Sample Efficiency Matters: Training Multimodal Conversational Recommendation Systems in a Low Resource Setting

Anonymous ACL submission

Abstract

 Multi-modal conversational recommendation (multi-modal CRS) can potentially revolution- ize how customers interact with e-commerce platforms. Yet conversational samples, as train- ing data for such a system, are difficult to ob- tain in large quantities, particularly in new plat- forms. Motivated by this challenge, we con- sider multimodal CRS in a low resource set- ting. Specifically, assuming the availability of a small number of samples with dialog states, we devise an effective dialog state encoder to bridge the semantic gap between conversation and product representations for recommenda- tion. To reduce the cost associated with dia- log state annotation, a semi-supervised learn- ing method is developed to effectively train the dialog state encoder with a smaller set of la- beled conversations. In addition, we design a correlation regularisation that leverages the multi-modal knowledge in the domain database to better align textual and visual modalities. Ex-**periments on two datasets (MMD and SIMMC)** demonstrate the effectiveness of our method. Particularly, with only 5% of the MMD training set, our method (namely SeMANTIC) is com- parable to the state-of-the-art model trained on the full dataset.

⁰²⁸ 1 Introduction

 Over the past few years, there has been a grow- ing interest in conversational recommendation sys- tems (CRS). These systems bring together the user- friendly nature of conversational AI and the busi- ness potential of recommendation systems, poten- tially revolutionizing how customers engage with e- commerce platforms. Unfortunately, conventional text-based dialogue systems have inherent limita- tions in capturing user preferences. In many prac- tical situations, a blend of textual and visual cues allows agents to recommend products that are bet- ter aligned with user interests (e.g., see Figure [1](#page-0-0) for an example).

Figure 1: In a multimodal CRS, a user expresses her/his requirements with preferred example image. The dialog state (belief state) encapsulates user interest across turns and modalities.

The advance in deep learning along with the **042** introduction of multi-modal benchmarks, such as **043** MMD [\(Saha et al.,](#page-10-0) [2018\)](#page-10-0), have contributed signifi- **044** cantly to the recent progress in multi-modal CRS. A **045** number of methods have been developed using Re- **046** current Neural Networks (RNN) [\(Saha et al.,](#page-10-0) [2018\)](#page-10-0), **047** RNN with attention [\(Cui et al.,](#page-8-0) [2019\)](#page-8-0), Graph Neu- **048** ral Networks (GNN) [\(Zhang et al.,](#page-10-1) [2021\)](#page-10-1), Memory **049** Networks [\(Nie et al.,](#page-9-0) [2021\)](#page-9-0), Knowledge-enhanced **050** Convolution Network (CNN) [\(Liao et al.,](#page-9-1) [2018a\)](#page-9-1), **051** and Transformer [\(Ma et al.,](#page-9-2) [2022\)](#page-9-2). Unfortunately, **052** deep learning-based methods require a significant **053** number of sample conversations with relevance 054 annotation (for recommendation), which can be **055** challenging to acquire. For example, the aforemen- **056** tioned methods have been trained on MMD using **057** hundreds of thousands of conversations, and it is **058** unclear whether these approaches remain effective **059** when being trained on a smaller sample size. 060

In this paper, we examine multi-modal CRS in **061** a low resource setting. Specifically, we consider **062** that there are only a limited number of sample con- **063** versations and strive to make the most of the data **064** by following two insights. Firstly, when the num- **065**

 ber of sample conversations is limited, augmenting them with dialog states can help bridge the seman- tic gap between dialogues and products as being shown in traditional text-based task-oriented dia- [l](#page-9-4)og (TOD) systems [\(Lei et al.,](#page-9-3) [2018;](#page-9-3) [Hosseini-Asl](#page-9-4) [et al.,](#page-9-4) [2020;](#page-9-4) [Shu et al.,](#page-10-2) [2018;](#page-10-2) [Zhang et al.,](#page-11-0) [2020b;](#page-11-0) [Yang et al.,](#page-10-3) [2021\)](#page-10-3). Unfortunately, dialog state anno- tation can be time-consuming, especially in multi- modal dialogs. Therefore, we assume that only a subset of sample conversations are annotated with dialog states, and design an effective method for dialog state modeling. Secondly, the vast amount of products with both textual and visual informa- tion should be exploited to bridge the cross-modal semantic gap. Intuitively, doing so helps improve the system's capability in understanding user pref-erences across modalities (see U3, Figure [1\)](#page-0-0).

 With such considerations, we propose a Sam- ple Efficient Multi-modAl coNversaTIonal reCom- mendation system, or SeMANTIC for short. More specifically, dialog contexts and candidate prod- ucts are first encoded with a context encoder and a product encoder separately, resulting in initial con- text/product representations. Such representations are then enhanced with Dialog-State Interaction modules that capture the interactions of the context (or the product) representations with shared dialog state embeddings. By doing so, we leverage dialog states to bridge the semantic gap between the dialog and the product sides. Here, dialog state embed- dings are learned via a teacher-student framework, where the teacher network has access to the limited size of dialogs with belief states, and the student network learns from the teacher to estimate dialog state embeddings from conversations without dia- log states. We then propose a regularization term that makes state-aware (text/visual) representations of the same product closer to each other. By do- ing so, we effectively utilize the large number of products in the domain database for bridging the cross-modal semantic gap.

107 All in all, our main contributions are as follows:

- **108** We propose a novel model, SeMANTIC, that **109** enhances dialog and product representations **110** with dialog states, and a regularization term **111** that leverages the domain database to bridge **112** cross-modal semantic gap.
- **113** A semi-supervised learning is proposed based **114** on the teacher-student framework to allevi-**115** ate the annotation cost associated with dialog **116** state tracking.
- Extensive evaluation on SIMMC and MMD **117** datasets demonstrates the superiority of our **118** model in comparison to strong baselines in a **119** low resource setting. **120**
- Further analysis validates that our semi- **121** supervised learning approach is data efficient **122** as it only requires a small ratio of supervision **123** for learning dialog state embeddings. **124**

2.1 Unimodal Conversational Systems **126**

Traditionally, dialog systems are divided into **127** chitchat and TOD systems. The former improves **128** user engagement, whereas the later helps users fin- **129** ish a specific task such as booking hotels. This **130** categorization helps characterize fundamental sub- **131** tasks such as response generation [\(Wu and Yan,](#page-10-4) **132** [2019;](#page-10-4) [Sun et al.,](#page-10-5) [2020;](#page-10-5) [Chao et al.,](#page-8-1) [2021;](#page-8-1) [Chen](#page-8-2) **133** [et al.,](#page-8-2) [2022\)](#page-8-2), dialog state tracking [\(Yan et al.,](#page-10-6) [2017;](#page-10-6) **134** [Shu et al.,](#page-10-2) [2018;](#page-10-2) [Lei et al.,](#page-9-3) [2018;](#page-9-3) [Song et al.,](#page-10-7) [2021\)](#page-10-7), **135** dialog policy [\(Hosseini-Asl et al.,](#page-9-4) [2020;](#page-9-4) [Kung et al.,](#page-9-5) **136** [2021;](#page-9-5) [Zhao et al.,](#page-11-1) [2022;](#page-11-1) [Yang et al.,](#page-10-3) [2021\)](#page-10-3). **137**

Recently, there is a growing interest in connect- **138** ing conversational agents with external systems, **139** resulting in the introduction of new types of dia- **140** log systems such as CRSs [\(Christakopoulou et al.,](#page-8-3) **141** [2016;](#page-8-3) [Zhang et al.,](#page-11-2) [2018;](#page-11-2) [Sun and Zhang,](#page-10-8) [2018;](#page-10-8) **142** [Zhang et al.,](#page-10-9) [2020a;](#page-10-9) [Hayati et al.,](#page-8-4) [2020;](#page-8-4) [Deng et al.,](#page-8-5) **143** [2021\)](#page-8-5), knowledge-grounded dialog systems [\(Wang](#page-10-10) **144** [et al.,](#page-10-10) [2019;](#page-10-10) [Zhao et al.,](#page-11-3) [2019;](#page-11-3) [Zhou et al.,](#page-11-4) [2020;](#page-11-4) **145** [Liu et al.,](#page-9-6) [2021b\)](#page-9-6). Unlike traditional ones, these 146 systems may contain dialog turns for recommen- **147** dation, knowledge-graph access, or fulltext search. **148** Beside traditional subtasks such as dialog policy **149** [\(Sun and Zhang,](#page-10-8) [2018;](#page-10-8) [Zhang et al.,](#page-10-9) [2020a;](#page-10-9) [Deng](#page-8-5) **150** [et al.,](#page-8-5) [2021\)](#page-8-5), or dialog state tracking [\(Yan et al.,](#page-10-6) **151** [2017;](#page-10-6) [Shu et al.,](#page-10-2) [2018;](#page-10-2) [Lei et al.,](#page-9-3) [2018;](#page-9-3) [Song et al.,](#page-10-7) **152** [2021\)](#page-10-7), new subtasks have been introduced such as **153** [r](#page-11-5)etrieval-augmented response generation [\(Zhang](#page-11-5) **154** [et al.,](#page-11-5) [2020c;](#page-11-5) [Zou et al.,](#page-11-6) [2020;](#page-11-6) [Ren et al.,](#page-10-11) [2021\)](#page-10-11), **155** [d](#page-8-3)ialog-based recommendation [\(Christakopoulou](#page-8-3) **156** [et al.,](#page-8-3) [2016;](#page-8-3) [Zhang et al.,](#page-11-2) [2018;](#page-11-2) [Hayati et al.,](#page-8-4) [2020\)](#page-8-4). **157**

2.2 MultiModal Conversational Systems **158**

The introduction of multi-modal datasets have been **159** introduced to foster studies in multi-modal QA **160** such as VisDial [\(Das et al.,](#page-8-6) [2017\)](#page-8-6), GuessWhat 161 [\(De Vries et al.,](#page-8-7) [2017\)](#page-8-7) and FashionIQ [\(Wu et al.,](#page-10-12) **162** [2021\)](#page-10-12), and multi-modal dialogs [\(Saha et al.,](#page-10-0) [2018;](#page-10-0) **163** [Kottur et al.,](#page-9-7) [2021;](#page-9-7) [Liao et al.,](#page-9-8) [2021\)](#page-9-8). Among **164** these, MMD is the multi-modal dialog dataset in **165**

 retail that comes with high quality images and re- quires cross-modal reasoning. The majority of previous baselines for multi-modal CRS are con- ducted on this dataset [\(Saha et al.,](#page-10-0) [2018;](#page-10-0) [Cui et al.,](#page-8-0) [2019;](#page-8-0) [Nie et al.,](#page-9-9) [2019,](#page-9-9) [2021;](#page-9-0) [Zhang et al.,](#page-10-1) [2021\)](#page-10-1). [Saha et al.](#page-10-0) [\(2018\)](#page-10-0) present a basic multimodal hi- erarchical encoder-decoder model (MHRED) as a first benchmark in the field of multimodal CRS. Since then, attention and research have focused on [d](#page-8-0)eveloping better multimodal CRS models [\(Cui](#page-8-0) [et al.,](#page-8-0) [2019;](#page-8-0) [Nie et al.,](#page-9-9) [2019;](#page-9-9) [He et al.,](#page-8-8) [2020;](#page-8-8) [Liao](#page-9-10) [et al.,](#page-9-10) [2018b\)](#page-9-10). [Cui et al.](#page-8-0) [\(2019\)](#page-8-0) propose a user attention-guided multimodal CRS which is based on MHRED and uses a hierarchical product taxon- [o](#page-9-9)my tree to extract visual features. MAGIC [\(Nie](#page-9-9) [et al.,](#page-9-9) [2019\)](#page-9-9) proposes knowledge-aware RNN to encode dialog context for response generation and product recommendation. [Nie et al.](#page-9-0) [\(2021\)](#page-9-0) intro- duce a contextual image search scheme (LARCH) with multi-form knowledge interactions via mem- ory network. [Zhang et al.](#page-10-1) [\(2021\)](#page-10-1) introduce TREA-**SURE** that represents dialog contexts using graph- based models and incorporate side information such as the product attributes and style-tips from celebrities. And recently, [Ma et al.](#page-9-2) [\(2022\)](#page-9-2) lever- age a unified transformer semantic representation framework with feature alignment and intention reasoning for multi-modal dialog systems.

 Our work also focuses on the e-commerce set- ting proposed by [Saha et al.](#page-10-0) [\(2018\)](#page-10-0) but targets the unexplored problem of learning with a limited num- ber of conversations. In addition, our investigation is on the recommendation task, which remains a challenging subtask in multi-modal CRS, particu- larly now that response generation can be greatly improved with large language models. Note that this is also in line with the recent studies such as [\(Nie et al.,](#page-9-0) [2021;](#page-9-0) [Zhang et al.,](#page-10-1) [2021\)](#page-10-1).

204 2.3 Learning in a Low-Resource Setting

 Deep learning has been the mainstream approach recently. Unfortunately, deep learning methods are also data hungry, requiring a large amount of training conversational samples with annota- tion. For example, to train a task-oriented dialog (TOD) system, we need conversations that are fully annotated with dialog states and system actions [\(Budzianowski et al.,](#page-8-9) [2018\)](#page-8-9). For conversational recommendation, it is also needed to collect di- verse dialog samples annotated with recommen- [d](#page-8-9)ations and various user requests [\(Budzianowski](#page-8-9) [et al.,](#page-8-9) [2018;](#page-8-9) [Li et al.,](#page-9-11) [2018;](#page-9-11) [Liu et al.,](#page-9-12) [2020\)](#page-9-12).

As labeled data is difficult to obtain, it is desir- **217** able to develop data efficient methods based on pre- **218** trained models [\(Yang et al.,](#page-10-13) [2023;](#page-10-13) [He et al.,](#page-8-10) [2022\)](#page-8-10), **219** meta-learning [\(Dai et al.,](#page-8-11) [2020\)](#page-8-11), or semi-supervised **220** [l](#page-9-14)earning [\(Yang et al.,](#page-10-14) [2022;](#page-10-14) [Huang et al.,](#page-9-13) [2020;](#page-9-13) [Li](#page-9-14) **221** [et al.,](#page-9-14) [2020\)](#page-9-14). Specifically, [Yang et al.](#page-10-13) [\(2023\)](#page-10-13) and **222** [Hu et al.](#page-9-15) [\(2022\)](#page-9-15) leverage pretrained language mod- **223** els and prompt learning for dialog state tracking in **224** TOD. [Dai et al.](#page-8-11) [\(2020\)](#page-8-11) target fast adaptability of **225** TOD dialog systems to domains with low-resource **226** data using meta-learning. [Zhao et al.](#page-11-7) [\(2020\)](#page-11-7) and **227** [Liu et al.](#page-9-16) [\(2021a\)](#page-9-16) decompose response generation **228** in knowledge-grounded dialog systems into dis- **229** entangled decoders, each can be pretrained with **230** unlabeled data. Semi-supervised learning has been **231** used to utilize unlabeled data for estimating ac- **232** tion embeddings in task-oriented dialog systems **233** [\(Huang et al.,](#page-9-13) [2020\)](#page-9-13), dialog state tracking [\(Zhang](#page-11-0) **234** [et al.,](#page-11-0) [2020b\)](#page-11-0), or grounded sentences in knowledge- **235** grounded dialog systems [\(Li et al.,](#page-9-14) [2020\)](#page-9-14). **236**

Our work also follows the semi-supervised learn- **237** ing approach but focuses on multi-modal dialogs **238** instead of unimodal dialogs. It is noteworthy that **239** we cannot simply adopt a unimodal method to a **240** multi-modal scenario. For instance, one simple **241** way to apply these available methods [\(Huang et al.,](#page-9-13) **242** [2020;](#page-9-13) [Zhang et al.,](#page-11-0) [2020b\)](#page-11-0) to our task is to consider **243** DST as a text sequence generation task. However, **244** as we empirically show in Section [5.3,](#page-7-0) without **245** careful consideration of the semantic gap between **246** modalities as well as between products and dialogs, **247** even gold (sequentialized) DST will not facilitate **248** the recommendation task. **249**

3 METHODOLOGY **²⁵⁰**

We study the problem of training CRSs with a small **251** number of samples. Formally, let \mathcal{D}_F be the set of 252 *M* fully labeled dialogues $\tau_i = \{u_t | 1 \le t \le n_{\tau_i}\}$ where u_t indicates the t-th turn from either the user 254 or the agent. Each (user or agent) utterance u_t 255 contains the textual part u_t^T and the visual part u_t^T i.e. a list of user uploaded images or system rec- **257** ommended product images. For t-th user turn, we **258** are provided with a dialog state s_t^T that summa- 259 rizes the user requests throughout the conversation. **260** Additionally, let \mathcal{D}_P be the set of partially labeled 261 dialogs of which we do not have dialog state annota- **262** tion. We assume that \mathcal{D}_P is larger in size compared 263 to \mathcal{D}_F , but still in a moderate size. The CRS task 264 is formalized as selecting products from a domain **265** database $P = \{(\rho_k^T, \rho_k^I)|1 \le k \le n_P\}$ as response 266

}, **253**

, **256**

267 to a user request. Here, a product in P is associated 268 with both textual description ρ_k^T and images ρ_k^I .

 The overall architecture of SeMANTIC is de- picted in Figure [2,](#page-4-0) where the main idea is to treat dialog states as shared (continuous) variables that bridge the semantic gaps between the textual modality and the visual modality, and between the conversation and the product sides. Specifically, representations of user texts/images and product texts/images are both enhanced with dialog state embeddings using Dialog State Interaction (DSI) modules (Section 3.2). Here, the dialog state em- beddings are obtained by encoding the groundtruth 280 dialog states for those in \mathcal{D}_F , and inferred by the dialog learner for those in the partially labeled set **(Section 4).** To mitigate the limited size of \mathcal{D}_F , we add a regularization term inferred from the partially 284 labeled dialogs \mathcal{D}_P and the abundance of products in P (section 3.4 and 4).

286 3.1 Context and Product Encoders

 Context Encoder Let τ be a dialog context and $u_t^T = \{w_{t1}, w_{t2}, \dots, w_{tn_t^T}\}\$ be the textual utter-289 ance at the t-th turn, where w_{t_i} is an one-hot repre- sentation of the i-th word, we obtain the turn-level text representation as follows:

292
\n
$$
U_{ti}^T = w_{ti}W_{emb} + PE(i)
$$
\n293
\n
$$
U_t^T = [U_{t1}^T, ..., U_{tn_t}^T]
$$
\n294
\n
$$
\mathbf{v}_t^T = SumPool[SelfAttn(U_t^T, U_t^T, U_t^T)]
$$

 where Wemb is the word embeddings obtained from BERT [\(Devlin et al.,](#page-8-12) [2018\)](#page-8-12), PE and SelfAttn denote [t](#page-10-15)he position embedding and self-attention [\(Vaswani](#page-10-15) [et al.,](#page-10-15) [2017\)](#page-10-15). The dialog-level representation for the textual modality is as follows:

300
$$
V^{T} = [\mathbf{v}_{1}^{T}, ..., \mathbf{v}_{n_{\tau}}^{T}]
$$

$$
C^{T} = SelfAttn(V^{T}, V^{T}, V^{T})
$$

302 Similarly, we construct the turn-level vi-**303** sual representation from the t-th turn 304 $u_t^I = \{I_{t1}, I_{t2}, \ldots, I_{tn_t^I}\}$:

$$
U_{ti}^I = ResNet(I_{ti})
$$

\n
$$
v_t^I = SumPooling[U_{t1}^I, ..., U_{tn_t}^I]
$$

\n
$$
V^I = [v_1^I, ..., v_{n_\tau}^I]
$$

\n
$$
C^I = CrossAttn(C^T, V^I, V^I)
$$

309 The final dialog representations c^T and c^I (for the **310** textual and visual modalities) are attained from the 311 **last turn representations in** C^T **and** C^I **.**

Product Encoder The product text ρ^T and visual 312 ρ^I representations for a product $\rho_l = (\rho_l^T, \rho_l^I)$ are 313 obtained similarly to the turn-level dialog represen- **314** tations (i.e. v_t^T and v_t^I). Note also that the low-level 315 image representation ResNet are shared between **316** the context encoder and the product encoder. **317**

3.2 Dialogue State Interaction Module **318**

Our objective is to exploit dialog states for bridg- **319** ing the semantic gaps in multi-modal CRS. As **320** such, we first get a dialog state embedding $S_0 \in$ 321 $R^{n_{state} \times n_{dim}}$ from the context (see Section 4 for 322 more details). Inspired by Memory Networks **323** [\(Sukhbaatar et al.,](#page-10-16) [2015\)](#page-10-16), we then introduce Di- **324** alog State Interaction (DSI) modules to enhance **325** both dialog and product representations with infor- **326** mation in dialog states. **327**

The general architecture of Dialog State Inter- **328** action (DSI) module is depicted in Figure [2](#page-4-0) with **329** K layers of multi-hop interactions. Given an input 330 vector x_k and a state embedding matrix S_k , the 331 outputs of the k-th layer are obtained: **332**

$$
S_{k+1} = W_{k+1} S_k \tag{333}
$$

$$
a_{k+1,i} = \frac{\cos(x_k, S_{k,i})}{\sum_{j}^{n_{state}} \cos(x_k, S_{k,j})}
$$

$$
x_{k+1} = x_k + \sum_{i}^{n_{state}} a_{k+1,i} S_{k+1,i}
$$

where W_{k+1} denotes the model parameters and a_{k+1} corresponds to the attention score vector. Note that x_0 is obtained from a context or prod uct encoder (e.g. c^T , or p^T) and S_0 is from the state encoder module.

3.3 Recommendation **341**

Given a dialog τ and a candidate product ρ , the 342 relevance score is measured as follows: **343**

$$
f(\tau,\rho) = \tanh[\cos(x^{CT}, x^{PT}) + \cos(x^{CI}, x^{PI})]
$$

where $x^{CT}, x^{CI}, x^{PT}, x^{PI}$ are extracted from the 345 last layers of DSI modules, and correspond to state- **346** enhanced representations for the dialog context and **347** the candidate product. **348**

3.4 Training **349**

To train SeMANTIC, we construct a training set **350** $\{(\tau_i, \rho_{ii}^+, \ldots, \rho_{in_{pos}}^+, \rho_{i1}^-, \ldots, \rho_{in_{neg}}^-\})\}$ by sampling 351 dialog contexts and the gold image responses from 352 \mathcal{D}_P . Here, τ_i indicates one conversation context, $\qquad \qquad$ 353

Figure 2: The overall architecture of SeMANTIC (left). Here, Dialog State Interaction (DSI) modules of the same color are shared between the dialog product sides. The details of a DSI module is shown on the right block.

354 whereas ρ_{ij}^+ and ρ_{ik}^- denote a positive recommen- dation and a (sample) negative recommendation for the i-th context. Note also that the dialog state encoder is trained jointly with the rest of the model. However, we postpone the detailed discussion un- til Section 4, where semi-supervised learning for dialog state modeling is described.

 Ranking Loss The main objective for training SeMANTIC is to maximize the margin in the rel- evance score of the positive product compared to the negative product. In other words, we minimize the following rank loss:

$$
366 \qquad \mathcal{L}_{rk} = max(0, 1 - f(\tau, \rho^+) + f(\tau, \rho^-))
$$

367 where the loss is measured for a sample triple 368 (τ, ρ^+, ρ^-) . Here, we drop the context and product **369** indices for simplicity.

 Jensen Shannon Divergence To better align the context and the product representations, we mea- sure Jensen-Shannon divergence [\(Menéndez et al.,](#page-9-17) [1997\)](#page-9-17) between the attention vectors extracted from the last layer of DSI (Equation [3.2](#page-3-0) for $k = K$). **Specifically, we respectively obtain** (a^{CT}, a^{CI}) for **the context text and images, and** (a^{PT}, a^{PI}) **for the** product text and images, then measure:

$$
g(\tau, \rho) = JS(a^{CT}, a^{PT}) + JS(a^{PI}, a^{PI})
$$

 Intuitively, we would like the g score to be small for **the relevant pair** (τ, ρ^+) and larger for the irrelevant **pair** (τ, ρ^-) . To achieve this, we incorporate the following loss to the objective function:

$$
2_{JS} = max(0, g(\tau, \rho^+) - g(\tau, \rho^-))
$$

384 Correlation Similarity Due to the limited size **385** of conversational samples, we rely on the larger **386** number of available products to bridge the gap

Figure 3: The Teacher (left) vs The Student State Encoder (right).

between the textual and visual modalities. Our goal **387** is to minimize the regularization term calculated **388** for a given product ρ as follows: 389

$$
\mathcal{L}_{co-sim}(\rho) = max(0, 1 - \cos(x^{PT}, x^{PI})) \tag{39}
$$

The idea here is make the (text/visual) state- **391** enhanced representations of the same product **392** closer to each other. **393**

Overall Finally, the overall loss function \mathcal{L}_{all} is: 394

$$
\sum_{i} \left\{ \mathcal{L}_{rk} + \mathcal{L}_{JS} + \sum_{\rho_{ik}^{\pm}} \mathcal{L}_{co-sim}(\rho_{ik}^{\pm}) \right\}
$$
 395

where ρ_{ik}^{\pm} indicates either a positive or negative 396 sample associated with the context τ_i . . **397**

4 Semi-supervised State Learning **³⁹⁸**

To leverage small samples with dialog states, we **399** follow the teacher-student framework [\(Chen et al.,](#page-8-13) **400** [2017\)](#page-8-13), where the teacher and student have a similar **401** structure but differ in the dialog state encoder. **402**

409 color or type. For each slot key such as color, the **410** slot value is "none" if it is not mentioned in the 411 dialog context τ_t , and a specific value (e.g. red)

 Teacher State Encoder The teacher has access 404 to the ground truth dialog state in \mathcal{D}_F , where each **dialog state** $u^S = \left[(u_i^{SK}, u_i^{SV}) | 1 \le i \le n_{state} \right]$ is a list of slot and value pairs. The slot keys are 407 drawn from a predefined set of n_{state} product prop-erties defined in the domain database P, such as

 $S_i = S_i^{K} + S_i^{V}$

 $S = SelfAttn(S, S, S)$

 $\overline{C} = C^T + C^I$

 $\widetilde{S} = S^K + \widetilde{S}^V$

the "State Learner" as follows:

443 \mathcal{D}_F . All in all the joint training objective is:

 $\sqrt{ }$

 $\alpha \mathcal{L}^{tea}_{all} + (1 - \alpha)$

412 otherwise. For the i-th slot, we treat the slot key **413** and value as strings and attain the key and value

414 **embeddings** $S_i^K \in R^{1 \times n_d}$, $S_i^V \in R^{1 \times n_d}$ via BERT **415** and MeanPooling, which is similar to the text en-**416** coder in Section 3.1. The state embedding is then

417 obtained via self attention as follows:

418

419 $S = [S_1, ..., S_{n_{state}}]$

$$
^{420}
$$

421 Student State Encoder The student network es-

422 timates the slot value embedding from the con-**423** text information by employing a "Value Predictor".

424 Specifically, we first obtain the key embedding 425 $S^K \in R^{n_{state} \times n_d}$ for all slot keys similarly to that

426 in the teacher state encoder. The value embedding **427** are then calculated as follows:

428

429 $\widetilde{S}^V = CrossAttn(S^K, \bar{C}, \bar{C})$

430 where CrossAttn is the cross attention operator. We

431 then obtain the predicted state embedding \tilde{S} using
432 the "State Learner" as follows:

433

 $\widetilde{S} = SelfAttn(\widetilde{S}, \widetilde{S}, \widetilde{S})$

435 Joint Training We train the teacher network on 436 \mathcal{D}_F and the student network on $\mathcal{D}_F + \mathcal{D}_P$ using the

437 **loss function** \mathcal{L}_{all} **as in Section 3.4. Hereafter, we**

438 refer to the teacher and the student training losses

439 **as** \mathcal{L}_{all}^{tea} **and** \mathcal{L}_{all}^{stu} **. We then let the teacher network 440** to guide the student network by minimizing the

441 mean square error of groundtruth dialog state em-**442** beddings and the predicted state embeddings on

 $\alpha \mathcal{L}_{all}^{con} + (1 - \alpha) \left[\mathcal{L}_{all}^{sea} + \sum_i MSE(S_i, S_i) \right]$

445 where S_i , S_i are the outputs of the teacher and **446** student encoders, respectively.

 $\mathcal{L}^{stu}_{all} + \sum$

 $\tau_i \in \mathcal{D}_F$

 $MSE(S_i, S_i)$

5 Experiments **⁴⁴⁷**

Evaluation Datasets Experiments are conducted **448** [o](#page-9-7)n MMD [\(Saha et al.,](#page-10-0) [2018\)](#page-10-0) and SIMMC [\(Kottur](#page-9-7) **449** [et al.,](#page-9-7) [2021\)](#page-9-7). The MMD dataset contains more than **450** 150k conversations in retail domain. Following pre- **451** vious works [\(Nie et al.,](#page-9-0) [2021;](#page-9-0) [Zhang et al.,](#page-10-1) [2021\)](#page-10-1), **452** we adopt the updated MMD dataset constructed **453** by Nie [\(Nie et al.,](#page-9-0) [2021\)](#page-9-0) and refer to it as MMD- **454** v2, which is divided into training/validation/test **455** sets with ratio 70%/15%/15%. To study the impact **456** of the sample size and dialog states, we sample **457** around 5% of MMD-v2 and perform dialog state **458** annotation with slot keys being product attributes. **459** We refer to this set of MMD as MMD-v3. We 460 split the data to sets train/valid/test so that the train- 461 ing/valid/test set of MMD-v3 is a subset of the **462** corresponding set of MMD-v2. As for SIMMC, **463** the dataset contains 10681 scene based conversa- **464** tions, which is divided into 68% for training, 16% **465** for validation, and 16% for testing. We extend the **466** multimodal coreference resolution task into a rec- **467** ommendation task by utilizing bounding boxes to **468** extract product objects from the same scene. **469**

Implementation Details We implement our pro- 470 posed model using PyTorch^{[1](#page-5-0)} and conduct our ex- **471** periments on 1 NVIDIA V100 GPU with a mini- **472** batch size 64 and 50 epochs. The dimension of **473** the initial word embedding is set to 768, and the **474** dimension of the initial image embedding is set to **475** 512. The dimensions of both context representation **476** and product representation are set to 768. For each **477** experimental setting, the results from multiple runs **478** of SeMANTIC and the baselines are averaged. **479**

Evaluation Metrics Following [\(Nie et al.,](#page-9-0) [2021;](#page-9-0) **480** [Zhang et al.,](#page-10-1) [2021\)](#page-10-1), Precision@k, Recall@k, and **481** NDCG@k for $(k=5, 10, \text{ and } 20)$ are the adopted 482 metrics for the recommendation task in CRS. **483**

Compared Methods We compare SeMANTIC **484** to baselines with published codes including **485** MHRED [\(Saha et al.,](#page-10-0) [2018\)](#page-10-0), UMD [\(Cui et al.,](#page-8-0) **486** [2019\)](#page-8-0), MAGIC [\(Nie et al.,](#page-9-9) [2019\)](#page-9-9), LARCH [\(Nie](#page-9-0) **487** [et al.,](#page-9-0) [2021\)](#page-9-0), and TREASURE [\(Zhang et al.,](#page-10-1) [2021\)](#page-10-1). **488**

5.1 Main Results **489**

We present the evaluation results on SIMMC, and **490** MMD in Table [1.](#page-6-0) Note that on MMD, all com- **491** pared models are trained on MMD-v3 but tested **492** on MMD-v3 or MMD-v2. In addition, we consider **493**

Table 1: The overall results of SeMANTIC and baselines, in which the average and standard deviations of different runs are reported. MMD v3/ v2 (or MMD v3/ v3) means we train the model on the training set of MMD-v3 and evaluate on the testing set of MMD-v2 (or MMD-v3). TREASURE† is both trained and tested on MMD-v2 and reported from [\(Zhang et al.,](#page-10-1) [2021\)](#page-10-1).

Figure 4: Performance of SeMANTIC trained with varying ratio of fully labeled data on MMD-v3.

494 100% supervision for SeMANTIC here, leaving **495** semisupervised learning analysis to next section.

 Table [1](#page-6-0) presents the experimental results, where a number of observations can be drawn. Firstly, SeMANTIC outperforms the compared methods on SIMMC and two testing sets of MMD, par- tially validating its effectiveness and generaliza- tion. Secondly, while the unified memory network in LARCH may help bridge semantic gaps across modalities as well as between the conversation and product sides, the method may be too complex to train effectively with a small sample size. As a result, LARCH falls short compared to simpler methods like MHRED, MAGIC, and TREASURE, despite being the second best-performing method when being trained with the MMD-v2 training set [\(Nie et al.,](#page-9-0) [2021\)](#page-9-0). And finally, even though we train our method with MMD-v3, which is only 5% of the training set of TREASURE† (MMD-v2), the evaluation results on the test set of MMD-v2 show

Figure 5: Performance of SeMANTIC trained with varying sample sizes on MMD-v2.

that our method is comparable to TREASURE†. **514** It should be noted that training on MMD-v2 is **515** time-consuming, thereby preventing us from train- **516** ing compared models multiple times for compari- **517** son. Consequently, we directly report the results of **518** TREASURE † from [\(Zhang et al.,](#page-10-1) [2021\)](#page-10-1). **519**

5.2 The Impacts of Sample Size **520**

To verify the effectiveness of semi-supervised state **521** learning, we conduct experiments on MMD-v3 and **522** change the ratio of the sizes of \mathcal{D}_F to \mathcal{D}_P . For 523 every epoch, we first jointly train both teacher and **524** student models on \mathcal{D}_F , then train the student model 525 on D^P without considering ground-truth dialogue **⁵²⁶** state. Figure [4](#page-6-1) indicates that our model improves **527** as more annotated data is utilized. Furthermore, **528** the reduction in standard deviation indicates that **529** the model's performance becomes more stable as **530** more samples with labeled states are considered. 531 More importantly, our model's performance with **532**

7

Figure 6: The impacts of dialog states.

533 20% of the supervision ratio is nearly as good as **534** having full supervision to learn state embeddings.

 We evaluate the impact of the number of train- ing (conversational) samples by conducting experi-537 ments on MMD-v2. Specifically, we keep \mathcal{D}_F to be **MMD-v3** training set, and increase the set \mathcal{D}_P to in- clude more samples from the training set of MMD- v2. The results of SeMANTIC and TREASURE are then reported on the testing set of MMD-v2 in Figure [5.](#page-6-2) The results show that SeMANTIC out- performs TREASURE in terms of NDCG@5 when 544 the size of \mathcal{D}_P to be around 10% of the MMD-v2, validating the sample efficiency of SeMANTIC.

546 5.3 Can Baselines Benefit from Dialog States?

 SeMANTIC exploits dialog states during training, but this information is not available in baselines. As a result, we study whether the incorporation of dialog states into baselines can help improve performance of such methods. As adapting the baselines to incorporate dialog state prediction is nontrivial, we directly consider ground truth dialog states as part of the dialog input for the baselines during both training and testing. This experiment is carried out on MMD-v3^{[2](#page-7-1)}, where there exists dialog state annotation for conversations in both the training and testing sets. For SeMANTIC (w/o DS), state encoding excludes slot values during training, making it fair to compare with the baselines (w/o DS). Note that SeMANTIC (w/ DS) only exploits groundtruth values during training.

 The performance comparison between the base- lines and SeMANTIC with and without dialog states is presented in Figure [6.](#page-7-2) Among all the methods, only LARCH and SeMANTIC show im- provement on NDCG@k (k=5,10, 20) when dialog states are considered. One possible explanation is that the slot values in dialogue states may not match product attribute values. As a result, only LARCH, which leverages diverse interactions be-tween dialogs and knowledge through multi-form

Figure 7: Effect of different loss functions.

knowledge modeling, and SeMANTIC, which in- **573** corporates correlation similarity, can make good **574** use of dialog state information. **575**

5.4 Ablation Study **576**

To examine the contributions of different loss func- **577** tions, we exclude MSE loss (w/o MSE), correla- **578** tion similarity loss (w/o co_sim), or JS divergence **579** (w/o JS) from the training objective. **580**

Figure [7](#page-7-3) showcases the impact of different loss 581 types on SeMANTIC in terms of three metrics **582** on MMD-v3. The results reveal several findings. **583** Firstly, the extraction of hidden information from **584** text-image correlation in products (co_sim) plays **585** a vital role in enhancing the model's performance. **586** Secondly, the use of MSE loss as guidance for **587** the student model is also essential, given that the **588** model's performance declines without this infor- **589** mation, especially at lower ranks ($R@5$, $R@10$). 590 Thirdly, the incorporation of \mathcal{L}_{JS} helps reducing 591 variation, making the model more stable. **592**

6 CONCLUSION AND FUTURE WORK **⁵⁹³**

In this paper, we present a novel approach named **594** SeMANTIC for multimodal conversational recom- **595** mendation systems (CRS). To bridge the gap be- **596** tween dialogs and products, we propose dialog **597** state interaction modules to enhance both the di- **598** alog and the product sides with dialog states. To **599** overcome the challenge of collecting dialogue state **600** labels, we develop a state value predictor to learn **601** the dialog state embedding following a teacher- **602** student framework. In addition, we introduce a **603** correlation regularization for semantic alignment **604** on the abundant products in the domain database. **605** Our comprehensive experiments demonstrate the **606** superiority of our proposed approach in the recom- **607** mendation task when compared to existing meth- **608** ods. In the future, active learning-based methods **609** [\(Liu et al.,](#page-9-18) [2019;](#page-9-18) [Sinha et al.,](#page-10-17) [2019\)](#page-10-17) can be studied **610** to improve sample efficiency for multimodal CRS. **611**

⁶¹² Limitations

 Due to time and computational constraints, our study did not consider the approach based on large vision-language models, such as [\(Radford et al.,](#page-10-18) [2021;](#page-10-18) [Li et al.,](#page-9-19) [2023;](#page-9-19) [Zhao et al.,](#page-11-8) [2023;](#page-11-8) [Wang et al.,](#page-10-19) [2022\)](#page-10-19). These models have shown promising results in various tasks, including semantic alignment and understanding in multimodal settings.

 In the future, we plan to investigate how to adapt these large vision-language models to our domain- specific database and explore their potential as base models for semantic alignment and recommenda- tion in our multimodal conversational recommen- dation system. This would involve addressing chal- lenges related to model scalability, computational resources, and fine-tuning on domain-specific data.

 By incorporating these advanced models, we aim to further enhance the performance and capabili- ties of our system, leveraging the rich information present in both textual and visual modalities.

988 A Appendix

989 A.1 Dataset Statistics

990 In this paper, we conduct extensive experiments **991** on two well-known datasets, namely MMD and

Dataset		MMDv2	MMD v3 with DS			
Dataset Stats	Train	Valid	Test	Train	Valid	Test
Dialogs	105439	22595	22595	5478	1113	1174
Proportion	70%	15%	15%	72%	14%	14%
Avg Rec Turns				6	6	6
Avg Pos Imgs		4		4	4	4
Avg Neg Imgs	616	618	994	628	632	989

Table 2: Statistics of the dataset by [\(Nie et al.,](#page-9-9) [2019\)](#page-9-9) (MMD v2) and the subset with dialogue state annotation (MMD v3 with DS).

Dataset	SIMMC					
Dataset Stats	Train	Valid	Test			
Dialogs	7307	1687	1687			
Proportion	68%	16%	16%			
Avg Rec Turns						
Avg Pos Imgs	2	\overline{c}	\mathfrak{D}			
Avg Neg Imgs	22	22	フフ			

Table 3: Statistics of the SIMMC dataset.

SIMMC. For further insights, detailed statistics are **992** provided in Tabl[e2](#page-11-9) and Tabl[e3](#page-11-10) respectively. Here, **993** "Avg Rec Turns" indicates the average number of **994** recommendations per dialog; and "Avg Pos Imgs" **995** denotes the number of correct recommendations **996** per turn whereas "Avg Neg Imgs" is the number of **997** distractors for evaluation. **998**

A.2 Implementation Details **999**

We implement our proposed model using Py-
1000 Torch library ^{[3](#page-11-11)} and conduct our experiments on **1001** 1 NVIDIA V100 GPU with a mini-batch size 64 **1002** and 50 epochs. Adam [\(Kingma and Ba,](#page-9-20) [2014\)](#page-9-20) is **1003** adopted as the optimizer, with the initial learning **1004** rate 5×10^{-4} and the linear learning rate sched- 1005 uler [\(Goyal et al.,](#page-8-14) [2017\)](#page-8-14) is used. Additionally, the 1006 dimension of the initial word embedding is set to **1007** 768, and the dimension of the initial image embed- **1008** ding is set to 512. The dimension of both context 1009 representation and product representation are set **1010** to 768. The number of layers of all transformer **1011** based encoders and decoders are set to 3, the num- **1012** ber of attention heads in the multi-head attention **1013** is 8 and the inner-layer size is 768. We set all 1014 dropout rate to 0.1 [\(Srivastava et al.,](#page-10-20) [2014\)](#page-10-20), and α 1015 to 0.5 (Section 4). Moreover, we use 5 turns prior **1016** to the current turn as the context with the maximum **1017** sentence length of 30 and the maximum number 1018 of historical images to 5. It is worth mentioning **1019** that although both $\mathcal{L}_{all}^{teacher}$ and $\mathcal{L}_{all}^{student}$ contain 1020 \mathcal{L}_{JS} and \mathcal{L}_{co-sim} , such losses are calculated by 1021 the teacher model and deactivated by the student **1022** model on \mathcal{D}_F . These losses are only activated for **1023** the student model on \mathcal{D}_P . 1024

SeMANTIC	31.99 ± 0.33	$87.14 + 0.71$	$76.82 + 0.87$	17.85 ± 0.09	95.45 ± 0.41	$79.96 + 0.75$	$9.35 + 0.01$	98.99 ± 0.14	$81.04 + 0.64$

Table 4: Effect of different loss functions.

Param α	R@5	R@10	R@20
$\alpha = 0.1$	$73.57 + 1.59$	$74.81 + 1.64$	$75.85 + 1.55$
$\alpha = 0.3$	74.04 ± 1.64	$75.27 + 1.69$	$76.22 + 1.67$
$\alpha = 0.5$	$75.87 + 0.71$	$76.94 + 0.72$	$77.91 + 0.71$
$\alpha = 0.7$	$75.65 + 1.71$	76.77±1.79	$77.74 + 1.73$
$\alpha = 0.9$	75.69 ± 0.78	76.91 ± 0.61	77.84 ± 0.60

Table 5: The results with different α on MMD v3.

Figure 8: The impacts of dialog states on SIMMC.

 For baseline methods, we adhere to a standard- ized approach which adopts the default configura- tions as set in the original papers. By doing so, we ensure a consistent and accurate comparison with the established methodology.

1030 A.3 Supplementary Material

1031 A.3.1 Ablation Study

1032 We further extend the ablation study to SIMMC **1033** dataset and Table [4](#page-12-0) showcases more details of the **1034** impact of different loss types on SeMANTIC.

1035 A.3.2 Effect of Hyper-parameter α

1036 **To study the effect of hyper-parameter** α , we did 1037 **several experiments with different** α **on MMD/ v3.** 1038 The results with different α are given in Tabl[e5,](#page-12-1) 1039 which shows that our method is not sensitive to α .

1040 A.3.3 Effect of Dialog States on SIMMC

 As mentioned in Section5.3, to study whether the incorporation of dialog states into baselines can help improve performance of such methods, we did experiments on MMD-v3. Here, we further extend the experiments to SIMMC, and the results are provided in Figur[e8.](#page-12-2)

1047 A.4 Ethics and Broader Impacts

 Our work is conducted using simulated data (pub- [l](#page-10-1)ished datasets), similar to previous studies [\(Zhang](#page-10-1) [et al.,](#page-10-1) [2021;](#page-10-1) [Saha et al.,](#page-10-0) [2018;](#page-10-0) [Cui et al.,](#page-8-0) [2019;](#page-8-0) [Nie](#page-9-0) [et al.,](#page-9-0) [2021,](#page-9-0) [2019\)](#page-9-9), and does not involve the use of

any user-sensitive information. The purpose of our **1052** research is to develop and evaluate a multimodal **1053** conversational recommendation system in a low **1054** resource setting. **1055**

We recommend following data protection guide- 1056 lines and regulations when applying our method 1057 in real platforms. It is crucial to obtain user agree- **1058** ments and informed consent before analyzing user **1059** requests or engaging in any data collection activ- **1060** ities. This can be achieved through agree-upon **1061** interviews, and perform data simulation instead of **1062** using real conversations. **1063**
