC SEGMENTATION

**Anonymous authors**

Paper under double-blind review

## ABSTRACT

Panoptic segmentation, which unifies semantic and instance segmentation into a single task, has witnessed considerable success on predefined tasks. However, traditional methods tend to struggle with catastrophic forgetting and poor generalization when learning from a continuous stream of new tasks. Continual learning, emerged to tackle these challenges, has garnered increasing attention in recent years. Nonetheless, our study reveals that existing continual panoptic segmentation (CPS) methods often suffer from efficiency or scalability issues. To address these limitations, we propose a novel *dual-decoder* framework that incorporates *attentive self-distillation* and *prediction fusion* to efficiently preserve prior knowledge while facilitating model generalization. Specifically, we freeze the majority of model weights up to the pixel decoder, which is shared between the teacher and student models, thus enabling efficient knowledge distillation with only a single forward pass. Attentive self-distillation then adaptively distills useful knowledge from the old classes without distracting from non-object regions, which mitigates the inherent bias toward newly learned tasks. Additionally, query-level fusion (QLF) is devised to seamlessly integrate the output of the dual decoders without incurring scale inconsistency. Crucially, the computational overhead of our approach remains nearly constant, regardless of the number of continual learning steps or the number of classes introduced at each step. Our method achieves state-of-the-art performance on the ADE20K benchmark.

## 1 INTRODUCTION

Panoptic segmentation Kirillov et al. (2019b;a); Xiong et al. (2019); Wang et al. (2020); Cheng et al. (2020); Strudel et al. (2021); Cheng et al. (2021; 2022) is a fundamental task in computer vision that aims to provide a comprehensive understanding of visual scenes by unifying semantic segmentation and instance segmentation. It involves predicting semantic masks for *stuff* classes—amorphous background regions without distinct object boundaries, such as sky, road, and grass—and instance masks for *thing* classes, which are countable objects with well-defined boundaries like people, cars, and animals. This holistic task is crucial for various applications, including autonomous driving Cordts et al. (2016), robotics Ros et al. (2015), and image editing Aksoy et al. (2018).

In real-world scenarios, models are often required to continually adapt to new classes and evolving data distributions. To this end, continual learning (CL) has been developed to equip models with the capability to learn from a sequence of tasks while maintaining previously acquired knowledge. A key challenge in CL is known as *catastrophic forgetting*, where the model gradually loses information learned from earlier tasks due to the absence of previous class labels during new training stages. This issue has been extensively studied in classification Li & Hoiem (2017); Rebuffi et al. (2017), object detection Shmelkov et al. (2017); Liu et al. (2023) and semantic segmentation Cermelli et al. (2020); Douillard et al. (2021); Yang et al. (2023).

Despite this progress, continual panoptic segmentation (CPS) remains an under-investigated area with existing approaches exhibiting notable limitations. Concretely, CoMFormer Cermelli et al. (2023) finetunes the entire model on new tasks while employing knowledge distillation (KD) to mitigate forgetting. However, this approach presents three potential risks. First, finetuning the

entire model grants excessive plasticity, increasing the risk of *overfitting*. Second, although the final outputs are constrained by the distillation loss, the substantial plasticity in the intermediate layers can still lead to *catastrophic forgetting*. Lastly, updating the entire model using KD necessitates separate forward passes for the teacher and student models, significantly raising *computational costs*. Conversely, ECLIPSE Kim et al. (2024) seeks to preserve base performance by freezing most model weights, while continuously introducing additional learnable query features and embeddings for each new task. While this strategy helps maintain previously learned knowledge, it constrains the model’s capacity to generalize to new tasks due to *restricted plasticity*. Moreover, this approach encounters *scalability issues* as the number of tasks grows, complicating its practical applicability in more dynamic settings.

In this paper, we propose a novel approach for CPS that effectively balances base knowledge retention and learning new tasks. Building on Mask2Former Cheng et al. (2022), we freeze the image encoder and pixel decoder to preserve base knowledge and enhance efficiency. Concretely, this weight-freezing design allows for a shared forward pass between the teacher and student models, significantly reducing computational overhead. Note that the computational cost of our approach is invariant to the number of continual learning steps. By selectively finetuning only the cross-attention layers and feed-forward networks in the transformer decoder, our **adaptation strategy** optimally balances between plasticity (learning new information) and rigidity (retaining old knowledge).

To further alleviate forgetting, we develop an **attentive self-distillation** mechanism, inspired by focal loss Lin et al. (2017). Existing KD methods Cermelli et al. (2020); Douillard et al. (2021); Yang et al. (2023) often treat all entities (pixels or instances) uniformly, leading to an overemphasis on dominant background regions that provide little benefit in preserving prior knowledge. In contrast, our approach adaptively re-weights the contribution of each entity in the distillation loss based on the background confidence predicted by the teacher model. This modulated distillation can effectively concentrate on learning informative entities, enhancing the retention of previous knowledge.

Finally, recognizing that KD can still accumulate errors over successive learning steps, we propose a **dual-decoder prediction fusion** paradigm, where we retain the transformer decoder trained on the base dataset for subsequent inference. Specifically, we utilize this fixed decoder to predict base classes while the adapted decoder predicts novel classes learned up to the current step. To combine the predictions from these two decoders, we initially explore probability-level fusion (PLF), where the base-class probabilities predicted by the adapted decoder are replaced with those from the base decoder. However, this leads to scale inconsistencies between the combined base and novel class probabilities. To address this, we devise a more robust query-level fusion (QLF) strategy, which requires no probability fusion and thus avoids scale mismatches. Extensive experiments on the ADE20k benchmark showcase that our method outperforms state-of-the-art approaches in CPS.

Our contributions can be summarized as follows:

- We present an *efficient adaptation strategy* that freezes the image encoder and pixel decoder, allowing for shared forward passes between teacher and student models during distillation, significantly reducing computational overhead.
- We develop an *attentive self-distillation* loss, which emphasizes informative entities (or queries) and down-weights less useful ones based on background confidence, improving the preservation of prior knowledge.
- We devise a *dual-decoder prediction fusion* mechanism, dubbed as query-level fusion (QLF), which combines the outputs of the base and adapted decoders without relying on probability fusion, effectively preventing the scale inconsistency issue present in PLF.
- Our method, **ADAPT**, outperforms current CPS approaches, achieving superior results on the ADE20k benchmark.

## 2 RELATED WORKS

### 2.1 PANOPTIC SEGMENTATION

Panoptic segmentation, introduced by Kirillov et al. (2019b), aims to unify semantic and instance segmentation, with Panoptic FPN Kirillov et al. (2019a) extending this concept using a feature pyra-

mid network for both *stuff* and *thing* classes. UPSNet Xiong et al. (2019) improved efficiency by introducing a learnable panoptic head, while Axial-DeepLab Wang et al. (2020) leveraged axial attention to enhance spatial feature representation. Panoptic-DeepLab Cheng et al. (2020) streamlined panoptic segmentation using pixel-level classification in a fully convolutional framework. Transformers further advanced the field with MaskFormer Cheng et al. (2021), which introduced mask classification, simplifying segmentation. Mask2Former Cheng et al. (2022) extended this by providing a generalized, transformer-based framework for universal segmentation tasks, achieving state-of-the-art performance. For a fair comparison, we adopt the Mask2Former framework, consistent with prior works on continual panoptic segmentation Cermelli et al. (2023); Kim et al. (2024).

## 2.2 CONTINUAL PANOPTIC SEGMENTATION

Continual panoptic segmentation remains a relatively under-explored field, with initial efforts focusing on addressing the challenge of catastrophic forgetting. Building upon the transformer-based architecture Mask2Former Cheng et al. (2022), CoMFormer Cermelli et al. (2023) employs knowledge distillation and mask-based pseudo-labeling to mitigate forgetting when finetuning the entire model. However, this approach yields suboptimal base class performance due to error accumulation over continual learning steps. ECLIPSE Kim et al. (2024) improves base class retention by freezing the majority of model weights and progressively introduces learnable prompt features to handle new tasks. While this strategy improves rigidity, it limits the model’s plasticity and raises scalability issues as additional prompts are required for each task. To resolve these limitations, we propose a novel approach that effectively preserves base knowledge while maintaining strong generalization ability, without incurring scalability issues.

## 2.3 SELF DISTILLATION

Unlike traditional knowledge distillation Hinton et al. (2015), which typically employs larger teacher models to guide smaller student models, self-distillation leverages the same architecture to transfer knowledge gained in earlier stages to improve performance in later stages. This technique has been applied across various domains to mitigate forgetting, including classification Li & Hoiem (2017); Rebuffi et al. (2017); Zhang et al. (2021), object detection Shmelkov et al. (2017); Liu et al. (2023), semantic segmentation Cermelli et al. (2020); Douillard et al. (2021); Yang et al. (2023), and panoptic segmentation Cermelli et al. (2023). However, most of these methods require separate forward passes for the teacher and student models, resulting in considerable computational overhead. To overcome this limitation, we propose to share a single forward pass for the majority of modules between the teacher and student models. By freezing the model up to the pixel decoder and adapting only the final decoder, our approach achieves a double benefit—improving efficiency and retaining base knowledge.

# 3 METHOD

## 3.1 PRELIMINARY

**Problem Setting.** Panoptic segmentation is a challenging task that aims to unify semantic segmentation and instance segmentation. It predicts semantic masks for ‘stuff’ classes (amorphous, background regions without distinct object boundaries, e.g., sky, road, grass) and instance masks for ‘thing’ classes (countable object classes with distinct boundaries, e.g., people, cars, animals). In the context of continual learning, the objective is to train a model across a sequence of tasks (or steps)  $t = 0, 1, 2, \dots, T$ . At each step  $t$ , a new training set  $\mathcal{D}^t = \{(x_j, y_j)\}_{j=1}^{N_t}$  is available, where each input image  $x_j$  contains at least one new-class mask label, i.e.,  $|y_j| \neq 0$ . Importantly, at step  $t$ , only the current class labels  $y_j \in \mathcal{C}^t$  are available, while the labels from previous steps  $\mathcal{C}^{0:t-1}$  or future steps  $\mathcal{C}^{t+1:T}$  are inaccessible, even though these classes may still appear in the input image. This scenario is known as the *overlapped* setting Cermelli et al. (2020). Following the convention in continual learning, the class subsets across tasks are disjoint. A special class label  $\emptyset$  represents “no object” detected for a given query, akin to the “background” class in traditional segmentation methods Chen et al. (2017). Once all learning steps are completed, the model is evaluated on the full set of classes  $\mathcal{C}^{0:T}$  encountered throughout training.

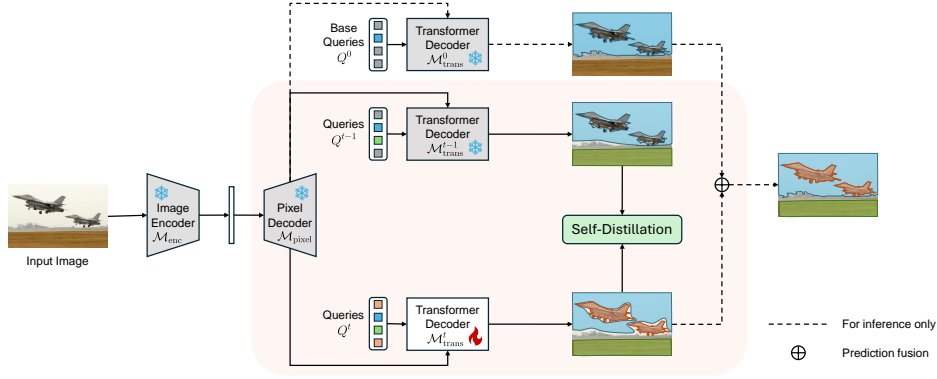

Figure 1: Overview of the proposed dual-decoder framework for continual panoptic segmentation. During training, attentive self-distillation is applied between  $\mathcal{M}_{\text{trans}}^{t-1}$  and  $\mathcal{M}_{\text{trans}}^t$ . During inference, the fixed base decoder  $\mathcal{M}_{\text{trans}}^0$  predicts base classes, while the adapted decoder  $\mathcal{M}_{\text{trans}}^t$  handles novel classes. We apply query-level fusion (QLF) to effectively combine the outputs of these two decoders and preventing scale mismatches. More details can be found in Sec. 3.2 and Sec. 3.3.

**Model Architecture.** We adopt Mask2Former Cheng et al. (2022), a widely used transformer-based model for universal segmentation tasks. Given an input image  $x$ , the image encoder  $\mathcal{M}_{\text{enc}}$  first extracts low-resolution features. These features are then progressively upsampled by the pixel decoder  $\mathcal{M}_{\text{pixel}}$  to generate high-resolution per-pixel embeddings. The transformer decoder  $\mathcal{M}_{\text{trans}}$  utilizes a set of learnable object queries  $Q = \{q_i\}_{i=1}^{N_q}$ , which interact with the feature pyramid output by the pixel decoder via cross-attention. For each query  $q_i$ , the decoder outputs a binary mask  $M_i \in \mathbb{R}^{\frac{H}{s} \times \frac{W}{s}}$  with associated class probabilities  $p_x(i, c) \in \mathbb{R}^{N_c+1}$ , where  $H$  and  $W$  denote the spatial dimensions of the input image,  $s$  is the stride and  $N_c$  the number of classes. This architecture offers two key advantages: (1) compared to per-pixel classification Long et al. (2015), mask classification enables better differentiation between objects, making it ideal for panoptic segmentation, and (2) its DETR-style Carion et al. (2020) end-to-end set prediction eliminates the need for a cumbersome two-stage process He et al. (2017), resulting in a more efficient and streamlined framework.

### 3.2 ADAPTATION STRATEGY

Continual panoptic segmentation has been scarcely explored. The existing method, CoMFormer Cermelli et al. (2023), finetunes the entire model on the new sequence of tasks, which often leads to significant degradation in the performance of base classes. To mitigate this issue, Kim et al. Kim et al. (2024) freeze most of the model’s weights, allowing only the newly introduced learnable queries (or prompts) to be updated. While this mechanism helps maintain base class performance (rigidity), it compromises the model’s ability to generalize to new tasks (plasticity). In this work, we freeze the image encoder  $\mathcal{M}_{\text{enc}}$  and pixel decoder  $\mathcal{M}_{\text{pixel}}$  for efficiency and systematically investigate the effects of fine-tuning different components of the transformer decoder  $\mathcal{M}_{\text{trans}}$ , which consists of  $L$  transformer blocks each with self-attention layers  $\{\text{SA}_i\}_{i=1}^L$ , cross-attention layers  $\{\text{CA}_i\}_{i=1}^L$  and feed-forward networks  $\{\text{FFN}_i\}_{i=1}^L$ . We observe that freezing the image encoder  $\mathcal{M}_{\text{enc}}$  and pixel decoder  $\mathcal{M}_{\text{pixel}}$  significantly reduces catastrophic forgetting while preserving considerable generalization capacity. Additionally, it enables the feasibility of our self-distillation design, which relies on the shared and frozen weights. For the transformer decoder  $\mathcal{M}_{\text{trans}}^t$ , we fine-tune only the cross-attention layers and the feed-forward networks (FFN), striking an ideal balance between rigidity and plasticity, along with high efficiency. Detailed experimental results can be found in Sec. 4.5.2.

### 3.3 ATTENTIVE SELF-DISTILLATION

Even though only the transformer decoder is updated during continual learning, the forgetting issue persists as the previous class labels  $\mathcal{C}^{0:t-1}$  are no longer available. To mitigate this issue, we resort to knowledge distillation, which penalizes the discrepancies between the predicted class probabilities of the teacher model  $\mathcal{T}$  and student model  $\mathcal{S}$  given the same input. Following the prior method Yang et al. (2023) in continual semantic segmentation, we opt to establish correct class correspondences for knowledge distillation by modifying the old model outputs. Notably, the natural bias toward

newly learned classes in continual learning results in false negatives (FN) for base classes and false positives (FP) for novel classes, degrading both base and novel class performance. Consequently, the key objective is to mitigate this bias using the knowledge from the previous classes  $\mathcal{C}^{0:t-1}$ . To this end, we apply knowledge distillation only to the queries  $\mathcal{B}$  that are not matched with any new classes  $\mathcal{C}^t$  in the bipartite matching Carion et al. (2020), which can be formulated as:

$$\ell_{\text{kd}}^{\theta^t}(x, y) = -\frac{1}{|\mathcal{B}|} \sum_{i \in \mathcal{B}} \sum_{c \in \mathcal{C}^{0:t} \cup \{\emptyset\}} \hat{p}_x^{t-1}(i, c) \log p_x^t(i, c), \quad (1)$$

where  $p_x^t(i, c)$  refers to the probability of class  $c$  for query  $q_i^t$  predicted by  $\mathcal{M}_{\text{trans}}^t$ , and  $\hat{p}_x^{t-1}(i, c)$  is the probability  $p_x^{t-1}(i, c)$  predicted by  $\mathcal{M}_{\text{trans}}^{t-1}$ , expanded with zero probability for the added novel classes  $c \in \mathcal{C}^t$ , formally as:

$$\hat{p}_x^{t-1}(i, c) = \begin{cases} 0 & \text{if } c \in \mathcal{C}^t \\ p_x^{t-1}(i, c) & \text{otherwise.} \end{cases} \quad (2)$$

However, this distillation loss treats all queries equally, despite the fact that over 95% of queries contain no object. This can cause the model to overemphasize these dominant no object regions, which contribute little to preserving previously learned knowledge. To address this issue, we propose adaptively re-weighting the contribution of each query within the distillation loss. Inspired by focal loss Lin et al. (2017), we incorporate a modulating term  $\alpha(1 - \hat{p}_x^{t-1}(i, \emptyset))^\gamma$  into the distillation loss, resulting in our adaptive weighted version:

$$\bar{\ell}_{\text{kd}}^{\theta^t}(x, y) = -\frac{1}{|\mathcal{B}|} \sum_{i \in \mathcal{B}} \alpha(1 - \hat{p}_x^{t-1}(i, \emptyset))^\gamma \sum_{c \in \mathcal{C}^{0:t} \cup \{\emptyset\}} \hat{p}_x^{t-1}(i, c) \log p_x^t(i, c), \quad (3)$$

where  $\gamma \geq 0$  is a tunable focusing parameter and  $\alpha > 0$  is a scaling factor. When  $\gamma > 1$ , this modulating term down-weights queries that are predicted as no object with high confidence ( $\hat{p}_x^{t-1}(i, \emptyset) \rightarrow 1$ ) by the old model. The parameter  $\gamma$  controls the shape of the re-weighting curve. Specifically, the larger value of  $\gamma$  extends the flat range of the curve and down-weights more no object queries with lower confidence. In addition, the scaling factor  $\alpha$  allows the modulating term to be greater than one, making it possible to emphasize the contribution of object queries ( $\hat{p}_x^{t-1}(i, \emptyset) \rightarrow 0$ ). When  $\gamma = 0$ , the proposed adaptive re-weighted KD loss reduces to the standard non-re-weighting version. We empirically observe that  $\gamma = 3$  and  $\alpha = 4$  yields the best results.

**Discussion.** We highlight the distinction of our adaptive re-weighted self-distillation in three aspects. First, thanks to our model freezing and adaptive decoder design, the teacher model and student model share the same weights up to the pixel decoder  $\mathcal{M}_{\text{pixel}}$ . Unlike traditional knowledge distillation (KD) based methods Cermelli et al. (2023); Douillard et al. (2021), which require separate forward passes for the teacher model and student model, our approach performs only a single forward pass except for the final dual decoders  $\mathcal{M}_{\text{trans}}^{t-1}$  and  $\mathcal{M}_{\text{trans}}^t$ , manifesting higher efficiency. Second, in contrast to Kim et al. (2024), which encounters scalability issues due to the continual introduction of new prompt features and embeddings for each new task, our design remains invariant to the number of tasks  $T$  or the number of classes  $|\mathcal{C}^t|$  within each task  $t$ , allowing for greater scalability. Third, distinct to Cermelli et al. (2023), which applies unbiased KD Cermelli et al. (2020) to all queries, our approach selectively applies modulated KD only to queries that are not matched with any new class, thereby maintaining old knowledge more effectively and efficiently.

### 3.4 DUAL-DECODER PREDICTION FUSION

Although knowledge distillation has been adopted to alleviate catastrophic forgetting, it tends to accumulate errors over successive continual learning steps, devastating old knowledge learned in the early stage. This challenge motivates us to retain the transformer decoder  $\mathcal{M}_{\text{trans}}^0$  trained on the base dataset  $\mathcal{D}^0$ , as it contains precise knowledge for decoding useful information from the feature pyramid output by the pixel decoder  $\mathcal{M}_{\text{pixel}}$ . In particular, only the weights of the cross-attention layers and the feed-forward networks need to be stored, since the self-attention layers are fixed and shared across all learning steps. Notably, the retained base decoder does not participate in the training phase, resulting in no additional computational overhead. During inference, the base decoder  $\mathcal{M}_{\text{trans}}^0$  is used to predict masks for the base classes  $\mathcal{C}^0$ , while the adapted decoder  $\mathcal{M}_{\text{trans}}^t$  handles the new classes  $\mathcal{C}^{1:t}$  learned up to the current step  $t$ .

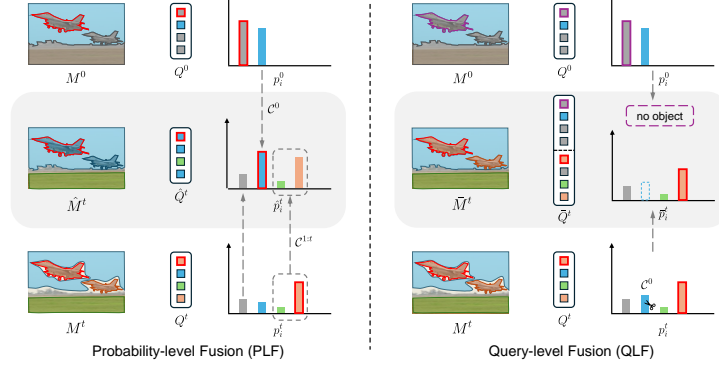

Figure 2: Illustration of probability-level fusion (PLF) and query-level fusion (QLF).

**Probability-level fusion.** As the transformer decoders  $\mathcal{M}_{\text{trans}}^0$  and  $\mathcal{M}_{\text{trans}}^t$  are responsible for predicting base and novel classes respectively, an effective mechanism is needed to combine their outputs for the final predictions. One straightforward method, which we refer to as probability-level fusion (PLF), is to replace the base-class  $c \in \mathcal{C}^0$  probability scores  $p_{i,c}^t$  (for brevity, we omit  $x$  in  $p_x^t(i, c)$  and use the subscript  $i, c$ ) predicted by  $\mathcal{M}_{\text{trans}}^t$  with the corresponding scores  $p_{i,c}^0$  predicted by  $\mathcal{M}_{\text{trans}}^0$ . The combined predicted mask  $\hat{M}_i^t$  for query  $\hat{q}_i^t$  is then obtained by selectively choosing between the masks  $M_i^0$  and  $M_i^t$  predicted by the base and adapted decoders, respectively. Specifically, the combined probability score  $\hat{p}_{i,c}^t$  and mask  $\hat{M}_i^t$  are given by:

$$\hat{p}_{i,c}^t = \begin{cases} p_{i,c}^0 & \text{if } c \in \mathcal{C}^0, \\ p_{i,c}^t & \text{otherwise,} \end{cases} \quad \hat{M}_i^t = \begin{cases} M_i^0 & \text{if } \hat{c}_i \in \mathcal{C}^0, \\ M_i^t & \text{otherwise.} \end{cases} \quad (4)$$

where  $\hat{c}_i = \arg\max_c \hat{p}_{i,c}^t$  represents the class with the highest combined probability score. However, this approach can lead to inconsistencies between the probability scales of base and novel classes, as they are not optimized on the same data distribution. We observe that base-class probabilities tend to have larger values than novel-class probabilities, which can lead to confusion between base and novel classes. For instance, as shown in Fig. 2, the novel class “airplane” is misclassified as the base class “sky” due to this discrepancy in probability-level fusion.

**Query-level fusion.** In light of the inconsistency issue in PLF, we propose query-level fusion (QLF) as a simple yet effective alternative. As illustrated in Fig. 2, we discard the base-class probabilities  $p_{i,c}^t (c \in \mathcal{C}^0)$  predicted by  $\mathcal{M}_{\text{trans}}^t$  so that the adapted decoder only makes predictions for novel classes. Conversely,  $\mathcal{M}_{\text{trans}}^0$  is solely responsible for predicting the base classes. In this way, the “airplane”, though with high confidence in the base class “sky”, can be correctly suppressed by the “no object” class with even higher confidence, effectively rectifying the confusion that otherwise occurred in PLF. During query-level fusion, the more accurate sky mask with a finer boundary, predicted by the base decoder, supersedes the less precise version generated by the adapted decoder, successfully eliminating error accumulation. This process is achieved using the standard panoptic inference procedure in Mask2Former Cheng et al. (2022).

## 4 EXPERIMENTS

### 4.1 DATASET AND EVALUATION METRICS

We validate the effectiveness of our approach on the ADE20K Zhou et al. (2017) and COCO Lin et al. (2014) benchmark. ADE20K consists of 25,574 training images and 2,000 validation images. This dataset includes a total of 150 classes, divided into 100 “thing” classes and 50 “stuff” classes. Unlike COCO Lin et al. (2014), which averages 7.7 instances and 3.5 classes per image, and Pascal VOC Everingham et al. (2010), which averages 2.3 instances and 1.4 classes per image, ADE20K contains an average of 19.5 instances and 9.9 classes per image. The complexity of scenes in ADE20K makes it a challenging benchmark for continual panoptic segmentation. COCO consists of 118,287 training images and 5,000 validation images with 133 classes. We leave the COCO results in the Appendix. We adopt the conventional Panoptic Quality (PQ) Kirillov et al. (2019b)

metric used in panoptic segmentation, which is defined as the product of Recognition Quality (RQ) and Segmentation Quality (SQ):

$$PQ = RQ \times SQ = \underbrace{\frac{|TP|}{|TP| + \frac{1}{2}|FP| + \frac{1}{2}|FN|}}_{\text{Recognition Quality (RQ)}} \times \underbrace{\frac{\sum_{(p,g) \in TP} \text{IoU}(p,g)}{|TP|}}_{\text{Segmentation Quality (SQ)}},$$

where  $\text{IoU}(p, g)$  is the Intersection-over-Union between a predicted segment  $p$  and a ground truth segment  $g$ .  $TP$ ,  $FP$ , and  $FN$  represent true positives, false positives, and false negatives, respectively. RQ measures how well the model detects and classifies objects, while SQ evaluates how well the predicted segments match the ground truth in terms of shape and overlap.

## 4.2 BASELINES AND CONTINUAL PROTOCOLS

We adhere to the continual panoptic segmentation protocol from ECLIPSE Kim et al. (2024), evaluating both 100- $n$  ( $n = 5, 10, 50$ ) and 50- $n$  ( $n = 10, 20, 50$ ) scenarios. For instance, 100-10 refers to base training with 100 classes, followed by 5 incremental steps, each introducing 10 new classes. Note that a smaller  $n$  results in more continual steps, making the scenario more challenging. We re-implement the representative methods MiB Cermelli et al. (2020) and PLOP Douillard et al. (2021), originally developed for continual semantic segmentation, as competitive baselines. Additionally, we include the state-of-the-art methods CoMFormer Cermelli et al. (2023) and ECLIPSE Kim et al. (2024), which are specifically designed for continual panoptic segmentation, in our evaluation. Alongside these, we also evaluate the simplest baseline, FT (Fine-Tuning), which finetunes the base model on new tasks without any specific continual learning design. All experiments are conducted under the *overlap* setting, following the latest state-of-the-art approach Kim et al. (2024). After the final step  $T$ , we evaluate performance on base classes ( $\mathcal{C}^0$ ), novel classes ( $\mathcal{C}^{1:T}$ ), and the full set of classes ( $\mathcal{C}^{0:T}$ , denoted as *all*).

## 4.3 IMPLEMENTATION DETAILS

Following state-of-the-art methods Cermelli et al. (2023); Kim et al. (2024), we adopt the Mask2Former Cheng et al. (2022) model with an output stride of 4, using ResNet-50 He et al. (2016) as the backbone, unless otherwise stated. To ensure fairness, we follow the same training hyperparameters as our competitors Cermelli et al. (2023); Kim et al. (2024), with the exception of using a higher learning rate, which leads to faster convergence and slightly improved performance. The initial learning rate is set to  $10^{-4}$  for all steps in the 100- $n$  settings. In the 50- $n$  settings, we use  $2 \times 10^{-4}$  for the incremental steps ( $t > 0$ ), while maintaining  $10^{-4}$  during base training ( $t = 0$ ). We train the network for 160k iterations during base training, and for 400 iterations per class in all subsequent steps. The batch size is consistently set to 16 across all settings. We use the AdamW optimizer Loshchilov & Hutter (2018) with the same weight decay values as in Cheng et al. (2022). For all settings, we report Panoptic Quality (PQ) results on the standard validation set. All experiments are conducted using two NVIDIA RTX 6000 Ada GPUs.

## 4.4 PERFORMANCE

As shown in Table 1, the FT baseline fails to retain previous knowledge due to the absence of anti-forgetting mechanisms. This leads to catastrophic forgetting, not only of base class knowledge but also of the new classes learned in earlier steps, resulting in poor overall performance on novel classes. MiB Cermelli et al. (2020) and PLOP Douillard et al. (2021) demonstrate significant improvements over FT, thanks to unbiased knowledge distillation and multi-scale local POD distillation. CoMFormer Cermelli et al. (2023) improves performance further, particularly in the 100- $n$  settings, surpassing PLOP by +5.5 PQ on base classes in the 100-10 scenario. ECLIPSE Kim et al. (2024) mitigates the forgetting issue by only updating newly introduced prompts, which brings improvements on base classes, such as a +5.2 PQ gain over CoMFormer in the 100-10 setting. Our approach, FDAS, consistently surpasses all state-of-the-art methods across all scenarios. In the 100-10 setting, FDAS outperforms CoMFormer and ECLIPSE on both base (+6.2/+1.0 PQ) and novel (+9.2/+9.8 PQ) classes, achieving 42.2 PQ on base classes and 26.3 PQ on novel classes. In the more challenging 50-10 scenario, FDAS exceeds CoMFormer and ECLIPSE by +11.0/+5.7 PQ on base classes and +3.1/+4.5 PQ on novel classes, respectively. Beyond its strong performance,

Method	100-5 (11 tasks)			100-10 (6 tasks)			100-50 (2 tasks)		
	1-100	101-150	all	1-100	101-150	all	1-100	101-150	all
FT <sup>†</sup>	0.0	1.3	0.4	0.0	2.9	1.0	0.0	25.8	8.6
MiB <sup>†</sup> Cermelli et al. (2020)	24.0	6.5	18.1	27.1	10.0	21.4	35.1	19.3	29.8

Table 1: **Continual panoptic segmentation results (PQ)** on the ADE20K Zhou et al. (2017) benchmark, with the number of base classes  $|\mathcal{C}^0|$  set to (a) 100 and (b) 50. All methods are based upon the Mask2Former framework Cheng et al. (2022). The *joint* setting indicates that all classes are trained simultaneously in an offline manner. <sup>†</sup> and <sup>‡</sup> indicate results taken from Cermelli et al. (2023) and Kim et al. (2024), respectively. \* denotes results reproduced using the official code.

Adaptation Strategy	Attentive Self-Distillation	Prediction Fusion	100-10 (6 tasks)		
			1-100	101-150	all
✓			36.0	17.1	29.7
✓			38.3	20.1	32.3
✓	✓		37.2	22.6	32.4
✓		✓	42.4	22.8	35.8
✓	✓	✓	42.2	26.3	36.9

Table 2: **Effect of the proposed components.** Without attentive self-distillation, unbiased KD serves as the baseline. When the adaptation strategy is omitted, weight-shared self-distillation becomes infeasible, and the entire old model is used as the teacher model.

FDAS offers a computational advantage by utilizing a single-forward self-distillation design, unlike MiB, PLOP, and CoMFormer, which require double forward passes. Compared to ECLIPSE, our FDAS balances strong base performance with enhanced generalization capacity, made possible by the complementary fixed and adaptive decoders combined with self-distillation.

#### 4.5 ABLATION STUDY

We conducted ablation studies on the ADE20K 100-10 setting, which involves multiple continual learning steps and presents significant challenges.

##### 4.5.1 OVERALL STUDY

As shown in Table 2, each proposed component contributes incrementally to improving performance. Our adaptation strategy improves both base and novel performance, showing enhanced plasticity and rigidity in balance. Incorporating attentive self-distillation further boosts novel class performance since the inherent bias toward new classes is alleviated. As expected, prediction fusion substantially enhances knowledge retention, resulting in a negligible decline compared to *joint training*. Finally, combining all three components yields the best results, demonstrating that the proposed components are complementary to each other. In summary, our approach offers a well-balanced and efficient solution for continual panoptic segmentation.

FFN	Self-att (SA)	Cross-att (CA)	Trainable Params	<b>100-10</b> (6 tasks)

Table 4: Effect of  $\alpha$  and  $\gamma$  in the attentive self-distillation loss.

#### 4.5.2 ADAPTATION STRATEGY

We fixed the weights of the image encoder and pixel decoder for two key reasons. First, finetuning these two components does not enhance the model’s generalization capacity, yet it substantially increases the risk of overfitting and computational cost, making it an inefficient trade-off. In contrast, freezing the image encoder and pixel decoder helps alleviate the forgetting issue since their weights are preserved to retain base knowledge. Interestingly, comparing the first two rows of Table 2, the transformer decoder itself (ablated in the following paragraph) demonstrates sufficient learning capability to generalize to new tasks. Second, this design allows a large portion of weights to be shared between the teacher model and the student model during knowledge distillation, which we refer to as self-distillation.

Based on this, we investigate the impact of fine-tuning different components within the transformer decoder, as presented in Table 3. Finetuning the FFN alone yields strong results (23.6 PQ) on novel classes, while cross-attention (CA) or self-attention (SA) alone shows limited generalization ability. It highlights the critical role of FFN in enhancing model generalization. The best performance is achieved when both FFN and CA are finetuned together, reaching 26.3 PQ on novel classes and 36.9 PQ overall. In contrast, finetuning all components or combining FFN with SA does not lead to substantial gains, indicating that the combination of FFN and CA offers the most effective improvement in generalization without overfitting.

#### 4.5.3 ATTENTIVE SELF-DISTILLATION

As shown in Table 4, the effect of the attentive self-distillation is influenced by the modulation factors  $\alpha$  and  $\gamma$ . When  $\gamma = 0$ , the attentive self-distillation loss degrades to the uniform version, which results in poorer performance on novel classes (e.g., PQ drops to 17.1 and 15.7 for  $\alpha = 2$  and  $\alpha = 4$ , respectively) regardless of different values of  $\alpha$ . This can be attributed to the overwhelming influence of the dominant no object regions, which diverts the distillation process away from informative old class objects. As  $\gamma$  increases, the attentive self-distillation can effectively focus on informative regions (old classes  $\mathcal{C}^{0:t-1}$ ), resulting in improved novel performance. This is because, without retention of old knowledge, the base classes will be misclassified as novel classes due to the inherent bias in continual learning, leading to false positive predictions for novel classes and hence

Fusion Strategy	<b>100-10</b> (6 tasks)

ADAPT (Ours)	12.12M	<b>4k</b>	<b>2.27 hrs</b>	105.76G	7127 MB	48.3 ms	<b>42.2</b>	<b>26.3</b>	<b>36.9</b>

Table 6: **Efficiency comparison on both training and inference phases.** The training time is reported using two NVIDIA RTX 6000 Ada GPUs. FLOPs, GPU memory usage, and time cost are calculated on a per-image, per-device basis during inference with the same device setup.

lowering PQ. In contrast, these mistakes can be effectively corrected by our attentive self-distillation with a concentration on informative old classes. Specifically, the combination of  $\alpha = 4$  and  $\gamma = 3$  yields the highest overall PQ of 36.9, striking a balance between retaining base knowledge (42.2 PQ) and learning novel classes (26.3 PQ). This demonstrates the effectiveness of re-weighting the contribution of queries based on no object confidence, allowing the model to concentrate on preserving previous knowledge while efficiently learning new information.

#### 4.5.4 DUAL-DECODER PREDICTION FUSION

As shown in Table 5, without any fusion strategy, the model struggles to retain base knowledge due to accumulated errors over multiple learning steps. Introducing probability-level fusion (PLF), where base-class probabilities are replaced by those from the base decoder, significantly boosts base performance to 43.1 PQ. However, PLF negatively affects novel classes, reducing PQ from 22.6 to 20.8, due to scale inconsistency between the base and novel class probabilities. In contrast, query-level fusion (QLF) resolves this inconsistency by eliminating the need for probability fusion, resulting in a more balanced performance across both base and novel classes and yielding the highest overall PQ of 36.9.

#### 4.5.5 EFFICIENCY

In Table 6, we can see that our approach requires only 2.27 hours in total for five training steps, saving 48% and 53% training times compared to CoMFormer Cermelli et al. (2023) and ECLIPSE Kim et al. (2024) respectively. This is because ADAPT does not require dual-model forward during training, as opposed to CoMFormer. Moreover, thanks to our efficient adaptation strategy, we yield 4 times faster adaptation speed than ECLIPSE, which leads to shorter training time costs. As for inference, our method marginally adds 6.5% computational cost, while yields significant performance improvement. Our inference speed maintain comparable to CoMFormer, showing the efficiency of our approach.

## 5 CONCLUSION

In this paper, we propose a novel approach for continual panoptic segmentation (CPS) that effectively balances the retention of base knowledge and learning new tasks. Concretely, we present an *efficient adaptation strategy* that freezes the image encoder and pixel decoder, allowing shared forward passes between the teacher and student models, significantly saving computational costs. We also introduce an *attentive self-distillation* loss that emphasizes informative queries based on background confidence during distillation, which effectively enhances knowledge retention. Additionally, we devise a *dual-decoder query-level fusion* technique that avoids the scale inconsistency problems occurred in probability-level fusion. Our method, **ADAPT**, demonstrates superior performance on the ADE20k benchmark, showcasing its effectiveness and scalability in continual learning.

## A APPENDIX

### A.1 CONTINUAL PANOPTIC SEGMENTATION ON THE COCO BENCHMARK

We evaluate our approach on the COCO panoptic segmentation benchmark Lin et al. (2014), which consists of 118,287 training images and 5,000 validation images distributed across 133 classes. In alignment with Kim et al. (2024), we use 83 base classes and incrementally add 50 additional classes. It is important to note that the class ordering in COCO panoptic segmentation follows a sequence of “things” and “stuff”. We report results based on a randomly shuffled class order as proposed by Kim et al. (2024), given by the following sequence:

[1, 3, 10, 47, 58, 9, 88, 16, 126, 120, 17, 129, 35, 119, 59, 57, 54, 90, 75, 38, 80, 48, 131, 56, 95, 25, 43, 2, 68, 110, 32, 14, 29, 11, 7, 52, 83, 102, 84, 73, 5, 45, 117, 93, 87, 46, 118, 34, 61, 19, 77, 111, 63, 98, 130, 66, 79, 97, 33, 86, 127, 104, 64, 49, 36, 6, 91, 50, 112, 8, 65, 132, 92, 27, 122, 22, 51, 85, 115, 28, 89, 70, 62, 12, 101, 108, 125, 123, 39, 81, 20, 40, 41, 114, 128, 74, 18, 99, 100, 60, 30, 124, 69, 37, 13, 23, 116, 55, 26, 121, 71, 67, 106, 133, 42, 107, 105, 109, 82, 103, 76, 94, 24, 15, 78, 53, 21, 96, 72, 113, 44, 31, 4].

We compare our method with two baseline approaches, PLOP Douillard et al. (2021) and CoMFormer Cermelli et al. (2023), with the ResNet-50 backbone network under the *overlap* setting. As illustrated in Table 7, our approach outperforms these baselines by significant margins.

Method	83-5 (11 tasks)			83-10 (6 tasks)		
	1-83	84-133	all	1-83	84-133	all
CoMFormer Cermelli et al. (2023)				37.3	26.6	33.3

Table 8: Continual Panoptic Segmentation results (PQ) on the ADE20K Zhou et al. (2017) benchmark under the *disjoint* setting. All approaches are based on the same framework Mask2Former Cheng et al. (2022) with the ResNet-50 He et al. (2016) backbone.

## A.2 IMPACT OF CLASS ORDERING ON PERFORMANCE

We examine the robustness of our method with respect to variations in class ordering. We conduct experiments on the ADE20K panoptic segmentation 100–10 scenario, utilizing the 10 randomly shuffled class orders proposed by Kim et al. (2024) for consistency. The PQ distributions are presented in Figure 3 through boxplots. Notably, our method ADAPT exhibits strong resilience to changes in class ordering, consistently outperforming alternative methods.

## A.3 CONTINUAL PANOPTIC SEGMENTATION IN THE DISJOINT SETTING

The pioneering work of Cermelli et al. (2020) introduced two distinct settings for continual learning: *disjoint* and *overlap*. While the *overlap* setting is generally considered more challenging and realistic, we focused primarily on it in our main paper. In this section, we present experimental results for continual panoptic segmentation on ADE20K Zhou et al. (2017) under the *disjoint* setting. The results, as summarized in Table 8, highlight the superior performance of ADAPT over existing methods in continual panoptic segmentation.
