# VITS-Based Data Augmentation for Improved ASR Performance and Domain Adaptation

Anonymous EMNLP submission

#### Abstract

 Although significant advancements have been made in end-to-end speech recognition, it still remains a challenging task when dealing with low-resource scenarios, even with the utiliza-005 tion of traditional data augmentation methods. Recent technological progress, demonstrated by the success of VITS and its variations, has spurred interest in exploring Text-to-Speech (TTS) synthesis for data augmentation to ad- dress the aforementioned difficulties. In this study, we investigate the effectiveness of in- tegrating synthetic speech generated by VITS into the train sets of ASR systems. Through comprehensive experiments, we assess the im- pact of this approach on improving the general- ization and performance of ASR models in En- glish, Mandarin, and Japanese. Experimental results indicate that the average character-level accuracy of the VITS-based data augmentation method matches the best performance observed among traditional data augmentation methods before model transfer. After model transfer, the average character-level accuracy of the VITS- based data augmentation method significantly outperforms all traditional methods, surpassing Speed Perturbation, the best-performing tradi- tional method, by 3.5%, as well as Tacotron2 and Fastspeech. Our findings indicate that models trained with the VITS-based data aug- mentation method exhibit enhanced resilience towards domain shift challenges, demonstrat- ing improved adaptability across varied linguis- tic contexts, thus highlighting the potential of VITS as a valuable data augmentation tech-**035** nique.

## **036** 1 Introduction

 Automatic Speech Recognition (ASR) tasks play a critical role in enabling human-computer interac- tion, information retrieval, and the advancement of speech-based applications across diverse do- mains. The performance of ASR models relies heavily on the quality and quantity of training

data. With an ample supply of high-quality train- **043** ing data, both hybrid models (integrating deep neu- **044** ral networks with Hidden Markov models (DNN- **045** HMM)) and end-to-end models (jointly trained neu- **046** ral network systems) demonstrate nearly equiva- **047** lent performance [\(Lüscher et al.,](#page-8-0) [2019\)](#page-8-0). However, **048** acquiring large amounts of high-quality labeled **049** speech data tends to be time-consuming and costly. **050** This challenge, particularly pronounced for low- **051** resource languages or specific domains, exacer- **052** bates the difficulty of achieving high performance **053** in low-resource tasks, where end-to-end models, **054** compared to hybrid models, notably lag behind **055** [\(Medennikov et al.,](#page-8-1) [2020\)](#page-8-1). Moreover, trained ASR **056** models often encounter domain shift when trans- **057** [f](#page-8-3)erred to other datasets[\(Fan et al.,](#page-8-2) [2022;](#page-8-2) [Hiday-](#page-8-3) **058** [aturrahman et al.,](#page-8-3) [2023;](#page-8-3) [Chakrabarty et al.,](#page-8-4) [2023\)](#page-8-4). **059** Domain shift occurs when the distribution of data **060** in the target domain, where the model is deployed, **061** differs significantly from that in the source domain, **062** where the model is trained. This difference can  $063$ lead to a significant decrease in model performance. **064** Addressing domain shift is therefore crucial for en- **065** suring the robustness and generalization ability of 066 machine learning models across diverse and evolv- **067** ing scenarios. **068**

Data augmentation, as an effective method to en- **069** hance the diversity of training data through various **070** transformations and expansions, has been widely **071** applied in fields such as computer vision and natu- **072** [r](#page-8-5)al language processing [\(Pradana et al.,](#page-9-0) [2023;](#page-9-0) [Joshi](#page-8-5) **073** [et al.,](#page-8-5) [2023;](#page-8-5) [Muthumari et al.,](#page-8-6) [2022\)](#page-8-6). In ASR, data **074** augmentation can not only alleviate the problem of **075** insufficient data but also enhance the robustness of **076** the model, especially in coping with different noise **077** environments and speaker variations. Moreover, **078** data augmentation methods can mitigate the per- **079** formance degradation of models caused by domain **080** shift to some extent. 081

Common speech data augmentation methods in- **082** clude Noise Augmentation [\(Ko et al.,](#page-8-7) [2015\)](#page-8-7), Vol- **083**  ume Augmentation, Speed Perturbation [\(Ko et al.,](#page-8-7) [2015\)](#page-8-7), and Specaugment [\(Park et al.,](#page-8-8) [2019\)](#page-8-8) which involves time and frequency domain masking. Nev- ertheless, traditional data augmentation methods have limitations, such as being unable to generate entirely new speech patterns and linguistic vari- ations. They rely on manipulating existing au- dio, which may not fully capture the diversity and complexity of natural speech. In contrast, Text-to- Speech (TTS) methods represented by the VITS model offer a solution by synthesizing diverse and natural-sounding speech from text as a data aug- mentation technique. This approach expands the range of available speech patterns and linguistic variations beyond what traditional methods can achieve, thus addressing the shortcomings of tradi-tional data augmentation.

 In this paper, we compare the character-level ac- curacy of four traditional data augmentation meth- ods (Noise Augmentation, Volume Augmentation, Speed Perturbation, and SpecAugment) with VITS, Tacotron2, and Fastspeech, three TTS-based data augmentation methods, on ASR tasks at different multiples of train set expansion. To ensure the gen- erality of our experimental results, we evaluate per- formance across English, Mandarin, and Japanese languages. Specifically, we use the AN4, Ljspeech [\(Ito and Johnson,](#page-8-9) [2017\)](#page-8-9) and VCTK datases [\(Veaux](#page-9-1) [et al.,](#page-9-1) [2016\)](#page-9-1) for English, the THCHS30 [\(Wang and](#page-9-2) [Zhang,](#page-9-2) [2015\)](#page-9-2), CSMSC and AISHELL3 [\(Shi et al.,](#page-9-3) [2020\)](#page-9-3) datasets for Mandarin, the JUST [\(Kawahara](#page-8-10) [et al.,](#page-8-10) [2000\)](#page-8-10), JVS [\(Takamichi et al.,](#page-9-4) [2019\)](#page-9-4) and CSJ datasets [\(Maekawa,](#page-8-11) [2003\)](#page-8-11) for Japanese. Our findings indicate that the VITS-based data augmen- tation method achieves comparable performance to traditional methods, Tacotron2, and Fastspeech before migration, and demonstrates superior per-formance after migration.

 The contributions of our paper are as follows: 1) We conduct a comparative analysis between TTS- based data augmentation methods (Tacotron2, Fast- speech, and VITS) and traditional data augmen- tation methods on multilingual small datasets to simulate tasks with limited resources. This ap- proach aims to enhance the universality of our ex- perimental findings, providing insights into the ef- fectiveness of different augmentation methods. 2) We validate that models trained using VITS-based data augmentation method exhibit superior gen- eralization performance after transfer compared to models trained using other data augmentation

methods. This validation underscores the poten- **135** tial of VITS in enhancing model robustness and **136** mitigating domain shift issues, thus contributing to **137** advancements in the field of machine learning and **138** speech processing. **139** 

### 2 Related Work **<sup>140</sup>**

End-to-End Speech Recognition: End-to-end **141** speech recognition (ASR) has witnessed significant **142** advancements in recent years with models such as **143** Deep Speech [\(Hannun et al.,](#page-8-12) [2014\)](#page-8-12), Wav2Letter **144** [\(Collobert et al.,](#page-8-13) [2016\)](#page-8-13), and Listen, Attend and **145** Spell (LAS) [\(Chan et al.,](#page-8-14) [2015\)](#page-8-14) demonstrating high **146** accuracy in various applications. These models **147** simplify the traditional ASR pipeline by integrat- **148** ing acoustic, language, and pronunciation models **149** into a single neural network. **150**

However, their performance heavily depends on **151** the availability of large amounts of labeled data, **152** which poses a challenge in low-resource scenarios. **153** To address data scarcity, various data augmentation **154** techniques have been employed, such as SpecAug- **155** ment and Speed Perturbation. **156**

Text-to-Speech (TTS) Synthesis for Data Aug- **157** mentation: Recent advancements in TTS technol- **158** ogy have provided new opportunities for data aug- **159** [m](#page-9-5)entation in ASR. Models like Tacotron2 [\(Shen](#page-9-5) **160** [et al.,](#page-9-5) [2017\)](#page-9-5), FastSpeech [\(Ren et al.,](#page-9-6) [2019\)](#page-9-6), and **161** VITS [\(Kim et al.,](#page-8-15) [2021\)](#page-8-15) can generate high-quality **162** synthetic speech, which can be used to augment **163** training datasets for ASR systems. Tacotron2 syn- **164** thesizes natural-sounding speech by converting text **165** into mel-spectrograms and then using a vocoder **166** to generate waveforms. FastSpeech improves on **167** Tacotron2 by using a non-autoregressive approach, **168** making it faster and more stable. VITS combines **169** variational inference with adversarial learning to **170** produce even more natural and diverse speech. **171**

Despite the significant advances in TTS technol- **172** ogy over recent years, research on using TTS for **173** data augmentation to address data scarcity in low- **174** resource tasks remains scarce. Within the limited **175** research available, most studies have focused nar- **176** rowly on the straightforward application of TTS **177** for data augmentation in ASR, without thorough **178** comparisons between TTS as a novel augmentation **179** method and traditional augmentation techniques. **180** For example, [Rosenberg et al.](#page-9-7) evaluated the feasi- **181** bility of enhancing speech recognition performance **182** by synthesizing speech using two corpora from dif- **183** ferent domains. [Wang et al.](#page-9-8) explored using text- **184**  to-speech data augmentation to enhance children's speech recognition systems. Additionally, there has been insufficient investigation into how the use of these methods affects domain shift issues.

#### **<sup>189</sup>** 3 Methods

#### **190** 3.1 Traditional Data Augmentation Methods

 Speed Perturbation augments the train set by adjusting the playback speed of speech signals. Employing the data augmentation technique, mod- els become more adept at accommodating diverse speaking rates and intonations, consequently bol- stering its resilience and generalization capacity. **Suppose the original audio signal is**  $x(t)$ **, then the**  signal after Speed Perturbation, y(t), can be ex-pressed as:

$$
y(t) = x\left(\frac{t}{\alpha}\right) \tag{1}
$$

201 where  $\alpha$  is the Speed Perturbation factor. When 202  $\alpha$  < 1, the playback speed of the audio speeds 203 up; when  $\alpha > 1$ , the playback speed of the audio 204 slows down. In this paper, we set  $\alpha$  to 0.9, 1.1, and **205** 1.2, corresponding to accelerating to 111% of the **206** original speed, and slowing down to 91% and 83% **207** of the original speed, respectively.

 SpecAugment is a data augmentation technique commonly used in automatic speech recognition (ASR) to enhance model robustness and general- ization. It operates by applying three types of trans- formations to the spectrograms of speech signals: Time Warping (TW), Frequency Masking (FM), and Time Masking (TM). The augmented spectro- gram  $S'$  is obtained by sequentially applying these transformations to the original spectrogram S:

$$
S'(t, f) = TW(FM(TM(S(t, f)))) \qquad (2)
$$

**218** The formulas for Frequency Masking (FM), **219** Time Masking (TM), and Time Warping (TW) are **220** as follows:

$$
TW(S(t, f)) = S(t + \delta t, f) \tag{3}
$$

$$
FM(S(t, f)) = \begin{cases} 0 & \text{if } f_0 \le f \le f_0 + \delta f \\ S(t, f) & \text{otherwise} \end{cases}
$$

**222**

$$
TM(S(t, f)) = \begin{cases} 0 & \text{if } t_0 \le t \le t_0 + \delta t \\ S(t, f) & \text{otherwise} \end{cases}
$$
\n
$$
225 \tag{5}
$$

226 In this context,  $f_0$  denotes the random starting 227 **frequency for FM,**  $t_0$  **represents the random starting** 

time for TM,  $\delta f$  stands for the masking width for 228 FM, and  $\delta t$  serves as both the masking width for  $229$ TM and a random time offset for TW. **230**

Noise Augmentation is also a widely used tech- **231** nique in speech data augmentation. It aims to sim- **232** ulate different noise conditions found in real-world **233** environments, helping to strengthen the model's **234** robustness. In this paper, we implement Noise **235** Augmentation by injecting white noise into the **236** original audio. The amplitude of the added white **237** noise is set to specific proportions of the original **238** audio amplitude. The calculation formula for Noise **239** Augmentation is as follows: **240**

$$
y(t) = x(t) + \beta \cdot n(t) \tag{6}
$$

where  $y(t)$  is the augmented audio signal,  $x(t)$  is 242 the original audio signal,  $n(t)$  is the white noise 243 signal,  $\beta$  is the scaling factor for the white noise 244 amplitude. In our case,  $\beta$  takes the values 0.01, 245 0.02, and 0.05. **246**

Volume Augmentation is a data augmentation **247** technique designed to create varied datasets by ad- **248** justing the volume of audio signals. By modulating **249** the amplitude of these signals, it simulates record- **250** ings with different volume levels, thereby diversify- **251** ing the training data. The corresponding formulas **252** are given below: **253**

$$
y(t) = \gamma \cdot x(t) \tag{7}
$$

 $\gamma$  is the scaling factor for the audio signal's amplitude, representing the volume adjustment. In **256** this paper,  $\gamma$  is set to 0.5, 0.9, and 1.1. **257** 

Figure 1 illustrates the comparison between the **258** mel spectrogram of the original speech data and **259** the mel spectrograms of the speech data after ap- **260** plying four different traditional data augmentation **261** methods. From left to right in Figure 1 are the **262** original spectrogram, the spectrogram after Speed **263** Perturbation, the spectrogram after SpecAugment, **264** the spectrogram after Noise Augmentation, and **265** the spectrogram after Volume Augmentation. This **266** comparison can provide insights into the effective- **267** ness of these augmentation techniques in enhancing **268** the robustness and generalization capability of the **269** speech recognition model. **270** 

#### 3.2 VITS **271**

## Our approach leverages the Conditional Varia- **272** tional Autoencoder with Adversarial Learning for **273** End-to-End Text-to-Speech (VITS) model. VITS **274**

Figure 1: Comparison of Mel Spectrograms: Original Audio and Audio Augmented with Traditional Data Augmentation Methods

 is a cutting-edge architecture designed for text-to- speech (TTS) synthesis. It integrates a variational autoencoder (VAE) with adversarial learning tech- niques to generate high-quality speech waveforms directly from input text. Unlike traditional TTS models, VITS incorporates a conditional mecha- nism, enabling fine-grained control over the syn-thesized speech characteristics.

 The VITS model consists of an encoder-decoder architecture, where the encoder processes input text into a latent representation that captures the underlying features of the speech. The decoder then generates speech waveforms from this latent representation, producing natural-sounding speech with desired characteristics.

 During training, VITS utilizes a combination of loss functions, including spectral loss, duration loss, and adversarial loss, to ensure the synthesized speech's quality and fidelity to the input text. The corresponding equations are shown below.

$$
\mathcal{L}_{\text{spec}} = \text{MSE}(S_{\text{synth}}, S_{\text{tar}}) \tag{8}
$$

$$
\mathcal{L}_{dur} = MSE(D_{synth}, D_{tar}) \tag{9}
$$

$$
299 \qquad \mathcal{L}_{\text{adv}} = \log(1 - D(S_{\text{synth}})) - \log(D(S_{\text{tar}})) \tag{10}
$$

**296**

**298**

300 S<sub>synth</sub> and S<sub>tar</sub> represent the synthesized and tar- get speech spectrograms, respectively, in Equation 302 (7).  $D_{\text{synth}}$  and  $D_{\text{tar}}$  denote the synthesized and tar- get speech durations, respectively, in Equation (8).  $D(S_{\text{synth}})$  and  $D(S_{\text{tar}})$  are the discriminator's out- puts for the synthesized and target speech spectro- grams, respectively, in Equation (9). MSE stands for Mean Squared Error.

 VITS offers several advantages, including high- quality speech synthesis, fine-grained control over synthesized speech characteristics, and simplified training and inference procedures. These attributes make it a compelling choice for various TTS ap-plications, ranging from assistive technologies to

entertainment and communication systems. The **314** comparison of Mel Spectrograms between the orig- **315** inal audio and its corresponding VITS-synthesized **316** audio can be seen in Figure 2. **317** 

#### 3.3 ASR **318**

In our approach, we utilized a Transformer- **319** based ASR model architecture, consisting of Con- **320** former encoders and Transformer decoders. The **321** encoder module incorporated Conformer blocks, **322** which combined convolutional and self-attention 323 layers to capture both local and global information **324** from the input speech features. Meanwhile, the **325** decoder module employed Transformer blocks to **326** decode the encoded features and generate the final **327** transcript. 328

The Conformer block and Transformer decoder **329** can be defined as follows: **330**

 $\text{Conformer} = \text{Conv1D}(\text{SelfAttn}(x))$  (11) 331

 $\text{Decoder} = \text{SelfAttn}(h) + \text{FFN}(h)$  (12) 333

In the provided equations, x denotes the input 334 sequence, which constitutes the raw sequential data **335** processed by the model. h represents the output **336** of the encoder, which serves as the input to the de- **337** coder operation. FFN() refers to the feed-forward **338** neural network. SelfAttn() represents the opera- **339** tion of applying self-attention mechanism. **340**

During training, the model also optimized a com- **341** bination of loss functions, comprising spectral loss, **342** duration loss, and adversarial loss, to maintain the **343** accuracy of synthesized speech in relation to the **344** input text. **345**

Optimization was performed using the Adam **346** optimizer with gradient accumulation and gradient **347** clipping to stabilize training. Learning rate schedul- **348** ing was implemented using the Noam scheduler, **349** gradually increasing the learning rate during the **350** warm-up phase. **351** 

Figure 2: Comparison of Mel Spectrograms: Original Audio and VITS-synthesized Audio

 In addition, traditional data augmentation tech- niques along with VITS-based data augmentation methods were introduced at this stage to augment the training dataset for the ASR task, aiming to enhance the model's performance. These augmen- tation methods are used to expand the diversity and quantity of training samples, thus providing the model with more varied and representative data to learn from. By exposing the model to a wider range of acoustic variations and perturbations, the augmentation techniques encourage the model to learn more robust and invariant features, thereby improving its ability to generalize to unseen data and challenging acoustic environments.

#### **<sup>366</sup>** 4 Experiments

 In this paper, we train corresponding end-to-end ASR models using the AN4, JSUT, and THCHS30 datasets, and augment the data using synthesized speech obtained from VITS, Tacotron2, and Fast- speech models trained on the VCTK, ASHELL3, and JVS datasets. After migration, the trained ASR models will be tested for their performance on the LJSpeech, CSMSC, and CSJ datasets using newly

sampled test sets containing an equivalent number **375** of samples as the original test sets. The details of **376** the train set, dev set, and test set for the aforemen- **377** tioned datasets can be found in Table 1. **378**

During the experiments, we introduce four tra- **379** ditional data augmentation techniques alongside **380** three TTS-based data augmentation methods led **381** by VITS to enhance the train sets. To assess the ef- **382** fectiveness of these augmentation methods, we con- **383** duct a comparative analysis of model performance **384** at the character level on the test sets. These evalua- **385** tions enable us to gauge the models' performance **386** post-migration and investigate the impact of differ- **387** ent augmentation techniques on model generaliza- **388** tion capabilities. Through meticulous comparisons, **389** we provide evidence supporting the superiority of **390** the VITS-based data augmentation method. **391**

#### 4.1 Datasets **392**

AN4: The AN4 dataset encompasses a diverse col- **393** lection of speech recordings. With a sample rate **394** of 16000 Hz, it provides a comprehensive resource **395** for developing and evaluating speech recognition **396** algorithms. **397**

LJSpeech: The LJSpeech dataset is a public do- **398**

<b>End-to-end ASR Model Training</b>				<b>End-to-end TTS Model Training</b>				<b>Migration Testing</b>	
<b>Dataset</b>	train set	dev set	test set	<b>Dataset</b>	train set	dev set	test set	<b>Dataset</b>	test set
AN4	878	100	100	<b>VCTK</b>	36000	4000	4000	LJSpeech	100
THCHS30	10708	1340	1340	AISHELL3	68035	10000	10000	<b>CSMSC</b>	1340
<b>JSUT</b>	7196	250	250	<b>IVS</b>	15000	1000	1000	<b>CSJ</b>	250

Table 1: Datasets for ASR Model Training, TTS Model Training, and Migration Testing

 main speech dataset consisting of 13,100 short au- dio clips of a single speaker. Each clip is accom- panied by a transcription. The clips vary in length from 1 to 10 seconds, totaling approximately 24 hours of audio. The dataset has a sampling rate of 22.05 kHz.

 VCTK: The VCTK Corpus consists of speech data from 110 English speakers with diverse accents. Each speaker reads approximately 400 sentences. All recordings were downsampled to 48 kHz, and manually end-pointed.

 THCHS30: The THCHS30 dataset is an open Mandarin speech database. It contains speech data recorded in a quiet office environment, with a total duration exceeding 30 hours. The recordings have a sampling rate of 16 kHz.

 CSMSC: CSMSC is a dataset containing approx- imately 12 hours of effective speech data. The recordings are made by a female speaker aged be- tween 20 to 30 years. The speech data is provided with a sampling rate of 48 kHz.

 AISHELL3: The AISHELL-3 dataset is a multi- speaker Mandarin audio corpus. It comprises 88,035 recordings from 218 native speakers reading text from provided scripts with neutral emotions. The recordings were captured at a sampling rate of 44.1 kHz.

 JSUT: The JSUT dataset, a novel Japanese speech corpus, comprises approximately 10 hours of speech data recorded by a female native Japanese speaker. It offers speech data in 16-bit/sample RIFF WAV format with a sampling rate of 48 kHz, along with UTF-8 encoded transcriptions of the speech utterances.

 CSJ: The Corpus of Spontaneous Japanese (CSJ) is a comprehensive Japanese corpus extensively used for research in phonetics, linguistics, and pragmat- ics. It comprises approximately 650 hours of spon- taneous speech, equivalent to about 7,000k words. The speech materials are recorded using head-worn close-talking microphones and DAT, and down-sampled to 16 kHz with 16-bit accuracy. In this

experiment, only a portion of the data was utilized **441** for testing purposes. **442**

JVS: The JVS corpus provides high-quality au- **443** dio recordings from 100 native Japanese speakers, **444** including voice actors and actresses. It features **445** various speech styles such as normal, whispering **446** and falsetto voices, ensuring a diverse dataset. The **447** audio files are sampled at 24 kHz and encoded at **448** 16-bit depth, ensuring excellent fidelity and clarity. **449**

These datasets collectively support the develop- **450** ment and evaluation of end-to-end speech recog- **451** nition models across English, Mandarin, and **452** Japanese languages, enabling a thorough analysis **453** of different data augmentation techniques. **454**

### 4.2 ASR setup **455**

We utilize the train set, dev set, and test set de- **456** rived from the AN4, THCHS30, and JSUT datasets **457** for training, model tuning, and evaluation of the **458** ASR models, respectively. The acoustic features, **459** extracted from the raw audio data, consist of 80dimensional log Mel filterbank coefficients, which **461** have undergone cepstral mean and variance nor-<br> $462$ malization. **463** 

Text data is tokenized into subwords using **464** SentencePiece, incorporating special characters **465** "<unknown>", "<br/>blank>", underscore " ", and  $466$ "<sos/eos>" as sentence boundary markers. For  $467$ the AN4 English dataset, the vocabulary size is 30. 468 For the THCHS30 Mandarin dataset, it is 2669. For 469 the JSUT Japanese dataset, it is 2742. **470**

The model architecture primarily utilizes the **471** Transformer framework for training the automatic **472** speech recognition model. It employs a folded **473** batch type with a batch size of 64 and sets a max- **474** imum of 200 training epochs. Model parameters **475** are initialized using Xavier uniform distribution. **476** The selection criterion for the best model is based **477** on the maximum accuracy achieved on the dev set, **478** retaining the top 10 best models. **479**

Taking into account the linguistic and dataset- **480** specific characteristics, we made slight adjustments 481

Table 2: The table illustrates the character-level accuracy of ASR models on the test sets, achieved by expanding train sets using different data augmentation methods to various multiples. The labels 1x, 2x, 3x, and 4x denote the expansion multiples of the train sets. 4x Post-migration represents the accuracy of the ASR models after transfer, when the train sets have been expanded to four times its original size.

 to the structures of the ASR models for the three languages, aiming to achieve optimal performance. For the end-to-end ASR model trained on the AN4 dataset and THCHS30 dataset, the encoder pro- duces a 256-dimensional output, with 4 attention heads per mechanism and 12 Transformer blocks. Similarly, the decoder includes 4 attention heads per mechanism and 6 Transformer blocks. The model uses a hybrid loss function that combines spectral loss, duration loss, and adversarial loss, each with specific weights. It adopts the Adam op- timizer with a learning rate of 0.001 and employs a warm-up learning rate scheduler with 2500 warm- up steps. During the inference phase, the beam search algorithm is used, with a beam size set to **497** 10.

**498** For the end-to-end ASR model trained on the **499** JSUT dataset, the encoder consists of 12 blocks

with 2048 linear units, 4 attention heads per mech-  $500$ anism, and a 256-dimensional output. It incorpo- **501** rates dropout with a rate of 0.1 and utilizes a swish **502** activation function. Additionally, it includes rel- **503** ative position encoding and self-attention mecha- **504** nisms, as well as a convolutional neural network **505** (CNN) module with a kernel size of 15. The de- **506** coder comprises 6 transformer blocks with 2048 **507** linear units and a dropout rate of 0.1. The beam size 508 for the beam search algorithm during the inference **509** phase is set to 20. 510

## **4.3 TTS setup** 511

In our experimental setup for Text-to-Speech **512** (TTS), we leveraged the advanced capabilities of **513** the VITS (Variational Inference Transformer for **514** Speech Synthesis) model. This state-of-the-art **515** model, renowned for its remarkable performance **516** in generating natural-sounding speech, formed the **517**

**518** cornerstone of our TTS experiments.

 For the end-to-end TTS models in three lan- guages, we loaded pre-trained multi-speaker TTS model parameters trained on Aishell3, VCTK, and JVS datasets. By leveraging these pre-trained mod- els, we synthesized speech based on the text from the train sets of the ASR task, thereby augment- ing the scale of the training data and enhancing diversity.

#### **527** 4.4 Comparison

 In our experiments, we expand the train set to double, triple, and quadruple its original size us- ing different data augmentation techniques. Subse- quently, we evaluate the performance of the trained ASR models on the corresponding test sets in terms of character-level accuracy.

 As shown in Table 2, introducing either the TTS- based data augmentation method or traditional data augmentation techniques can enhance the perfor- mance of the trained models in English, Mandarin, and Japanese. In the scenarios of Mandarin and Japanese, the ASR models trained using the VITS- based data augmentation method achieved the high- est accuracy. In the scenario where the training datasets for all three languages are quadrupled, the accuracy of ASR models trained using the VITS- based data augmentation method consistently ranks within the top two. The average accuracy across the three scenarios is 77%. This performance is comparable to that of the Speed Perturbation and SpecAugment methods and significantly sur- passes the Noise Augmentation and Volume Aug- mentation methods, with an average accuracy im- provement of 4.8% and 2.5%, respectively, across all three scenarios. Besides, the performance of the VITS-based data augmentation method outper- forms Tacotron2 and Fastspeech, both of which are also TTS-based data augmentation methods.

 Due to differences in data distribution between datasets, often referred to as the domain shift prob- lem, trained models tend to suffer performance degradation when transferred to new datasets. In our experiments, we transferred the ASR models trained with various data augmentation methods to new datasets—LJSpeech, CSMSC, and CSJ—and tested their character-level accuracy on these new datasets. From Table 2, it can be observed that under the condition of a fourfold expansion of the train set in three languages, the performance degra-dation of the ASR models trained using the VITS- based data augmentation method is the least when **568** transferred to new datasets, averaging a decrease **569** of 10.7%. Conversely, among other data augmenta- **570** tion methods, Speed Perturbation exhibits the best **571** performance post-migration, with an average de- **572** crease of 14.7% across the three scenarios. Follow- **573** ing model transfer, the ASR models trained using **574** the VITS-based data augmentation method con- **575** sistently achieve the highest accuracy in all three  $576$ scenarios, with an average character-level accu- **577** racy of 66.4%, surpassing Speed Perturbation, the **578** second-best performer, by approximately 3.5%.

Overall, ASR models trained using the VITS- **580** based data augmentation method outperform most **581** data augmentation methods in terms of perfor- **582** mance before model transfer, slightly outpacing **583** SpecAugment and Speed Perturbation. After **584** model transfer, the character-level accuracy of ASR **585** models trained using the VITS-based data augmen- **586** tation method significantly surpasses that of other **587** data augmentation methods in all scenarios, with **588** the smallest decrease in accuracy compared to other **589** methods. **590**

These experimental results clearly demonstrate **591** the advantages of the VITS-based data augmen- **592** tation method over traditional data augmentation **593** methods. Additionally, they also confirm the superi- **594** ority of the VITS-based data augmentation method **595** among TTS-based data augmentation methods. **596**

#### 5 Conclusion and Future Work **<sup>597</sup>**

Through comprehensive experiments, we **598** demonstrate that integrating synthetic speech **599** generated by VITS-based data augmentation **600** into ASR train sets significantly improves the **601** performance and generalization of ASR systems in **602** low-resource scenarios. Moreover, ASR models **603** trained with VITS-based data augmentation exhibit **604** enhanced resilience to domain shifts and better **605** adaptability across various linguistic contexts **606** compared to the remaining data augmentation **607** methods. Our study underscores the potential **608** of TTS represented by VITS as a valuable data **609** augmentation method, offering a practical solution **610** to the challenges faced by ASR systems in **611** low-resource scenarios. Future research could **612** concentrate on advancing VITS-based TTS **613** models to maximize augmentation benefits by **614** enhancing fidelity, adaptability across languages, **615** and scalability to broader ASR applications. **616**

## **<sup>617</sup>** Limitations

 Despite the promising results obtained, several limitations should be acknowledged. First, the eval- uation was conducted on a limited set of languages (English, Mandarin, and Japanese), potentially lim- iting the generalizability of findings to other low- resource languages with different phonetic struc- tures or linguistic characteristics, for example, Ti- betan. Second, the impact of hyperparameter set- tings and specific implementation details of the VITS-based augmentation method were not exten- sively explored, which could influence its effective- ness across different datasets and tasks. Finally, while improvements in model robustness were ob- served during testing, longitudinal studies to assess the long-term stability of models under varying con- ditions are warranted. Further in-depth research is needed to fully understand and address these limita- tions, and the path ahead requires continuous effort and dedication.

### **<sup>637</sup>** Ethical Statement

 This study adheres strictly to ethical principles, ensuring the confidentiality of data and ethical con- duct in all research practices. The research rigor- ously upholds the principles of beneficence, non- maleficence, and justice. All data utilized in this study are sourced exclusively from publicly avail-able datasets.
