Paper under double-blind review

ABSTRACT

Open-weight LLMs are particularly appealing choices to generate training data for fine-tuning Code LLMs on domain-specific service robot applications because they are cost-effective, customizable, and offer better privacy protection. However, unlike proprietary LLMs, open-weight models are more error-prone and often produce programs that violate domain-specific constraints. A promising solution is to incorporate a robot simulator with a well-defined environment to verify program correctness. Yet, these environments require pre-enumeration of relevant entities and their states, which limits the diversity of programs that can be effectively verified. In this work, we introduce ROBO-INSTRUCT that preserves the diversity of programs generated by an LLM while providing the correctness of simulator-based checking. ROBO-INSTRUCT introduces ROBOSIM to dynamically synthesize consistent simulation environments for each generated program. Moreover, ROBO-INSTRUCT handles subtler instruction-program inconsistencies that do not result in a constraint violation via INSTALIGN, an LLM-aided instructionprogram alignment process. Given domain-specific APIs and a few seed examples, ROBO-INSTRUCT can leverage an 8B Llama3 model to generate a training dataset for fine-tuning a 7B CodeLlama model. Our fine-tuned model achieves a 28.75% improvement in pass@1 over the original base model and a 13.75% improvement compared to its SELF-INSTRUCT-finetuned counterparts, even surpassing the performance of a few proprietary LLMs, such as GPT-3.5-Turbo and Gemini-Pro.

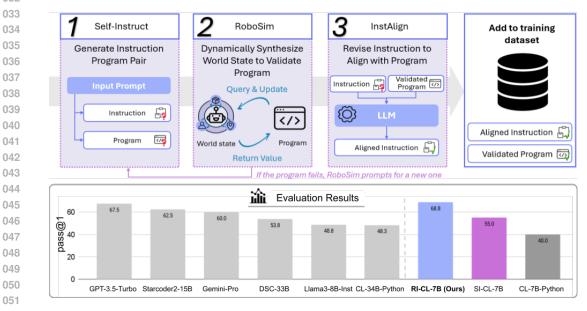

Figure 1: High-level overview of the ROBO-INSTRUCT framwork. This figure also shows the pass@1
 score performance of ROBO-INSTRUCT fine-tuned LLM compared to other LLMs on ROBOEVAL.

054 1 INTRODUCTION

056 057

Large language models (LLMs) have shown great promise at leveraging domain-specific application programming interfaces (APIs) and generating robot programs from natural language instructions (Hu et al., 2024; Huang et al., 2023b; Biggie et al., 2023; Liu et al., 2023a; Wu et al., 2023; Liang et al., 060 2022; Singh et al., 2023; Huang et al., 2023a). For instance, by formulating a robot's navigation 061 and perception skills into APIs, such as go_to (location) and is_in_room (object), an 062 LLM can generate a program for a service mobile robot to complete the task: "Determine the 063 number of conference rooms without markers". However, despite impressive results, the performance 064 gap remains wide between proprietary and open-weight LLMs in generating robot programs from domain-specific APIs (Hu et al., 2024). To bridge the performance gap, SELF-INSTRUCT (Wang 065 et al., 2022) is a popular method for generating domain-specific data for finetuning LLMs. Given 066 the definition of APIs and a few seed task examples, SELF-INSTRUCT prompts an LLM to generate 067 diverse instruction-program pairs as training data. 068

data, for the fine-tuning of Code 072 LLMs on domain-specific service 073 robot applications (due to their cost-074 effectiveness, better privacy protec-075 tion, and customizability). However, 076 open-weight LLMs are still prone 077 to errors. As a result, using SELF-INSTRUCT naively can produce low-079 quality data, such as programs that violate domain-specific constraints or 081 instructions that are infeasible for the robot to execute. For instance, as

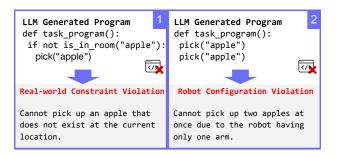

Figure 2: Examples of programs violating domain-specific constraints.

083 shown in the figure Fig. 2, the program may attempt to pick up an apple that is not present in the current location (example 1); or the instruction might ask the robot to pick up multiple objects 084 simultaneously, which is physically impossible (example 2). To catch these errors, executing the 085 program in a simulator with well-defined environments may appear promising. However, such envi-086 ronments require pre-enumeration of relevant entities and their states, which can result in rejecting a 087 vast number of programs generated by SELF-INSTRUCT even if they are executable, simply because 880 the pre-defined simulation environment fails to capture certain relevant aspects (e.g., the presence of 089 an "apple"); this undermines the diversity of the data generated. 090

This work introduces ROBO-INSTRUCT to bring the best of both worlds — it preserves the diversity 091 of programs generated by an LLM while providing the correctness of simulator-based checking. 092 ROBO-INSTRUCT is a new framework based on SELF-INSTRUCT, to address the challenges posed 093 by using an open-weight LLM for generating domain-specific robot programs. As shown in Fig. 1, 094 ROBO-INSTRUCT introduces two novel components: (1) ROBOSIM, a task-agnostic simulator that 095 encodes domain-specific constraints and validates robot programs generated from SELF-INSTRUCT. 096 Critically, ROBOSIM dynamically synthesizes consistent simulation environments starting from arbi-097 trary programs. (2) INSTALIGN, an LLM-aided instruction-program alignment procedure that revises 098 the generated instructions to better reflect the intent of the generated programs. ROBO-INSTRUCT 099 also uses a rejection-sampling mechanism to discard invalid programs detected by ROBOSIM and query SELF-INSTRUCT for a new program based on the same instruction. 100

We use an 8B Llama3 model (AI, 2024) to generate instruction-program training data and fine-tune a
7B CodeLlama model (Rozière et al., 2024) on ROBOEVAL, a domain-specific benchmark for service
robot programs. Our ROBO-INSTRUCT-fine-tuned model significantly outperforms the base model by
28.75% in pass@1 scores and achieves a 13.75% improvement over its SELF-INSTRUCT-fine-tuned
variant. Moreover, it surpasses several larger code models, including Deepseek-Coder-33B (Guo
et al., 2024), Starcoder2-15B (Lozhkov et al., 2024), GPT-3.5-Turbo (OpenAI, 2022), and Gemini-

107 Pro (Team et al., 2024). Finally, in real-world deployment, we demonstrate that ROBO-INSTRUCT achieves significantly lower latency compared with GPT-3.5 and GPT-4.

108	Contributions Our main contributions are as follows
109	1. We introduce ROBO-INSTRUCT, a new framework for improving open-weight LLMs'
110	ability to generate training data for finetuning Code LLMs on domain-specific service robot
111	applications. This framework introduces two novel components, ROBOSIM and INSTALIGN.
112	2. We present ROBOSIM, a method to synthesize consistent simulation environments dynami-
113	<i>cally</i> for verifying the generated programs. This method preserves the diversity of programs
114	generated by an LLM while providing correctness with simulator-based checking.
115	3. We present INSTALIGN, a simple <i>instruction-program alignment procedure</i> that revises
116 117	generated instructions better to reflect the actual results of the generated program.
118	4. We show that the ROBO-INSTRUCT finetuned model can significantly outperform the original
119	base model and its finetuned variant using SELF-INSTRUCT in generating domain-specific
120	service robot programs. It also surpasses several other larger Code LLMs.
121	
122	2 ROBO-INSTRUCT
123	
124	In this section, we describe how ROBO-INSTRUCT generates training datasets for domain-specific
125	service robot programs. Fig. 1 provides a high-level overview of the framework. To add an entry to
126	the training dataset, SELF-INSTRUCT first generates an instruction-program pair based on robot APIs
127	and seed tasks (detailed prompts in Appendix A.4.2). Then, ROBOSIM dynamically synthesizes a consistent simulation environment to validate the program as it executes.
128	
129	If the program is invalid, ROBO-INSTRUCT applies a rejection-sampling method, which generates
130	a new program based on the same instruction and re-evaluates it. This process continues until the program is valid or a predefined maximum resampling limit is reached. If the limit is exceeded, the
131	instruction may be incompatible with the domain-specific APIs or too complex, so the instruction-
132 133	program pair is discarded.
134	Finally, if the program is valid, INSTALIGN uses an open-weight LLM to refine the instruction to
135	better align with the program's intent, and the revised instruction-program pair is added to the training
136	dataset. In the following subsections, we delve into the specific design of each component.
137	
138	2.1 ROBOSIM: DYNAMIC SYNTHESIS OF SIMULATION ENVIRONMENTS FOR PROGRAM
139	VALIDATION
140	
141	We present a principled approach to designing ROBOSIM, a system for dynamically synthesizing consistent simulation environments to validate domain-specific robot programs. For service mobile
142	robots, a simulation environment often relies on three concepts:
143	rootis, a simulation en moniment orten renes on ance concepts.
144	1. A list of <i>entities</i> to reason about, e.g., "apple", "kitchen"
145 146	2. The <i>type</i> of the entities, and hence their affordances, e.g., "apple" is an object, you can pick
147	it up; "kitchen" is a location, you can go to it, and it contains objects.
148	3. The <i>state</i> of the entities in the world, e.g., the "apple" is in the "kitchen".
149	
150	These concepts are closely related to the domain-specific APIs, where each API invocation during
151	program execution can trigger updates to the simulation environment. To handle the interaction
152	between APIs and simulation environments, we introduce DYNAMICEVAL, an algorithm inspired by Angelic Execution (Broy & Wirsing, 1981), a software engineering technique to infer program
153	properties from incomplete API specifications. DYNAMICEVAL automatically generates a simulation
154	environment for each program and checks its correctness within the inferred environment.
155	As shown in Alg. 1, upon each API invocation, the corresponding inputs and the current simulation
156	environment are passed into DYNAMICEVAL. DYNAMICEVAL first infers relevant entities when
157 158	they appear in the program being checked (line 5). For instance, if a program includes the statement
150	pick("apple"), DYNAMICEVAL infers that apple is an entity to consider, even if it is not currently
160	defined in the simulation environment.

For each relevant entity, if it has already been initialized (line 7), DYNAMICEVAL infers its type and new state from the API invocation and checks for any inconsistencies with the current simulation

1:	Input: api_fn	▷ The API function name
2:	Input: api_inputs	> The input received by the API invocation
3:	Input: \mathcal{W}	The current simulation environment
	$info \leftarrow Extract_API_INVOCATION_INFO(api_fn, api_input$	s)
5:	entities \leftarrow INFER_RELEVANT_ENTITIES(info)	
6:	for entity \in entities do	
7:	if Is_ENTITY_INITIALIZED(entity, W) then	
8:	entity_type \leftarrow DEDUCE_TYPE(info)	
9:	entity_new_state \leftarrow DEDUCE_STATE(info)	
10:	if CHECK_TYPE_CONSISTENCY(entity, entity_type, info	(\mathcal{W}) and \setminus
	CHECK_STATE_CONSISTENCY(entity, entity_new_sta	te, info, \mathcal{W}) then
11:	UPDATE_ENTITY_STATE(entity, info, W)	
12:	else	
13:	raise "Error: state inconsistent or type mismatch"	
14:	end if	
15:	else	
16:	INITIALIZE_ENTITY_WITH_RANDOM_STATE(entity, in	fo, W)
17:	end if	
18:	end for	
19:	retval \leftarrow GET_RETURN_VALUE(info, W)	
20.	return retval	

185

186

187 1

188 2

189 ³ go_to("apple")

type 1 . If a program contains:

def task program():

pick("apple")

190 191

192

193

By invoking API calls sequentially, DYNAMICEVAL first infers that "apple" is an object and then raises an error when go_to("apple") is called. If no inconsistency is detected, the simulation environment is updated accordingly based on the API definition (line 11).

On the other hand, if the entity has not been initialized, it will be assigned a random plausible state (line 16). For example, the API is_in_room(object) checks if an object is in the same location as the robot and expects a boolean return. In this case, DYNAMICEVAL assigns a 50% probability for the apple to be in the robot's current location — determining the state of the apple as either present or absent in the robot's location.

Finally, DYNAMICEVAL computes and returns the value based on the API specification and the updated simulation environment. Fig. 3 illustrates how ROBOSIM leverages DYNAMICEVAL to dynamically synthesize the simulation environment and validate the program. In ROBOSIM, the simulation starts with only the robot at its initial position, and entities are added as the program runs. At execution timestep 2a, after the robot picks up an apple, it becomes unclear whether another apple remains at the location. Therefore, DYNAMICEVAL sets the apple's state to "Undefined" and removes it in subsequent executions. This method is also related to STRIPS planning, as we demonstrate the connection in Appendix A.2.

In the example program shown in Fig. 3, it's clear to humans that the program's logic is flawed because it attempts to pick up the apple, which is not present in the room. But *how would the simulator identify this as a failing state*? ROBOSIM solves this issue by simulating all possible states of the discovered entities and verifying that none lead to erroneous program execution. In this case, the "apple" can either be present in the room or not. If the apple is not present, executing pick("apple") will result in an error. Checking all possible states requires exploring an exponentially growing number of combinations based on the entities discovered. To manage this, ROBOSIM

¹In this example, type compatibility check is strict (i.e., "apple" is only an object and no further inference is made about its location). Nevertheless, the algorithm is also capable of handling more advanced scenarios.

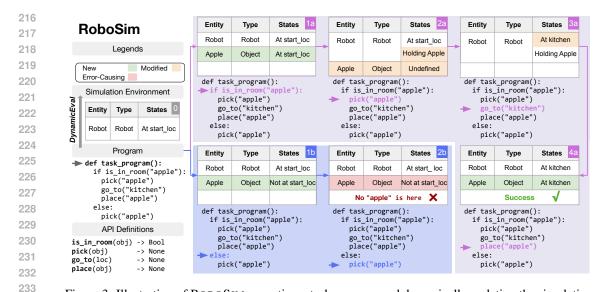

Figure 3: Illustration of ROBOSIM executing a task program and dynamically updating the simulation 234 environment. Initially, the environment only contains the robot's starting location. As the program 235 runs, two possible execution paths emerge (purple and blue). The environment is updated by 236 DYNAMICEVAL at each step, reflecting the robot's actions, object states, and location changes along 237 both paths.

238 239 240

241 242 employs a bounded compute budget to randomly sample from this exponential space, as detailed in the overall ROBOSIM algorithm in Alg. 2.

Algorithm 2 ROB	${ m M}({\mathcal P})$

258

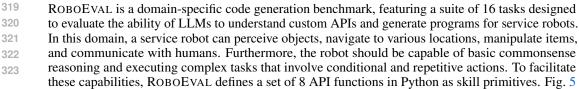

2.2 INSTALIGN: LLM-AIDED INSTRUCTION-PROGRAM ALIGNMENT PROCEDURE

Even after ROBOSIM verifies that a program doesn't violate domain-specific constraints, it may still 259 have subtle inconsistencies with the instructions — such as omitting a step implied by the instruction. 260 The proposed rejection-sampling strategy alone cannot resolve this issue, and correcting verified 261 programs to fully reflect the instructions while ensuring they remain valid is a challenging task. 262

We note that LLMs nowadays have demonstrated impressive code understanding capabilities (Rozière 263 et al., 2024; Nam et al., 2024; Leinonen et al., 2023; Li et al., 2023; Lekshmi-Narayanan et al., 2024). 264 Instead of correcting the program, it may be more effective for the LLM to revise its generated 265 instructions to better align with the program's intent. 266

We propose INSTALIGN, a procedure that prompts an LLM to revise generated instructions to better 267 match the intent of the program, as shown in Fig. 4. INSTALIGN follows two steps: first, it uses 268 Chain-of-Thought reasoning (CoT) (Wei et al., 2022) to generate a revised instruction based on the 269 instruction-program pair; then, it prompts the LLM to compare the original and revised instructions,

324 illustrates these function signatures and definitions, alongside an example task instruction and its 325 canonical solution from the benchmark. In addition, unlike other popular code generation benchmark 326 tasks (Chen et al., 2021; Austin et al., 2021; Li et al., 2022; Liu et al., 2023b; Lai et al., 2022; 327 Hendrycks et al., 2021), the order of the robot's actions is crucial for successfully completing the 328 specified tasks. For instance, in the task "bring me a marker from the classroom that does not have a whiteboard," the robot must check each classroom until it finds one without a whiteboard, whereas 329 simply bringing back a marker is insufficient. Hence, ROBOEVAL evaluates the generated program by 330 executing it in a simulator to capture the action traces, which are subsequently validated for sequence 331 correctness using temporal logic. 332

3.2 RQ1: IS ROBO-INSTRUCT EFFECTIVE AT GENERATING TRAINING DATA TO FINE-TUNE A SMALL LANGUAGE MODEL FOR GENERATING DOMAIN-SPECIFIC ROBOT PROGRAMS?

Table 1: Pass@1 results of different LLMs on ROBOEVAL computed with greedy decoding T = 0 and nucleus sampling T = 0.2.

356 Experiment Setup. We use the open-weight LLM, Llama3-8B-Inst, for ROBO-INSTRUCT. To 357 generate a diverse dataset, we employ nucleus sampling for creating instruction-program pairs, 358 setting the temperature T = 1 and top p = 0.95. The maximum resampling limit is capped at 3 to 359 accommodate instructions that initially produce invalid programs. For the LLM used in INSTALIGN, 360 we empirically adjust the generation temperature to T = 0.3 to optimize performance. Furthermore, 361 we assess the edit similarity between token sequences of each instruction pair in the dataset (Lee 362 et al., 2022), removing duplicates where the similarity score exceeds 0.6. The same similarity-363 based approach is used to decontaminate the dataset against the ROBOEVAL benchmark tasks. We use the same setup to generate data via SELF-INSTRUCT. Instead of discarding invalid programs, 364 SELF-INSTRUCT includes every generated instruction-program pair in the training dataset. Finally, we create two datasets with 5K instruction-program pairs each using SELF-INSTRUCT and ROBO-366 INSTRUCT respectively. These datasets are then used to fine-tune the CodeLlama-Python-7B model. 367 The learning rate is set to be 3e-5 with a warmup ratio of 3% and a constant lr scheduler. We employ 368 the AdamW optimizer (Loshchilov & Hutter, 2019) with an effective batch size of 8, training each 369 model for 5 epochs using a sequence length of 2048 tokens. We train all our models on a single 370 H-100 GPU using unsloth (Unslothai, 2024). 371

Baselines. We divide our baseline models into 2 categories: 1) proprietary LLMs, including
GPT4 (OpenAI et al., 2024), GPT3.5-Turbo (OpenAI, 2022), Gemini-Pro (Team et al., 2024),
and 2) open-weight LLMs, including Codellama-Python-7B (Rozière et al., 2024), CodellamaPython-34B, Starcoder2-33B (Lozhkov et al., 2024), Deepseek-Coder-33B (Guo et al., 2024), and
Llama3-8B-Inst (AI, 2024).

Tab. 1 presents the average pass@1 results for different LLMs on ROBOEVAL, using two settings: greedy decoding at temperature T = 0 and nucleus sampling at temperature T = 0.2. The results

378 show that ROBO-INSTRUCT-fine-tuned CodeLlama significantly improves upon the base CodeLlama-379 Python-7B, and outperforms the SELF-INSTRUCT-fine-tuned variant (Appendix A.3.3 shows that 380 improvements over SELF-INSTRUCT are not the result of distributional biases in the selection 381 process). Notably, ROBO-INSTRUCT surpasses all open-weight models, including larger ones like 382 CodeLlama-Python-34B and Deepseek-Coder-33B. Additionally, although the training dataset was generated using Llama3-8B-Inst, which scores less than 50% pass@1 on ROBOEVAL from Tab. 1, 383 our ROBO-INSTRUCT-fine-tuned model still achieves a significant improvement, scoring 68.75%. 384 Finally, compared to proprietary models, while our ROBO-INSTRUCT-fine-tuned model trails the 385 more powerful GPT-4, it outperforms GPT-3.5-Turbo and Gemini-Pro in generating programs for 386 service mobile robots. This result demonstrates the effectiveness of our approach in generating 387 domain-specific robot program data for fine-tuning a much smaller language model. It suggests 388 that the fine-tuned model could potentially replace some proprietary models, providing a more 389 cost-effective and private option for local deployment. 390

3.3 RQ2: How Do RoboSim and InstAlign Impact the Effectiveness of Robo-Instruct?

	Т	=0	T=	0.2	Invalid
Method	pass@1	Improv.	pass@1	Improv.	Programs
Codellama-7B-Python	40.00%	+0%	39.31%	+0%	38.31%
Self-Instruct	55.00%	+15.00%	52.69%	+13.38%	20.94%
+Reject Unsolvable (RU)	60.00%	+20.00%	57.62%	+18.31%	23.38%
+ROBOSIM + RU	63.75%	+23.75%	63.88%	+24.57%	14.13%

407

391

392

393 394

397

408 Using the same setup as in the previous section, we investigate the effectiveness of ROBOSIM 409 and INSTALIGN. Since SELF-INSTRUCT may generate instructions for which no corresponding 410 valid program can pass in ROBOSIM, we include Reject Unsolvable (RU) as an additional baseline. SELF-INSTRUCT+RU discards instructions for which no valid programs were found to successfully 411 execute in ROBOSIM, and preserves instructions for which at least one passing program was found. 412 Tab. 2 shows the average pass@1 results from CodeLlama-7B-Python fine-tuned on different datasets 413 generated by each method. First, results from SELF-INSTRUCT + RU indicate that simply discarding 414 invalid instructions improves model performance. Additionally, fine-tuning with a dataset created 415 from SELF-INSTRUCT + ROBOSIM results in the smallest proportion of invalid program errors. 416 Finally, incorporating either ROBOSIM or INSTALIGN individually offers improvements over the 417 baseline SELF-INSTRUCT + RU results, incorporating both in ROBO-INSTRUCT results in the best 418 pass@1 performance. We refer the readers to Appendix A.1 for more results.

419 420 421

3.4 QUALITATIVE ANALYSIS OF THE GENERATED PROGRAM ERRORS

422 We qualitatively analyze invalid programs identified by ROBOSIM, as shown in Fig. 6. The first three 423 examples are easily recognizable to humans as flawed. However, the last example is more complex 424 and involves an error when the robot can navigate to more than two rooms. After the robot places a 425 toy in the living room, DYNAMICEVAL updates the environment to reflect that a toy is now in the 426 room (line 8). However, when the robot returns to the living room later (line 6), it will not drop the 427 item it's holding (line 8). As a result, when the robot enters a third room (line 4) and tries to pick up another toy (line 5), an error will occur because the robot is only capable of carrying one item at a 428 time. This example demonstrates that ROBOSIM can detect invalid programs beyond those easily 429 identifiable through human inspection. 430

²Programs have been adapted to succinctly demonstrate the types of errors and fit within the figure.

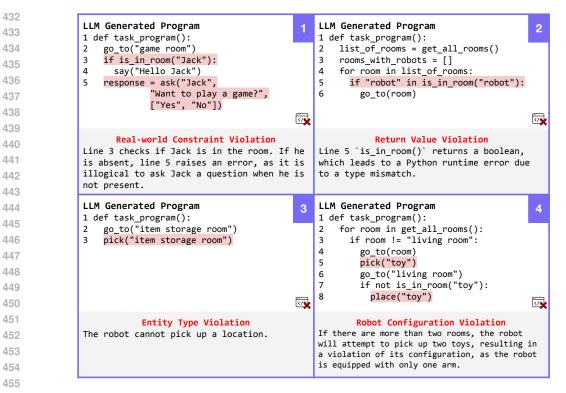

Figure 6: SELF-INSTRUCT-Generated Program Errors. Examples highlight errors that violate domainspecific constraints.²

4 REAL-WORLD DEPLOYMENT RESULTS

We deployed the ROBO-INSTRUCT fine-tuned model to generate and execute mobile robot programs in the real world, as shown in Fig. 7. Compared to GPT-4 and GPT-3.5-turbo (Tab. 3), our model generates programs about 6x faster than GPT-4 and 3x faster than GPT-3.5-turbo, with similar output quality. In Appendix A.5 we showcase more results on long-horizon tasks beyond ROBOEVAL.

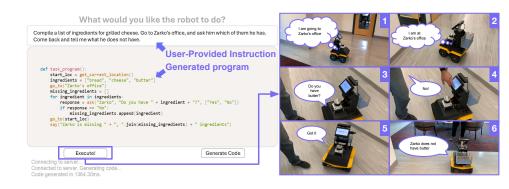

Figure 7: Deployment of the ROBO-INSTRUCT fine-tuned model to generate programs based on user-provided instructions and execute them on the robot.

Models	GPT-4	GPT-3.5-Turbo	Robo-Instruct (Ours)
Inference Speed	19 tokens/s	42 tokens/s	114 tokens/s

486 5 RELATED WORK

488 5.1 LLMs for Robot Code Generation

490 LLMs have shown impressive capabilities in generating robot programs from natural language (Liang et al., 2022; Singh et al., 2023; Huang et al., 2023a). One popular approach uses LLMs to generate 491 composable costmaps for robots to plan their motion on. In this approach, Voxposer (Huang et al., 492 2023b) focuses on the tabletop manipulation setting and NavCon (Biggie et al., 2023) focuses on 493 creating composable maps for navigation. Using LLM to create reward functions is also promising. 494 Eureka (Ma et al., 2023; 2024) and Language to Rewards for Robotic Skill Synthesis (Yu et al., 2023) 495 both show that LLM can generate good reward functions that allows robots to acquire complex skills. 496 Finally, LLM can also be used to generate programs for high-level planning. LLM+p (Liu et al., 497 2023a) outputs a robot plan in the form of the well-defined planning domain definition language 498 (PDDL). Tidybot (Wu et al., 2023) uses an LLM to generate a rule that captures user preferences 499 from examples and executes a program to sequentially complete the task in order. RoboEval (Hu 500 et al., 2024) focuses on generating domain-specific programs for service mobile robots. It generates a program that allows the service robot to carry out long-horizon tasks and then validates the correctness 501 of the program. 502

503 5.2 GENERATING DATASETS FOR FINE-TUNING LLMS

To enhance LLMs' performance in code generation, numerous studies have explored the creation of 505 specialized datasets (Muennighoff et al., 2024; Köpf et al., 2023; Muennighoff et al., 2022). SELF-506 INSTRUCT (Wang et al., 2022) is one popular method for generating synthetic datasets using an LLM. 507 Following this methodology, Alpaca (Taori et al., 2023) generates 52K instruction-following demon-508 strations and subsequently fine-tunes the LLaMA 7B model (Touvron et al., 2023) to create Alpaca 509 7B, which can behave qualitatively similarly to OpenAI's text-davinci-003. Code Alpaca (Chaudhary, 510 2023) extends this approach to generate code instructions using 21 seed tasks, while Gorilla-LM (Patil 511 et al., 2023) adapts the method to focus on ML domain-specific APIs from Huggingface, TensorFlow 512 Hub, and Torch Hub. To create more complex instructions, Evol-Instruct (Xu et al., 2024; Luo 513 et al., 2024) proposes iteratively updating instructions to become more complex through different 514 prompting strategies. In addition to Evol-Instruct, OSS-Instruct (Wei et al., 2023) uses open-source 515 code snippets to generate 75K high-quality instruction data and fine-tunes the CodeLlama-Python-7B model to create Magicoder, which can match the performance of GPT-3.5-Turbo (OpenAI, 2022) on 516 HumanEval (Chen et al., 2021). While these works focus on creating seed instruction sets to generate 517 synthetic data to effectively fine-tune an LLM, our research investigates post-processing methods in 518 addition to SELF-INSTRUCT. Specifically, we concentrate on generating domain-specific programs 519 in robotics (Hu et al., 2024), where we can effectively leverage constraints to filter out erroneous 520 programs. 521

522 523

6 CONCLUSION, LIMITATION AND FUTURE WORKS

- In this work, we introduce ROBO-INSTRUCT, a novel framework to generate synthetic training 524 data to fine-tune small language models for domain-specific robot programs. ROBO-INSTRUCT 525 comprises two novel components: 1) ROBOSIM, a method to synthesize consistent simulation 526 environments dynamically for verifying the generated programs, and 2) INSTALIGN, an LLM-aided 527 instruction alignment procedure to revise instructions to better align with the generated programs. 528 The experimental results show that the 7B CodeLlama model fine-tuned on the ROBO-INSTRUCT 529 dataset significantly outperforms larger open-weight LLMs and proprietary models like GPT-3.5-530 Turbo and Gemini-Pro in generating service robot programs. However, a key limitation is that 531 ROBO-INSTRUCT relies on SELF-INSTRUCT to filter invalid programs, which may introduce biases 532 and affect dataset quality. Another limitation is the use of a simple rejection-sampling method to 533 handle invalid programs, which may not fully address the underlying issues. Future work will focus 534 on improving dataset quality by integrating ROBO-INSTRUCT with advanced methods like Evol-Inst 535 and OSS-Inst.

756 A APPENDIX

758 A.1 OVERVIEW

760 In this appendix, we first outline the relationship between DYNAMICEVAL and the classic STRIPS planning formulation in subsection A.2, providing a new perspective on the proposed algorithm. 761 In subsection A.3, we present additional ablation experiments to analyze the percentage of invalid 762 programs generated by SELF-INSTRUCT and the effectiveness of the rejection-sampling strategy combined with ROBOSIM. We also explore how the generation temperature in INSTALIGN impacts 764 final performance and compare the dataset diversity produced by ROBO-INSTRUCT and SELF-765 INSTRUCT. Subsection A.4 lists the seed tasks used in ROBOEVAL and the CoT prompts. in 766 subsection A.5, we report real-world experiments that empirically evaluate the performance of our 767 fine-tuned model on two long-horizon tasks, which differ significantly from those in ROBOEVAL, 768 and assess the model's latency in generating programs. Although this work focuses on service 769 mobile robots, the proposed framework is adaptable to other domains. In subsection A.6, we offer 770 toy examples showing how DYNAMICEVAL can be extended to verify programs by incorporating 771 domain-specific constraints.

- 772
- 773 A.2 RELEVANCE TO STRIPS PLANNING 774

The proposed DYNAMICEVAL shares significant similarities with the formulation of STRIPS planning. A STRIPS instance is typically represented as a tuple $\langle I, G, A, P \rangle$, where *I* denotes the initial state of the simulation environment, *G* represents the desired goal state that the robot aims to achieve, *A* defines the set of actions available to transition between states, and *P* is the set of preconditions that must be satisfied before performing actions. Thus, DYNAMICEVAL can be reformulated to align with the STRIPS formulation as shown in Alg. 3. Each API invocation corresponds to an action, and its precondition consists of a set of literals, representing specific combinations of entities, types, and states.

To address this, we extend the classic STRIPS formulation by incorporating dynamically discovered 783 literals. Unlike the conventional STRIPS approach, where each literal is binary—True when defined 784 and False when not-we introduce a third value, "Undefined." This means a literal must be explicitly 785 defined as either True or False; otherwise, it remains in the Undefined state. When an action requires 786 a literal that is undefined, a random value (True or False) is assigned to it, and the literal is added to 787 the state of the simulation environment (line 7). Once the precondition is fully defined, the action is 788 executed, and domain-specific constraints are checked for any violations (line 10). This extension 789 enables DYNAMICEVAL to handle arbitrary programs effectively. 790

1: Input: api_fn	▷ The API function nation
2: Input: api_inputs	The input received by the API invocation
3: Input: W	The current state of the simulation environm
4: $p \leftarrow \text{GETPRECOND}(\text{api}_fn, \text{params})$	▷ Get the parameter-specific precondition for api
5: for $l \in p$ do	Loop through every literal in the precondit
6: if CHECKDEFINED (W, l) is Undefined then	1
7: $W \leftarrow \text{GROWWORLD}(l, \mathcal{W})$	> Randonly instantiate the literal and grow \mathcal{W} to includ
8: end if	
9: end for	
10: retval, $\mathcal{W} \leftarrow \text{EXECUPDATE}(\text{api}_fn, \text{params}, \mathcal{W})$	→ Execute api_fn and update
11: return retval

804 805

806

A.3 ABLATION EXMPERIMENTS

A.3.1 THE EFFECTIVENESS OF THE REJECTION-SAMPLING STRATEGY

We analyze the percentage of instruction-program pairs discarded by ROBOSIM at various maximum resampling limits, as shown in Fig. 8. Initially, with the maximum resampling limit set to 0, disabling the rejection-sampling method, approximately 51% of the programs generated by SELF-INSTRUCT contain errors. As the limit increases, fewer programs are discarded. However, there is a diminishing

return; even with the maximum resampling limit set to 10, about 15% of the instructions still result in invalid programs.

A.3.2 INSTRUCTION ALIGNMENT MODEL TEMPERATURE

We further investigate how varying LLM temperatures for generating the revised instruction in INSTALIGN impact the performance of the fine-tuned model. Fig. 8 shows the bar chart of the pass@1 score of the models fine-tuned over datasets generated using different LLM temperatures in INSTALIGN. The model performs the best when fine-tuned on the dataset generated using LLM temperature T = 0.3. As the temperature increases, we observe a decrease in performance.

A.3.3 ANALYSIS OF GENERATED DATASET

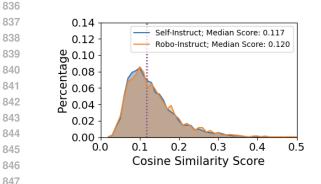

Figure 9: Cosine similarities between ROBOEVAL and generated data.

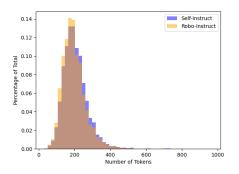

Figure 10: Token length distribution for each instruction-program pair.

Similar to Magicoder (Wei et al., 2023), we show the improvements from ROBO-INSTRUCT are not merely due to selection bias, i.e., including data more aligned with the distribution of ROBOEVAL tasks than SELF-INSTRUCT. We pair each sample from the generated dataset with task instructions and their canonical solutions, then compute cosine similarity using TF-IDF embeddings (Sparck Jones, 1988). Fig. 9 shows comparable token similarities between both methods. Additionally, Fig. 10 presents the token length distribution, which also appears similar for both.

Method	Size	Ngram=4 Score	# Synth. Loc.	# Synth. Obj.
SELF-INSTRUCT	5K	0.581	956	1060
ROBO-INSTRUCT	5K	0.587	1025	928

Table 4:	Dataset	Statistics
----------	---------	-------------------

863 Since ROBOSIM does not rely on pre-defined simulation environments, we aim to assess the diversity of programs generated by SELF-INSTRUCT and whether ROBO-INSTRUCT can maintain this diversity.

864 To do so, we measure the number of distinct entities, such as synthetic locations and objects. As shown 865 in Tab. 4, with a dataset of only 5,000 samples, approximately 1,000 unique objects and locations 866 are generated, highlighting that conventional robot simulations with pre-defined environments are 867 insufficient. Additionally, Tab. 4 presents the n-gram diversity scores for each dataset, indicating that 868 both distributions and dataset statistics are highly similar. This suggests that ROBO-INSTRUCT not 869 only preserves but enhances the quality of generated data compared to SELF-INSTRUCT, rather than simply aligning the dataset with benchmark tasks. 870

A.4.1 ROBOEVAL SEED TASK EXAMPLE

Seed Task Example 1:

```
# Instruction: Go to Arjun's office, ask him if he is ready to head out,
   1
      # and come back and tell me what he said
   2
      def task_program():
   3
880
           start_loc = get_current_location()
   4
881 5
           go_to("Arjun's office")
882 6
           response = ask("Arjun",
               "Are you ready to go?",
883 7
               ["Yes", "No"])
884
           go_to(start_loc)
   9
           say("Arjun said: " + response)
   10
```

Seed Task Example 2:

```
890
       # Instruction: Ask Alice if she needs 1, 2, or 3 boxes.
891
       # Go to the storage room and ask if they have that many boxes.
    2
892 3
       # If so, go place the boxes in Alice's office.
       # Otherwise, tell Alice you could not get the boxes.
893 4
       def task_program():
   5
894
    6
           go_to("Alice's office")

       ### Role
1009 <sub>2</sub>
       You are an expert at understanding robot programs.
1010 3
       You will be given a task instruction and robot program pair.
       However, the instruction may not align with the program well.
1011 4
       You need to correct the task instruction to match the given robot program.
1012 <sup>5</sup>
1013 <sup>6</sup><sub>7</sub>
       ### Context
1014 8 The robot only has access to the following 8 APIs and
10159 standard Python functions
       - def get_current_location() -> str:
101610
1017<sup>11</sup>
       - def get_all_rooms() -> list[str]:
1018<sup>12</sup><sub>13</sub>
       - def is_in_room(object : str) -> bool:
       - def go_to(location : str) -> None:
101914 - ask(person : str, question : str, options: list[str]) -> str:
102015 - say(message : str) -> None:
102116
      - def pick(obj: str) -> None:
       - def place(obj: str) -> None:
1022<sup>17</sup>
1023<sup>18</sup>
19
    18
       ### Inputs
1024<sub>20</sub>
       Original Instruction
102521
            This is a task instruction that may not align with the robot program
   22 Robot Program
```

1026 ____23 This is a python function starting with `def task_program():` 1027₂₄ 1028₂₅ ### Task 102926 1. Write down all the provided APIs used in the program and explain the effect of each API in this program 1030²⁷ 1031²⁸ 2. Examine these APIs and write down step by step what the program does 3. Combine all the results above and rewrite the instruction 29 1032₃₀ You need to be specific and clear in your final corrected instruction. 1033

1036

1035 A.5 REAL-WORLD EXPERIMENTS

1037 A.5.1 PROGRAM GENERATION RESULTS BEYOND ROBOEVAL

1038 We conducted a small qualitative experiment to assess the performance of the base model, SELF-1039 INSTRUCT fine-tuned models, ROBO-INSTRUCT fine-tuned models, and GPT-4 on long-horizon tasks. 1040 To showcase performance, we created two new long-horizon tasks that differ significantly from those 1041 in the ROBOEVAL benchmark. Using a temperature setting of 0, we generated programs with each 1042 model and found that our ROBO-INSTRUCT fine-tuned model successfully produced correct programs, 1043 while both the base model and SELF-INSTRUCT fine-tuned model failed. Additionally, GPT-4 made an error on the second instruction. We show the generation results from ROBO-INSTRUCT fine-tuned 1044 models and GPT-4 below. 1045

- 1046 Task instruction 1:
- 1047 1048

1055

```
10491 Let's play a game: Double and give it to the next person. Start with
10502 1 dollar. Go to rooms A, B, C, D, E, F, and G. If you see someone, tell
them how much money you have. Then ask if they would like to take the
money now or double the amount and give it to the next person. If they
10525 choose to take it, the game is over, and you should come back to me.
10536 Otherwise, double your money and continue. If, in the end, no one takes
10547 the money, tell me how much you still have.
```

1296 A.6.2 AI-POWERED PERSONAL DIGITAL ASSISTANT

Consider a broader application than robotics: code generation for an AI-powered personal digital assistant. This AI assistant could handle scheduling events using an API function like schedularon_calendar(event, start_time, duration). Given the instruction: "My schedule is free tomorrow morning. Please create two 1-hour timeslots for office hours for my robotics and deep learning class." The assistant could generate a program to create these timeslots:

1306 3

1307 ⁴

1308 ⁵

1304 ₁	def	task_p	rogran	n ():
1305 ₂		schedu		

```
schedule_on_calendar("robotics class office hour",
                     "9:30 am", "1 hr")
schedule_on_calendar("deep learning class office hour",
                    "10:00 am", "1 hr")
```

In this example, DYNAMICEVAL needs to reason about the entities "robotics class office hour" and "deep learning class office hour", which are categorized as event types. The event type indicates that these entities have associated timeslots. The state of these entities is defined by the time they occur: robotics class office hour is set for 9:30-10:30 am, and deep learning class office hour is set for 10:00-11:00 am. During evaluation, DYNAMICEVAL can identify a time conflict between these two office hours and thus determine that the generated program is invalid.
