GENERATING MODEL PARAMETERS FOR CONTROL-LING: PARAMETER DIFFUSION FOR CONTROLLABLE MULTI-TASK RECOMMENDATION

Anonymous authors

Paper under double-blind review

ABSTRACT

Commercial recommender systems face the challenge that task requirements from platforms or users often change dynamically (e.g., varying preferences for accuracy or diversity). Ideally, the model should be re-trained after resetting a new objective function, adapting to these changes in task requirements. However, in practice, the high computational costs associated with retraining make this process impractical for models already deployed to online environments. This raises a new challenging problem: how to efficiently adapt the learning model to different task requirements by controlling model parameters after deployment, without the need for retraining. To address this issue, we propose a novel controllable learning approach via **Pa**rameter **Di**ffusion for controllable multi-task **Rec**ommendation (PaDiRec), which allows the customization and adaptation of recommendation model parameters to new task requirements without retraining. Specifically, we first obtain the optimized model parameters through adapter tunning based on the feasible task requirements. Then, we utilize the diffusion model as a parameter generator, employing classifier-free guidance in conditional training to learn the distribution of optimized model parameters under various task requirements. Finally, the diffusion model is applied to effectively generate model parameters in a test-time adaptation manner given task requirements. As a model-agnostic approach, PaDiRec can leverage existing recommendation models as backbones to enhance their controllability. Extensive experiments on public datasets and a dataset from a commercial app, indicate that PaDiRec can effectively enhance controllability through efficient model parameter generation. The code is released at https://anonymous.4open.science/r/PaDiRec-DD13e.

1 INTRODUCTION

036

Traditional recommender systems are usually designed to improve accuracy by analyzing user behaviors and contextual data to uncover users' potential interests and preferences (Kang & McAuley, 2018; Hidasi et al., 2016). Nowadays, recommendation models place greater emphasis on multiple important aspects of the recommended results (also called multi-task recommendation), such as diversity (Xia et al., 2017), fairness (Oosterhuis, 2021), etc. Existing multi-task recommendation models are typically static (Zhang & Yang, 2021; Sener & Koltun, 2018), meaning that the preference weights for each aspect (e.g., accuracy or diversity) are predefined and fixed during both training and testing. Once the *static* preference weights are determined, the training process can employ various optimization algorithms to find the optimal solution.

However, in practical scenarios, the preference weights for different aspects often *change dynamically* across both context and time. From a commercial perspective, different application scenarios may require varying preference weights for different performance aspects of the recommendation model to meet specific business needs. For instance, the checkout page emphasizes product diversity, while the product detail page prioritizes accuracy by recommending similar items. From the users' perspective, different user groups may have distinct preferences, and even the same users may have changing information needs over time. For example, a user may prefer highly accurate recommendations when browsing a specific item category, but over time, such precision might diminish their interest, prompting a preference for more diverse categories. To address the above

dynamic information needs of users or platforms, this paper focuses on enhancing the controllability of recommendation models at test time, specifically in the context of controllable multi-task recommendation.

Traditional multi-task learning approaches face challenges in addressing the issue of dynamically changing preference weights. More specifically, when preference weights change, they require resetting the objective function, re-training the recommendation model based on the new objective, 060 and then redeploying the updated model. However, while this approach enables the integration of 061 various optimization methods, the retraining process is highly time- and resource-intensive, render-062 ing it impractical — especially since rapid response time is critical during online recommendation 063 phases. For instance, during promotional events, commercial stores often require real-time flow 064 control to adjust their recommendation strategies, with changes ideally implemented immediately. Several studies have recognized the importance of dynamically adjusting models based on changing 065 preferences. Wortsman et al. (2022) used simple parameter merging across multiple task-specific 066 models, and Chen et al. (2023) employed discriminative models to generate parameters for multi-067 task re-ranking problem. While they reduce response time and aim to enhance control over the 068 model, they struggle with approximating the optimal model (which we assume can be achieved 069 through retraining with given preference weights), potentially leading to suboptimal solutions. To achieve both efficient test-time adaptation to changing preferences and preserve the approximate op-071 timal performance that retraining offers, we leverage the strengths of diffusion models in generating high-performance model parameters (Schürholt et al., 2022; Knyazev et al., 2021; Wang et al., 2024) 073 for recommendation model. Additionally, we utilize conditional control (Ho & Salimans, 2022) to 074 ensure controllability at test-time with changing preference weights as conditions.

075 In this work, we propose a novel parameter generation approach for controllable multi-task recom-076 mendation by leveraging a generative model to efficiently generate task-specific model parameters at 077 test time based on varying task requirements (i.e., the preference weights for different performance 078 metrics), effectively addressing the challenges posed by rapidly changing requirements and the high 079 cost of retraining models. The proposed approach, termed PaDiRec, begins by formulating an objective function aligned with task-specific preference weights, and through advanced optimization 081 techniques, we fine-tune model parameters using adapter tuning. We then train a diffusion model to learn the conditional distribution of these optimized adapter parameters under various task re-083 quirements, where the classfier-free guidance training strategy is employed to perform conditional training. Once trained, during online testing, the diffusion model can generate task-specific adapter 084 parameters with the task requirement as condition, which can be integrated with different sequen-085 tial recommendation backbones to produce recommendation lists that meet the specified requirements. Additionally, PaDiRec is both model-agnostic and algorithm-agnostic, making it flexible 087 and compatible with various recommendation models and optimization strategies. We summarize our contributions as follows:

- We formally define the problem of controllable multi-task recommendation (CMTR), which focuses on the model's ability to adapt to dynamic changes in preferences for different metrics during online testing.
- We present PaDiRec, a diffusion model-based approach that generates model parameters conditioned on task-specific preference weights, providing enhanced control and flexibility by controlling model parameters in multi-task learning settings.
- Extensive experiments on two public datasets and an industrial dataset demonstrate that PaDiRec achieves superior performance towards controllability of multi-task recommendation while retaining recommendation performances.

2 PROBLEM FORMULATION AND ANALYSES

Given a user $u \in \mathcal{U}$ and a set of candidate items $\mathcal{C} = \{c_k\}_{k=1}^{|\mathcal{C}|}$ where $|\mathcal{C}|$ denotes the total number of candidate items. the historical interaction sequence of user u of length h is denoted by $S_u = \{c_1^u, c_2^u, \ldots, c_h^u\}$ (also called user history), where $c_k^u \in \mathcal{C}, k \in \{1, 2, \ldots, h\}$. For a **recommendation task** $i \in \{1, 2, \ldots, N\}$, a recommender system aims to find the following item list L_i^* among all possible lists $\{L\}$ composed by candidate items from \mathcal{C} :

090

092 093

094

095 096

098

099

$$L_i^* = \underset{L}{\arg\max} R_i(L \mid S^u, \mathcal{C}), \tag{1}$$

where R_i denotes the reward function corresponding to task *i*, which evaluates the recommender system's performance with respect to task *i*. More specifically, modern recommender systems often evaluate performance from multiple perspectives, the reward function in Eq. (1) for task *i* can be expressed as the following linear combination of *p* utility functions $\{U_i\}_{i=1}^p$:

$$R_i(L(S_u, \mathcal{C})) = \sum_{j=1}^p w_i^j U_j(L \mid S_u, \mathcal{C}),$$
(2)

which allows task *i* to be quantified by a set of **preference weights** $w_i = \{w_i^j\}_{j=1}^p \in \mathcal{W}$ for the various utilities, where \mathcal{W} denotes the preference weight space that is a simplex.

Then, we can provide the definition of **controllable multi-task recommendation (CMTR)**. The 118 goal of CMTR is to find a recommendation model f_{θ} , parameterized by $\theta \in \Theta$, such that the item 119 lists output during test time, $L = f_{\theta}(S_u, C)$, can adapt to changes in tasks (i.e., adapt to variations in 120 the corresponding preference weights in Eq. (2)). As an example, after the recommendation model 121 f_{θ} is deployed, when the preference weights for different utilities (e.g., accuracy and diversity) need 122 to shift from $w_i = \{w_i^j\}_{j=1}^p$ (i.e., task i) to $w_k = \{w_k^j\}_{j=1}^p$ (i.e., task k) based on user or platform 123 requirements, we say that the recommendation model f_{θ} is **controllable** if it can ensure that its 124 reward remains at a high level regardless of how the preference weights change. Ideally, to accom-125 modate changes in tasks, we could retrain the recommendation model after receiving new preference 126 weights to update its parameters, resulting in $f_{\hat{\theta}}$ that maintains a high reward. However, for an al-127 ready deployed model, the time required for retraining is impractical and unacceptable. Another 128 straightforward method would be to store N sets of task-specific parameters corresponding to the 129 preference weights for N tasks at the time of deployment, and load them when a new task arises at 130 test time. However, when considering a continuous preference weight space where the number of 131 tasks N tends to infinity (i.e., a continuous task space), this discrete method becomes impractical due to storage limitations and cannot accommodate fine-grained or continuous task variations. 132

133 To efficiently and effectively adapt to changes in tasks, this paper focuses on controlling the model 134 parameters θ of the recommendation model f_{θ} to accommodate the varying preference weights of 135 new tasks. More specifically, we treat the preference weights as variables and model the relationship 136 between the preference weight space \mathcal{W} and the model parameter space Θ during training, transforming the time- and resource-intensive retraining problem at test time into an efficient inference 137 problem. Formally, we aim to find a function $g_{\boldsymbol{\xi}}: \mathcal{W} \to \Theta$ (where $\boldsymbol{\xi}$ denotes the parameter of g) that 138 generates model parameters capable of achieving a high reward given the new preference weights 139 \boldsymbol{w}_k for any task k at test time: 140

141 142

143

112 113 114

$$R_k(L(S_u, \mathcal{C})) = \sum_{j=1}^p w_k^j U_j(f_{\boldsymbol{\theta}_k}(S_u, \mathcal{C}) \mid \boldsymbol{\theta}_k = g_{\boldsymbol{\xi}}(\boldsymbol{w}_k)).$$
(3)

In contrast to traditional multi-task recommendation (MTR), which focuses only on *fixed* preference weights for different utilities, our defined CMTR emphasizes how the model adapts to *dynamic* changes in preference weights after deployment. This shift means that in traditional MTR, each task corresponds to a *single* utility, whereas in CMTR, each task is associated with *multiple* utilities combined through a linear weighting, with combination coefficients determined by a set of task-specific preference weights. As a result, CMTR places greater emphasis on test-time adaption to handle dynamic task requirements, introducing new challenges for CMTR model training and construction compared to MTR.

3 PADIREC: THE PROPOSED APPROACH

In this section, we provide a detailed description of the proposed approach, **PaDiRec**. PaDiRec utilizes a conditional generative framework designed to directly learn from the optimized parameters of recommendation models tailored to specific tasks. This pre-training process enables the generation of new model parameters based on specified preference weights at test time.

158 159

- 3.1 Algorithm Overview
- As shown in Figure 1, we provide an illustrative overview of the proposed PaDiRec, which contains the following three phases. (1) *Preparation of adapters*: the left part in Figure 1 shows the training

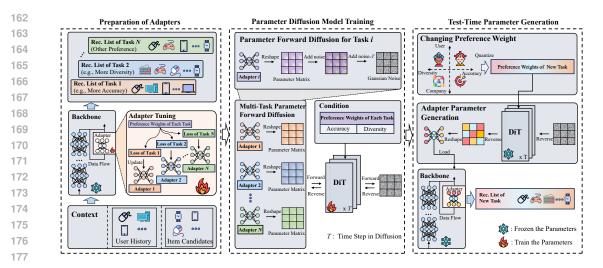

Figure 1: An overview of the proposed PaDiRec. Details are shown in Sec. 3.1

process of the recommendation model, from which we can obtain a collection of optimized adapter 181 parameters for feasible specific task by sampling the preference weights. Note that we focus on 182 two utilities: accuracy and diversity. As defined in Eq. (3), each task is represented by a set of 183 preference weights for these two utilities. (2) Parameter diffusion model training: the middle part in Figure 1 illustrates the conditional training procedure of the generative model g_{ξ} (i.e., DiT) with 185 the optimized adapter parameters as initial data and the corresponding preference weights as condition, thus generating meaningful adapter parameters from Gaussian noise given preference weights. (3) Test-time parameter generation: the right part in Figure 1 shows how we utilize the trained 187 DiT model during the test phase to adapt to dynamically changing task requirements (i.e., prefer-188 ence weights for diversity and accuracy). First, we quantify these task requirements as preference 189 weights. Next, we employ the trained DiT model to generate adapter parameters in real time, using 190 these preference weights as inputs, which are then combined with the backbone to directly support 191 the recommendation task. In the following subsections, we elaborate on the details of these phases. 192

179

3.2 PREPARATION OF ADAPTERS

Our goal is to construct the parameters of optimized recommendation models under different preference weights to prepare data for the generative model. Thus, this section is organized into three parts: the structure of the recommendation model, the construction of task-specific objective functions, and the tuning process for the recommendation model parameters.

200 Model structure. As shown in the left module of Figure 1, sequential recommendation models take 201 user history and candidate items as input. Guided by the objective function (i.e., loss function), the 202 model learns the underlying relationships within the user history, ultimately generating a recom-203 mendation list (i.e., Rec. List) from the candidate items. Existing recommender systems based on 204 deep neural networks can be quite large, and making significant invasive modifications typically requires retraining the entire model, which is often prohibitively expensive in industrial applications. 205 To address this, our approach introduces an adapter module, which can be seamlessly integrated into 206 existing sequential recommendation models. Specifically, we incorporate the adapter using a resid-207 ual connection, attaching it to the last layer of the backbone model. In this setup, the backbone is 208 set to retain the original recommendation capabilities, while the adapter is responsible for adapting 209 to specific tasks. 210

Objective function construction. To obtain the optimized task-specific adapter parameters under CMTR setting (as shown in Sec. 2), we first focus on the construction of loss functions based on different preference weights of each task. Specifically, we directly convert the reward maximization problem (reward defined in Eq. (2)) into a loss minimization problem. Given a specific set of preference weights $w_i = \{w_i^j\}_{j=1}^p \in \mathcal{W}$, which represent preference weight for the *j*-th utility in the requirement of task *i*. Here, we focus on two utilities including diversity loss $\ell_{\text{diversity}}$ and accuracy loss ℓ_{accuracy} in each task (i.e., p = 2). Thus, the total loss function for task *i* is

$$\ell_i = w_i^1 \ell_{\text{accuracy}} + w_i^2 \ell_{\text{diversity}}.$$
(4)

Adapter tuning. Based on above total loss function, we decompose the recommendation model 220 parameters θ into two components: task-specific adapter parameters, denoted as θ_a and task-221 independent backbone parameters, denoted as θ_b . Accordingly, optimizing the model is divided 222 into two phases. The *first phase* focuses on optimizing the backbone parameters $\theta_{\rm b}$, which uses the standard BCE loss to train the backbone model thus preserving the original recommendation 224 accuracy. The second phase is about the optimization of the task-specific adapter parameters θ_a , 225 which aims at improving the system's adaptability to different tasks. During the second phase, the 226 backbone parameters are frozen to prevent them from being tailored to any specific task, whereas 227 the adapter is trainable. More specifically, in the second phase, we train the task-specific adapter 228 parameters based on two loss functions as in Eq. (4), one for accuracy and one for diversity. For the accuracy loss ℓ_{accuracy} , we continue to use BCE as the loss function to guide the model toward accu-229 racy. For the diversity loss $\ell_{\text{diversity}}$, inspired by Yan et al. (2021), we apply a differentiable smoothing 230 of the α -DCG metric and adapt it to the recommendation setting. Consider $|\mathcal{C}|$ candidate items and 231 $|\mathcal{M}|$ categories, where each item may cover 0 to $|\mathcal{M}|$ categories. The category labels are denoted 232 as $y_{k,l} = 1$ if item k covers category m, and $y_{k,l} = 0$ otherwise, where $k \in \{0, \dots, |\mathcal{C}| - 1\}$, 233 $l \in \{0, \dots, |\mathcal{M}| - 1\}$. Based on the α -DCG, we design a differentiable diversity loss function: 234

218 219

240 241 242

247

248

254

255

 $\ell_{\text{diversity}} = -\sum_{k=1}^{|\mathcal{C}|} \sum_{l=1}^{|\mathcal{M}|} \frac{y_{k,l}(1-\alpha)C_{k,l}}{\log_2(1+\text{Rank}_k)},$ (5)

where α is a hyper parameter between 0 and 1, Rank_k is the soft rank of the item k, and $C_{k,l}$ is the number of times the category l being covered by items prior to the soft rank Rank_k. That is:

$$\operatorname{Rank}_{k} = 1 + \sum_{j \neq k} \operatorname{sigmoid}\left((s_{j} - s_{k})/T\right), \quad C_{k,l} = \sum_{j \neq k} y_{j,l} \cdot \operatorname{sigmoid}\left((s_{j} - s_{k})/T\right), \quad (6)$$

where s_k denotes the relevance score of the k-th candidate item output by the model. For task *i*, we denote θ_i as the model parameters including task-specific adapter parameters θ_i^a and fixed backbone parameters θ_i^b . Overall, based on the total loss in Eq. (4), the task-specific optimization process of θ_i^a for task *i* can be formulated as follows:

$$\boldsymbol{\theta}_{i}^{\mathrm{a}} = \underset{\boldsymbol{\theta}_{i}^{\mathrm{a}}}{\operatorname{arg\,min}} \quad w_{i}^{1} \ell_{\mathrm{accuracy}} + w_{i}^{2} \ell_{\mathrm{diversity}}, \tag{7}$$

where $w_i = \{w_i^1, w_i^2\} \in \mathcal{W}$ is sampled from [0, 1]. We employ the standard Adam optimizer to optimize these parameters. Then we transform the parameters of each task-specific adapter into a matrix-based format and these optimized parameters serve as the ground truth for the subsequent generative model training process.

3.3 PARAMETER DIFFUSION MODEL TRAINING

256 The optimized adapter parameters and corresponding preference weights obtained from Sec. 3.2 are used as the training data for the diffusion model. We employ a generative model g_{ξ} parameterized 257 by $\boldsymbol{\xi}$ to learn the process of generating model parameters. Specifically, $g_{\boldsymbol{\xi}}$ is applied to predict the 258 conditional distribution of the adapter parameter matrices $p_{g_{\xi}}(\theta_i^a|w_i)$ given the preference weights 259 w_i , where i corresponds to the task i. We adopt diffusion models (Ho et al., 2020) as our genera-260 tive model due to its efficacy in various generation tasks (Li et al., 2022; Ho et al., 2022a; Vignac 261 et al., 2023) and its superior performance on multi-modal conditional generation (Bao et al., 2023; 262 Nichol et al., 2022; Saharia et al., 2022). We train the diffusion model to sample parameters by gradually denoising the optimized adapter parameter matrix from the Gaussian noise. This process 264 is intuitively reasonable as it intriguingly mirrors the optimization journey from random initializa-265 tion which is a well-established practice in existing optimizers like Adam. For task i, our denoising 266 model takes two parts as the input: a noise-corrupted adapter parameter matrix $\theta_{i,t}^{a}$, and a set of preference weights w_i , with t representing the step in the forward diffusion process. The training 267 objective is as follows: 268

$$\ell_{\text{diff}} = \mathbb{E}_{\boldsymbol{\theta}_{i,0}^{a}, \epsilon \sim \mathcal{N}(0,1), t} \left[\left\| \epsilon - \epsilon_{\boldsymbol{\xi}}(\boldsymbol{\theta}_{i,t}^{a}, \boldsymbol{w}_{i}, t) \right\|^{2} \right],$$
(8)

270 where ϵ denotes the noise to obtain $\theta_{i,t}^{a}$ from $\theta_{i,0}^{a}$, and the denoising model $\epsilon(\cdot)$ is the main part of the 271 generative model $g_{\boldsymbol{\xi}}$. We assume that the parameters of $g_{\boldsymbol{\xi}}$ primarily originate from the denoising 272 model. For simplicity, we denote the denoising model as ϵ_{ξ} . To conduct condition training in a 273 classifier-free guidance manner (Ho & Salimans, 2022), we use the denoising model to serve as 274 both the conditional and unconditional model by simply inputting a null token \emptyset as the condition (i.e., preference weights w_i) for the unconditional model, i.e. $\epsilon_{\boldsymbol{\xi}}(\boldsymbol{\theta}_{i,t}^a,t) = \epsilon_{\boldsymbol{\xi}}(\boldsymbol{\theta}_{i,t}^a,\boldsymbol{w}_i = \emptyset,t)$. The 275 probability of setting w_i to \emptyset is denoted as p_{uncond} and is configured as a hyperparameter. Alg. 1 276 in Appendix illustrates the detailed procedure.

3.4 TEST-TIME PARAMETER GENERATION

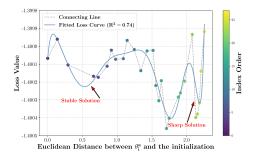

After the diffusion is trained, we can generate the parameters $\theta_{n,0}^{a}$ by querying g_{ξ} with a new set of preference weights w_n , specifying the desired preference weights for accuracy and diversity of new task n. Then the generated adapter parameter $\theta_{n,0}^a$ for that new task is directly loaded into the adapter, which is connected to the backbone. This forms a new customized recommendation model that responds to the preference weights of the new task. The generation is an iterative sampling process from step t = T to t = 0, which denoises the Gaussian noise into meaningful parameters taking specific preference weights as the condition. The generation process is formulated as follows:

$$\tilde{\epsilon}_{\boldsymbol{\xi}}(\boldsymbol{\theta}_{n,t}^{a},\boldsymbol{w}_{n},t) = (1+\gamma)\epsilon_{\boldsymbol{\xi}}(\boldsymbol{\theta}_{n,t}^{a},\boldsymbol{w}_{n},t) - \gamma\epsilon_{\boldsymbol{\xi}}(\boldsymbol{\theta}_{n,t}^{a},t),$$
$$\boldsymbol{\theta}_{n,t-1}^{a} = \frac{1}{\sqrt{\alpha_{t}}} \left[\boldsymbol{\theta}_{n,t}^{a} - \frac{\beta_{t}}{\sqrt{1-\overline{\alpha_{t}}}} \tilde{\epsilon}_{\boldsymbol{\xi}}(\boldsymbol{\theta}_{n,t}^{a},\boldsymbol{w}_{n},t) \right] + \sigma_{t}\boldsymbol{z}_{t},$$
(9)

291 where \boldsymbol{z}_t $\sim \mathcal{N}(\mathbf{0}, \mathbf{I})$ for t > 1 and $\mathbf{z}_t = \mathbf{0}$ for $t = 1, \beta_t$ 292 Alg. 2 in Appendix illustrates the detailed \in [0,1] . α_t, γ 293 Specifically, after generating the adapter parameter matrix, we reshape it to obtain the adapter 295 parameters (for simplicity, we do not distinguish 296 between the notations used before and after the 297 reshaping). The generated adapter parameter is 298 directly load into the adapter architecture. Then 299 keeping the backbone parameters $\theta_n^{\rm b}$ and the adapter parameters $\theta_{n,0}^{a}$ fixed, the recommenda-300 tion model is directly applied to extract features 301 from the user history interactions and score candi-302 date items to generate a recommendation list that 303 aligns with the preference weights of the new task. 304

4 DISCUSSIONS ON THE ROBUSTNESS OF PARAMETER DIFFUSION

In experiments of Sec. 5, we found that parameter diffusion in our PaDiRec can generate model 310 parameters that differ from those obtained by re-311 training the total loss in Eq. (7), yet still achieve 312 good recommendation performance and controlla-313 bility. This leads us to hypothesize that parameter 314

procedure.

=

Figure 2: The relationship between the loss values in Eq. (7) and the adapter parameters $\boldsymbol{\theta}_i^{\mathrm{a}}$ (with the preference weights $w_i^1=0.3$ and $w_i^2 = 0.7$) on MovieLens 1M using SAS-Rec as backbone. The index order indicates the number of epochs after convergence. The detailed settings are shown in Sec. A.2

diffusion may find more robust model parameters through model parameter generalization. To vali-315 date this hypothesis, we continued training the adapter parameters for multiple epochs after the total 316 loss had converged, analyzing the relationship between the adapter parameters and the values of the 317 loss Eq. (7). We employed polynomial fitting to model the relationship between the data points, 318 estimating the functional relationship between the loss values and model parameters, achieving a 319 goodness of fit of $R^2 = 0.74$. As illustrated in Figure 2, we observe that the solutions of the total 320 loss exhibit different characteristics under various model parameters. Specifically, there are rela-321 tively flat solution sets, referred to as "Stable Solutions", as well as solution sets with more dramatic fluctuations, termed "Sharp Solutions". Furthermore, as verified in RQ1 of Sec. 5.3, we observe that 322 the parameter diffusion in PaDiRec effectively learns the set of robust "Stable Solutions", thereby 323 enhancing controllability while maintaining high performance.

5 EXPERIMENTS

We conducted experiments to evaluate the performance of PaDiRec on two public datasets and an industrial dataset for sequential recommendation.

5.1 EXPERIMENT SETTINGS

Dataset. We used two public datasets, MovieLens 1M¹ and Amazon Food², and the Industrial Data from a electronics commercial store. Detailed descriptions of the datasets and preprocessing methods can be found in Appendix A.3.

Baselines. The baselines are as follows. Retraining as Eq. (2), which is considered optimal.
Soup (Wortsman et al., 2022), a classic algorithm for model merging. MMR (Carbonell & Goldstein, 1998), a rule-based post-process policy. CMR (Chen et al., 2023), an re-rank algorighm utilizing hypernetwork to achieve dynamic preference of changing. LLM (Appendix A.11), a prompt-based method for controllable recommendation. Details about all the baselines are shown in Appendix A.4

356 **Metrics.** We propose evaluating performance from two dimensions. Specifically, we use Hyper-357 volume (HV) (Guerreiro et al., 2021) to measure the performance of the algorithm on each task, 358 particularly in terms of the trade-offs between accuracy and diversity. The average HV (denoted as Avg.HV) across multiple tasks is used to assess the overall performance of the algorithm in balanc-359 ing both objectives (accuracy and diversity). To eliminate the differences in scale between the two 360 objectives, we normalize the performance on each objective. Additionally, we utilize the Pearson 361 correlation coefficient to evaluate the alignment between the algorithm's performance across differ-362 ent tasks and the optimal model, providing insight into the algorithm's controllability. Pearson r-a, 363 **Pearson r-d** measure the correlation between the algorithm and the optimal in terms of accuracy 364 (NDCG@10) and diversity (α -NDCG@10). 365

365 366 367

5.2 EXPERIMENTAL RESULTS

We conducted experiments to address the following two questions: i) How transferable is PaDiRec, specifically in terms of its ability to adapt to different backbone algorithms? ii) How does PaDiRec perform compared to other baselines on each specific task? The results are presented in Table 1.

To answer the first question, we used commonly adopted sequential recommendation models as backbones (e.g., SASRec (Kang & McAuley, 2018), GRU4Rec (Hidasi, 2015), and TiSASRec (Li et al., 2020b)) and conducted extensive experiments across three datasets. Specifically, we evaluated PaDiRec's performance under various task descriptions by measuring NDCG@10 and α -NDCG@10. The accuracy weight w_{acc} varies from 0 to 1 in intervals of 0.1, with the corresponding

347

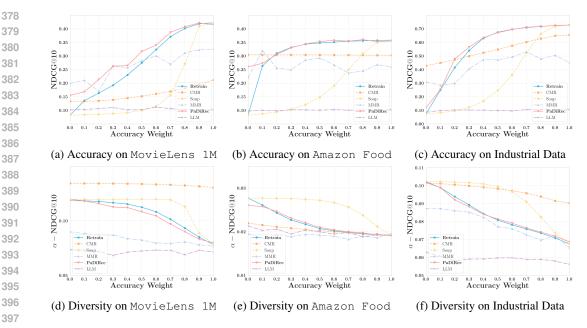

Figure 3: The accuracy and diversity curve of PaDiRec and other baselines in NDCG@10 and α -NDCG@10 across accuracy weights ranging from 0 to 1, with intervals of 0.1. The backbone is TiSASRec, results on other backbones are shown in Appendix A.6

398

399

diversity weight set as $w_{\rm div.} = 1 - w_{\rm acc.}$. We then post-processed NDCG@10 and α -NDCG@10 403 across different tasks to compute Avg.HV, Pearson r-a, and Pearson r-d. These metrics respectively 404 evaluate the quality of multi-objective optimization on individual tasks and the controllability across 405 multiple tasks. Overall, across the three backbones and three datasets, PaDiRec consistently ranked 406 among the top two performers across all three evaluation metrics. Notably, in most cases, the top 407 two of Avg.HV are Retrain and PaDiRec, indicating that PaDiRec's performance in multi-objective 408 trade-offs is on par with, or even superior to, Retrain. Specific exceptions occurred, such as on 409 the Amazon Food dataset with GRU4Rec as the backbone and the Industrial Data with 410 TiSASRec as the backbone, where CMR achieved the best Avg.HV. This is because CMR is not in-411 fluenced by task descriptions and thus maintains consistently high NDCG@10 scores (as shown in 412 Figure 3 and further explained in response to question ii). For Pearson r-a and Pearson r-d, PaDiRec demonstrated strong correlations with the Retrain method, indicating that PaDiRec closely aligns 413 with Retrain (which we assume to be optima) in terms of accuracy (NDCG@10) and diversity (α -414 NDCG@10) across different tasks. On the Amazon Food dataset with SASRec as the backbone, 415 CMR achieved the highest Pearson r-d. However, its Pearson r-a was negative, indicating a lack of 416 control and a collapse in accuracy. 417

To address the second question, we presented the specific performance of PaDiRec under each task 418 description using TiSASRec as the backbone across three datasets, as shown in Figure 3 (more re-419 sults are shown in Appendix. A.6). It is observed that in all three datasets, PaDiRec's NDCG@10 420 progressively increases with higher accuracy weights, while α -NDCG@10 decreases correspond-421 ingly due to the simultaneous reduction in diversity weight. These trends demonstrate the effective-422 ness of our algorithm in controllability. Notably, assuming that Retrain is optimal, PaDiRec exhibits 423 strong consistency with the Retrain method. In contrast, MMR, as a post-processing algorithm, 424 shows variability because varying degrees of diversity manipulation can disrupt the original recom-425 mendation list, uncontrollably affecting its accuracy. The Soup method merges the parameters of 426 accuracy and diversity models based on their weights, aligning closely with the Retrain model when 427 accuracy weights are extreme but showing significant deviations in other tasks. This indicates that 428 tasks do not follow a simple linear relationship with different preference weights, and Soup makes 429 overly strong assumptions about this relationship. CMR demonstrates inconsistent performance across different datasets. On the MovieLens 1M dataset, CMR aligns well with the original de-430 scriptions by exhibiting high diversity. However, on the other two datasets, it shows a stable yet 431 uncontrollable state; for instance, on the Amazon Food dataset, CMR maintains high accuracy

Approach	Backbone	MovieLens 1M(sec.)	Amazon Food(sec.)	Industrial Data(sec.)
	SASRec	293.10 ± 11.61	91.01 ± 2.34	46.82 ± 3.25
Retrain	GRU4Rec	281.60 ± 17.36	92.39 ± 4.28	49.54 ± 2.38
	TiSASRec	303.80 ± 9.09	105.40 ± 7.66	52.47 ± 4.64
	SASRec	2.68 ± 0.36	2.64 ± 0.36	2.55 ± 0.25
PaDiRec	GRU4Rec	2.56 ± 0.27	2.54 ± 0.24	2.51 ± 0.23
	TiSASRec	2.55 ± 0.23	2.52 ± 0.24	2.58 ± 0.26

Table 2: Response time comparison between proposed PaDiRec and the "Retrain" approach across
 three datasets using three different backbones. Note that the unit is seconds (sec.).

even with low accuracy weights, and on the Industrial Data, it retains high diversity despite low diversity weights.

5.3 ANALYSES

We conducted our analysis experiments based on three key research questions: **RQ1**: What are the advantages of Diffusion over Hypernetwork in parameter generation? **RQ2**: Is PaDiRec efficient enough to handle real-time changes in preference weights compared to Retrain? **RQ3**: How do different conditioning strategies impact the model's performance? Additionally, we also present some case study in Apprndix A.12.

Regarding RQ1: Diffusion outperforms Hypernetwork in parameter generation.

We conducted experiments to validate the robustness of the parameters generated by PaDiRec (as assumed in Sec. 4). Specifically, we designed three sets of experiments to constructed adapter parameters: "Retrain", "PaDiRec" and "Hypernetwork", where "Hypernetwork" utilizes the MLP to learn the relationship between the preference weight and the optimized adapter parameters.

458

434

443

444 445

446 447

448

449

450

451

452

459 First, we added Gaussian noise of the same mag-460 nitude to all three sets of adapter parameters and measured the resulting fluctuations in NDCG@10 461 and α -NDCG@10. The experiments were repeated 462 multiple times under various preference weights, 463 and the results are shown in Figure 4. We ob-464 served that the parameters generated by PaDiRec 465 exhibited the lowest performance fluctuations, both 466 in terms of accuracy (NDCG@10) and diversity 467 $(\alpha$ -NDCG@10), when subjected to perturbations, 468 which verifies the assumption in Sec. 4. Addi-469 tionally, we compared the similarity (Inverse Eu-470 clidean Distance) between the three sets of parameters and the Retrain parameters. Hypernetwork-471 generated parameters showed slightly higher sim-472 ilarity to the Retrain parameters than those gener-473 ated by Diffusion, with values of 0.3147 ± 0.0184 474

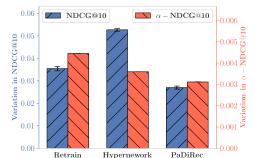

Figure 4: The variation of performance before and after disturbance in MovieLens 1M based on SASRec. The blue bars represent the variation in NDCG@10, while the red represent the variation in α -NDCG@10

and 0.3035 ± 0.0184 , respectively. This indicates that PaDiRec, as a diffusion-based parameter generator, is not merely mimicking parameters but has learned the underlying distribution of parameters, demonstrating its ability to generate robust, high-performance parameters (?).

478 Regarding RQ2: The efficiency and effectiveness of PaDiRec.

PaDiRec is designed to adaptively adjust model parameters in an online environment without retraining, enabling it to quickly respond to new task requirements. This places a strong emphasis
on the model's response time. We compared the response times of PaDiRec and "Retrain" across
various backbones and datasets, with the results shown in Table 2. As observed, in all experiments
using three different backbones across three datasets, PaDiRec's response time was significantly
faster than that of "Retrain". Notably, the response time of "Retrain" correlated with the size of
the dataset, whereas PaDiRec exhibited minimal variation across different datasets. This highlights
PaDiRec's data-agnostic nature indicating its potential for handling large-scale datasets efficiently.

486487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487487<l

We investigate the influence of different conditioning strategies aimed at improving the integra-488 tion of conditions into the denoising model. As shown in Figure 5, each strategy emphasizes dif-489 ferent performance dimensions (details on the construction of each strategy can be found in Ap-490 pendix A.5). In terms of Hypervolume, all five strategies outperform the "Retrain" approach, with 491 the "Pre&Post" strategy achieving the best results. For Pearson r-a and Pearson r-d, the "Adap-492 norm" strategy demonstrates the best overall performance, indicating strong consistency with the 493 "Retrain" approach, i.e., high controllability. Additionally, the Hypervolume remains within an ac-494 ceptable range, suggesting that adding conditions aggregated by an attention mechanism to the layer 495 norm is a promising approach for controllability.

6 RELATED WORK

496 497

498

499 Diffusion models. Diffusion probabilistic mod-500 els (Ho et al., 2020; Song et al., 2020; Nichol & 501 Dhariwal, 2021) have not only achieved significant 502 success in the field of image generation but have 503 also found wide applications in various other ar-504 eas in recent years, such as video generation (Ho 505 et al., 2022b), text generation (Li et al., 2022; Gong et al., 2022), etc. Moreover, diffusion models have 506 shown the ability to generate high-quality neural 507 network parameters, achieving comparable or even 508 superior performance to traditionally trained mod-509 els (Yuan et al., 2024; ?). These models have also 510 been applied to enhance the accuracy of recom-511 mender systems by addressing challenges such as 512 noisy interactions and temporal shifts in user pref-513 erences (Wang et al., 2023). In our work, we utilize 514 diffusion models to generate parameters for con-515 trollable multi-task recommender systems.

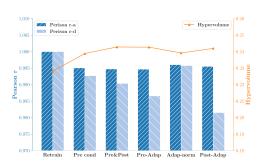

Figure 5: Performances of different conditioning strategies on MovieLens 1M using SASRec as backbone. The results of the "Retrain" algorithm are used as a reference.

516 Multi-task learning (MTL) aims to develop unified models that tackle multiple learning tasks si-517 multaneously while facilitating information sharing (Zhang & Yang, 2021; Ruder, 2017). Recent 518 advancements in MTL include deep networks with various parameter sharing mechanisms (Misra 519 et al., 2016; Long et al., 2017; Yang & Hospedales, 2016) and approaches treating MTL as a multi-520 objective optimization problem (Lin et al., 2019; Mahapatra & Rajan, 2020; Xie et al., 2021). These 521 latter methods focus on identifying Pareto-efficient solutions across tasks, with significant applica-522 tions in recommender systems (Jannach, 2022; Li et al., 2020a; Zheng & Wang, 2022) Researchers 523 have explored different strategies, from alternating optimization of joint loss and individual task weights to framing the process as a reinforcement learning problem (Xie et al., 2021). The emphasis 524 has shifted from optimizing specific preference weights to finding weights that achieve Pareto effi-525 ciency across objectives (Sener & Koltun, 2018; Lin et al., 2019). Some methods utilize attention 526 mechanisms to dynamically allocate computational resources among tasks (Liu et al., 2019). More 527 recent approaches, such as the CMR (?), utilize hypernetworks to learn the entire trade-off curve for 528 MTL problems. However, our novel approach diverges from these existing methods by employing 529 diffusion models to control model parameters at test time, potentially offering greater flexibility and 530 adaptability in handling multi-task learning problems.

531 532

7 CONCLUSIONS

533

This paper addresses the critical challenge of adapting recommendation models to dynamic task requirements in real-world applications, where frequent retraining is impractical due to high computational costs. To tackle this problem, we propose **PaDiRec**, a novel controllable learning approach that enables efficient adaptation of model parameters without retraining by utilizing a diffusion model as a parameter generator. Our approach is model-agnostic, allowing it to integrate with existing recommendation models and enhance their controllability. PaDiRec provides a practical solution for real-time, customizable recommendations in achieving efficient, test-time adaptation.

A.2 SETTINGS OF EXPERIMENT IN DISCUSSION

In this experiment, we conducted tests on MovieLens 1M with preference weights set to $w_i^1 = 0.3$ and $w_i^2 = 0.7$, using SASRec as the backbone. The experiment followed the loss function in Eq. 4. We first trained the adapter to convergence (approximately 30 epochs), then continued training for several more epochs, recording the loss values and adapter parameters after each epoch. Each point in the figure represents a recorded value.

A.3 DATASETS

742 A.3.1 DATASET INTRODUCTION

MovieLens-1M³ contains 1,000,209 anonymous ratings of approximately 3,900 movies, provided by 6,040 users who joined MovieLens in 2000. We sorted each user's browsing history chronologically and filtered out users with fewer than five interactions. As a result, 994,338 interactions, 6,034 users, and 3,125 items were used in the final dataset. Each interaction is formatted to include user ID, item ID, and timestamp. To evaluate the diversity of the recommendation list, we extracted the genre information for each movie from the meta-information. Each movie may belong to one or more of the 18 available genres.

Amazon Grocery and Gourmet Food ⁴ contains 151,254 anonymous reviews of 8,713 products by 14,681 users, spanning from August 09, 2000 to July 23, 2014. Since the items belong to 156 categories, with each item assigned to only one category, we used the GloVe (Pennington et al., 2014) to generate embeddings for each category. We then applied K-means clustering to group them

³https://grouplens.org/datasets/movielens/

⁴http://jmcauley.ucsd.edu/data/amazon/links.html

into 30 broader categories, allowing each item to belong to one or more of these 30 broader genres.
 The interaction format is the same as MovieLens-1M.

The industrial dataset is the user click dataset from a electronics commercial store in , spanning from July 24, 2024, to August 24, 2024. We processed the raw data, filtering out users with fewer than 20 interactions, and randomly selected the interaction histories of 1,000 users. Each interaction was formatted to match the structure used in MovieLens-1M. Notably, the filtered interactions covered several categories. We manually merged similar categories into 27 broader ones, allowing each item to belong to multiple categories, thereby supporting diversity in the dataset.

765 A.3.2 DATASET SETTINGS 766

For the recommendation model setup, we used the ReChorus framework⁵ for standardized processing. Regarding data partitioning strategy, we employed the Leave-One-Out approach. Specifically, for each user's interaction history, interactions were sorted by timestamp, with the last interaction designated as the test set, the second-to-last interaction as the validation set, and the remaining sequence as the training set. During the training stage, negative sampling was set to 9 items per positive interaction, while during testing, the full item set was used.

773 A.4 BASELINES

775 PadiRec was compared with several algorithms that were constructed in the controllable multi-task 776 recommendation scenarios, including: Retraining is performed using Linear Scalarization (Birge 777 & Louveaux, 2011) based on each task description, with the assumption that the resulting model 778 parameters represent the optimal solution. Soup (Wortsman et al., 2022) obtain a new model by av-779 eraging the parameters of fine-tuned models without requiring additional computation during inference. In our work, we fine-tuned two models on accuracy and diversity respectively, and then merged 780 them linearly based on the task description. MMR (Carbonell & Goldstein, 1998) is a heuristic post-781 processing approach with the item selected sequentially according to maximal marginal relevance. 782 We set the hyper-parameters based on the task description to achieve varying degrees of diversity 783 in the recommendations. CMR (Chen et al., 2023) dynamically adjusts models based on prefer-784 ence weights using policy hypernetworks to generate model parameters. LLM (the prompt is shown 785 in A.11) is utilized as a personalized recommender system. We achieve controllable recommen-786 dations by inputting prompts containing specific preference weights to respond to users' real-time 787 preferences. For our experiments, we selected the llama3-7B-Instruct model. Details regarding the 788 prompts and settings can be found in the appendix.

789 790

791

A.5 CONDITION STRATEGIES

Pre Conditioning (i.e., Pre cond.) "Pre" denotes that the preference weights embeddings are integrated into the parameters embeddings before being fed into self-attention layers. In this method, we simply add the preference weight embeddings to the parameters embeddings within the input sequence.

Pre and Post Conditioning (i.e., Pre&Post) "Post" denotes that the preference weights embeddings are intergeted after the parameters embeddings fed into self-attention layers. In this method, we add the preference weights embeddings both "Pre" and "Post".

1134 A.10 NETWORK LAYERS OF RECOMMENDATION MODELS 1135

1136 In our experiments, we implement our framework on three recommendation models, SASRec (Kang & McAuley, 2018), GRU4Rec (Hidasi, 2015), and TiSASRec (Li et al., 2020b). We provide their 1137 details of parameter structure in Tables 4, 5, and 6 respectively. 1138

SASRec (Kang & McAuley, 2018) Self-Attentive Sequential Recommendation. This model em-1139 ploys a Transformer architecture to model user sequences for personalized recommendation tasks. 1140 It utilizes self-attention mechanisms that capture both long and short-term preferences by attending 1141 differently to items based on their relevance. 1142

GRU4Rec (Hidasi, 2015) Gated Recurrent Units for Recommendation Systems. GRU4Rec lever-1143 ages gated recurrent units (GRUs) to model user interaction sequences for session-based recommen-1144 dations. By utilizing a gating mechanism, it effectively captures dependencies across varying time 1145 gaps between interactions, making it robust to session shifts and dropout behaviors. 1146

1147 TiSASRec (Li et al., 2020b) Time Interval-Aware Self-Attention for Sequential Recommendation. 1148 This model extends SASRec by incorporating time intervals between user interactions as an ad-1149 ditional context. TiSASRec modifies the self-attention mechanism to account for these intervals, providing a more nuanced understanding of user preferences that evolve over time. The model 1150 includes a specialized positional encoding scheme to integrate these time dynamics alongside the 1151 sequential user behaviors. 1152

1153 LRURec (Yue et al., 2024) Linear Recurrent Units for Sequential Recommendation. This model 1154 introduces a novel linear recurrent unit architecture tailored for sequential recommendation tasks. LRURec combines the efficiency of recurrent neural networks with the modeling capabilities of 1155 self-attention mechanisms, enabling rapid inference and incremental updates on sequential data. 1156 By decomposing linear recurrence operations and implementing recursive parallelization, LRURec 1157 achieves reduced model size and parallelizable training. 1158

1242 A.11 PROMPT OF LLM IN CONTROLLABLE MULTI-TASK RECOMMENDATION

1244	"You are a recommendation expert who receives a user's chronological purchase history and pro-
1245	vides the next recommended item from a given set of candidate products. " "Please note that you
1246	need to consider the accuracyand diversity of recommendations comprehensively ""Their defini-
1247	tions are as follows: " "Objective 1: Accuracy: Ensure that the recommended items are highly
1248	relevant to the user's interests and needs, thereby ensuring the accuracy of the recommendations.
1249	To measure the effectiveness of your recommendations, it will use nDCG as the evaluation met-
1250	ric. " "Objective 2: Diversity: Ensure that the recommended content is diverse, avoiding exces-
1250	sive recommendations of similar items. To achieve this, it will use Alpha-nDCG as the evaluation
1252	metric, penalizing overly similar recommended items and encouraging a diverse range of content
1252	in the recommendation list. " "Now, I will provide the current user's purchase history and the
	set of candidate products. Purchase history: [-history-]. Candidate product set: [-candidates-]."
1254	"Please rank these candidates and give [-out_num-] item as recommendationns and make them both
1255	diverse and accurately relevant with the history preference. " "To achieve this, consideri the pri-
1256	ority of these two objectives according to the given priority weights (accuracy:[-w_accuracy-] and diversity i], ""Split your output with line break. You MUST reak and output 10 items
1257	diversity: [-w_diversity-]) ""Split your output with line break. You MUST rank and output 10 items as recommendations." "You can not generate candidates that are not in the given candidate set."
1258	as recommendations. Tou can not generate candidates that are not in the given candidate set.

1296 A.12 CASE STUDY

In this section, we present the specific recommendation performance in each set of preference weights. We randomly select one customer from each of the three datasets and demonstrate the performance of the recommendation system models on these individual customers. As the accuracy weight increases (i.e., the diversity weight decreases), we observe a downward trend in the height of the bar chart, indicating that the number of categories represented in the recommendation list decreases, signifying a reduction in diversity. Meanwhile, the line chart shows an upward trend, suggesting that the target item's rank moves higher, reflecting an improvement in recommendation accuracy. The specific details are illustrated in the figures below. These changes clearly demonstrate the effectiveness of the PadiRec algorithm in controllable multi-task recommendation.

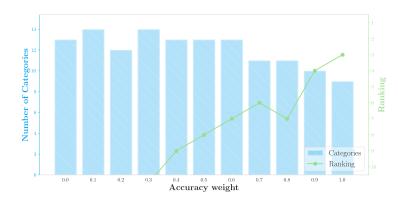

Figure 16: Case study on MovieLens 1M utilizing SASRec as the backbone. Note that the bars represent all the categories contained in the top-10 item list (some lists may contain more than 10 categories, as one item can belong to multiple categories). The line chart represents the rank of the target item in each list.

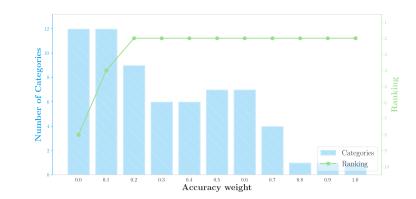

Figure 17: Case study on Amazon FOOD utilizing SASRec as the backbone. Note that the bars represent all the categories contained in the top-10 item list (some lists may contain more than 10 categories, as one item can belong to multiple categories). The line chart represents the rank of the target item in each list.

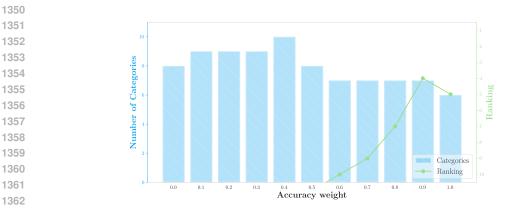

Figure 18: Case study on The industrial dataset utilizing SASRec as the backbone. Note that the bars represent all the categories contained in the top-10 item list (some lists may contain more than 10 categories, as one item can belong to multiple categories). The line chart represents the rank of the target item in each list.

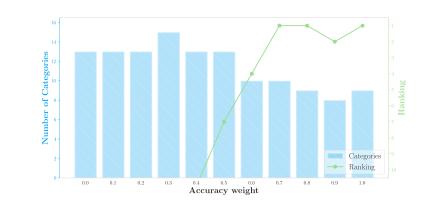

Figure 19: Case study on the MovieLens-1M dataset utilizing GRU4Rec as the backbone. Note that the bars represent all the categories contained in the top-10 item list (some lists may contain more than 10 categories, as one item can belong to multiple categories). The line chart represents the rank of the target item in each list.

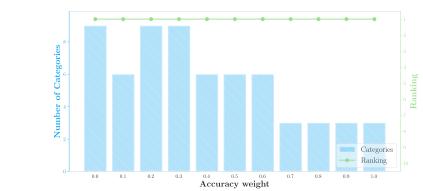

Figure 20: Case study on the Amazon FOOD dataset utilizing GRU4Rec as the backbone. Note that
the bars represent all the categories contained in the top-10 item list (some lists may contain more
than 10 categories, as one item can belong to multiple categories). The line chart represents the rank
of the target item in each list.

The second secon

Figure 21: Case study on the industrial dataset utilizing GRU4Rec as the backbone. Note that the bars represent all the categories contained in the top-10 item list (some lists may contain more than 10 categories, as one item can belong to multiple categories). The line chart represents the rank of the target item in each list.

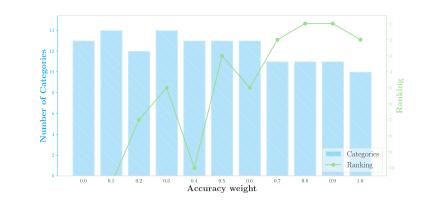

Figure 22: Case study on MovieLens 1M dataset utilizing TiSASRec as the backbone. Note that the bars represent all the categories contained in the top-10 item list (some lists may contain more than 10 categories, as one item can belong to multiple categories). The line chart represents the rank of the target item in each list.

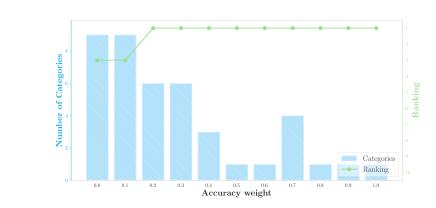

Figure 23: Case study on Amazon FOOD dataset utilizing TiSASRec as the backbone. Note that the bars represent all the categories contained in the top-10 item list (some lists may contain more than 10 categories, as one item can belong to multiple categories). The line chart represents the rank of the target item in each list.

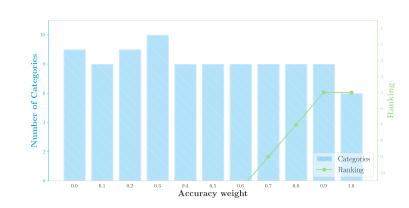

Figure 24: Case study on the industrial dataset utilizing TiSASRec as the backbone. Note that the bars represent all the categories contained in the top-10 item list (some lists may contain more than 10 categories, as one item can belong to multiple categories). The line chart represents the rank of the target item in each list.

Table 7: Case Study of PaDiRec on MovieLens 1M utilizing SASRec as the backbone. We compared the top-10 recommendation lists between an accuracy weight of 0.1 and an accuracy weight of 0.9. Notably, when the accuracy weight is 0.1 (indicating a high preference for diversity), items covering more categories are ranked higher, but the list does not include the target item, indicating poor accuracy. Conversely, with an accuracy weight of 0.9, the target item is ranked in the top 1 position within the recommendation list.

Accuracy	Category	Item	Is Target Item
0.1	Animation, Children's, Comedy, Musical, Romance	Little Mermaid	No
0.1	Action, Comedy, Crime, Horror, Thriller	From Dusk Till Dawn	No
0.1	Adventure, Fantasy, Sci-Fi	Time Bandits	No
0.1	Animation, Children's	Sword in the Stone	No
0.1	Action, Romance, Thriller	Desperado	No
0.1	Adventure, Children's, Fantasy	Santa Claus	No
0.1	Horror, Sci-Fi	Invasion of the Body Snatchers	No
0.1	Film-Noir, Mystery, Thriller	Palmetto	No
0.1	Action, Comedy	Twin Dragons	No
0.1	Film-Noir	Sunset Blvd.	No
0.9	Horror	Birds	Yes
0.9	Drama	Cider House Rules	No
0.9	Comedy, Romance	Annie Hall	No
0.9	Action, Comedy, Crime, Horror, Thriller	From Dusk Till Dawn	No
0.9	Drama, Romance	Girl on the Bridge	No
0.9	Animation, Children's, Comedy, Musical, Romance	Little Mermaid	No
0.9	Comedy	Road Trip	No
0.9	Comedy, Drama	Chuck & Buck	No
0.9	Horror, Sci-Fi	Invasion of the Body Snatchers	No
0.9	Animation, Children's	Sword in the Stone	No

1566 1567	2. Transformer Layer Computation (per layer)
1568	- Innut shanse [197 [19]
1569	• Input shape: [137, 512]
1570	• Self-Attention computation:
1571	Query, Key, Value projections: $3 \times (137 \times 512 \times 512) = 107,479,040$ FLOPs
1572	Attention score computation: $(137 \times 137 \times 64) \times 8 = 12,055,552$ FLOPs
1573	Value weighting: $(137 \times 137 \times 64) \times 8 = 12,055,552$ FLOPs
1574	Output projection: $137 \times 512 \times 512 = 35,826,688$ FLOPs
1575	
1576	• Feed-forward network computation:
1577	First linear layer (512 \rightarrow 2048): $137 \times 512 \times 2048 = 143,065,088$ FLOPs
1578	Second linear layer (2048 \rightarrow 512): 137 \times 2048 \times 512 = 143,065,088 FLOPs
1579 1580	GELU activation: $137 \times 2048 = 280, 576$ FLOPs
1581	
1582	Single Transformer Layer Total: 453, 827, 584 FLOPs
1583	
1584	3. Output Processing
1585	• Final linear projection $(512 \rightarrow 8)$: $137 \times (512 \times 8) = 561, 152$ FLOPs
1586	$(512 \times 6) = 501, 152 + 1013$
1587	A.14.3 TOTAL COMPUTATION
1588	
1589 1590	1. Single Step Computation
1590	
1592	• Initial processing: 1,088,000
1593	• Transformer layers: $453, 827, 584 \times 4 = 1, 815, 310, 336$
1594	• Output processing: 561, 152
1595	• Per step total: 1,816,959,488 FLOPs
1596	
1597	2. Complete Sampling Process (500 steps):
1598 1599	• Total FLOPs: 1,816,959,488 × 500 = 908,479,744,000 \approx 0.9085 TFLOPs
1600	
1601	A.14.4 EFFICIENCY EVALUATION AND CONCLUSION
1602 1603	Taking the RTX 3090 as an example, which achieves 35.58T FLOPS per second, our diffusion
1604	model requires only 0.9085T FLOPs for the entire 500-step sampling process. Therefore, the infer-
1605	ence process of the diffusion model takes approximately 0.026 seconds. Including some data storage
1606	overhead, the total time is around the order of seconds (aligned with Table 2). In real-world recom- mendation scenarios, a single recommendation typically occurs within milliseconds. However, for
1607	users, waiting 2-3 seconds to customize a more personalized model is considered acceptable.
1608	
1609	A.15 DISCUSSION ON USED MOVIELENS EVALUATION
1610	
1611	We utilized the MovieLens dataset for our experiments. MovieLens is among the most widely used
1612	datasets in the recommender systems domain, serving as a standard benchmark for validating new models and ensuring reproducibility. However, it is important to acknowledge that the user-item
1613 1614	interactions recorded in the MovieLens dataset primarily reflect engagements between users and
1614	the MovieLens platform, where users are prompted to recall movies they have previously watched.
1616	This setup differs significantly from typical recommendation scenarios encountered in real-world
1617	applications, as analysis by Fan et al. (2024).
1618	Nonetheless, the MovieLens dataset remains valuable for research purposes. It provides researchers
	with a standardized handbmark facilitating the varification of model implementations and anabling

patterns of sequential data but rather on providing controllability to the backbone models. Therefore, employing the MovieLens dataset in our research is justified. We recognize the limitations of relying solely on the MovieLens dataset. To comprehensively assess the effectiveness and applicability of our model, we conducted experiments on three datasets, further demonstrating the effectiveness of the algorithm.
