005 **Anonymous authors**

006 Paper under double-blind review

## 009 ABSTRACT

011 Prompt tuning, especially perturbation-based prompt tuning, encounters obstacles  
 012 in visual generation. On the one hand, the autoregressive paradigm, which pro-  
 013 vides the most ideal environment for prompt tuning, struggles to model planar  
 014 concept: traditional autoregressive methods employ raster-scan for image model-  
 015 ing, disrupting the spatial structure of images. On the other hand, perturbation-  
 016 based prompts work as learnable perturbations in pixel space, and their effective-  
 017 ness comes at quite a little computational cost, making it difficult to balance per-  
 018 formance and efficiency. To address these challenges, we propose Multi-scale Vi-  
 019 sual Prompt (MVP), a perturbation-based prompt tuning method tailored for visual  
 020 autoregressive generation with planar concept and efficient information propaga-  
 021 tion. MVP builds on Visual AutoRegressive (VAR) models with next-scale predic-  
 022 tion for capturing planar concept, and introduces prompt tokens in the outermost  
 023 token frame at each scale for efficient signal control and information propaga-  
 024 tion. During training, we use increasingly detailed tuning text to facilitate prompt  
 025 learning. Moreover, MVP extends VAR’s capability for text-to-image generation.  
 026 Extensive experiments validate the effectiveness of MVP. Code is [available](#).

## 027 1 INTRODUCTION

029 Prompt tuning (Li & Liang, 2021; Liu et al., 2021; Lester et al., 2021) enables models to per-  
 030 form specific tasks by introducing the learnable prompt, requiring only minimal fine-tuning without  
 031 any access to model parameters. In generation tasks, particularly in textual generation based on  
 032 large language models (LLMs), prompt tuning has achieved remarkable success (Hao et al., 2023;  
 033 Ajwani et al., 2024; Tang et al., 2022). However, its transfer to visual generation has not reached the  
 034 same success. Although some embedding-based (Gal et al., 2022; Ruiz et al., 2023) and adapter-  
 035 based (Yeh et al., 2023; Ye et al., 2023) prompt tuning methods show notable results in visual gen-  
 036 eration, perturbation-based prompt tuning, which offers stronger controllability and is more suitable  
 037 for high-dimensional tasks, remains almost unexplored. We identify the following two reasons:

038 *First, traditional autoregressive methods cannot model planar concept.* The autoregressive  
 039 paradigm inherently provide an ideal environment for perturbation-based prompt tuning, as they can  
 040 seamlessly incorporate the learnable prompt: prompt and input within autoregressive models share  
 041 the same structure, enabling prompt and input tokens to be directly concatenated or added without  
 042 requiring architectural adjustments or additional modules. Moreover, the autoregressive paradigm  
 043 also ensures full-coverage prompt control: serving as contextual information, prompt participates  
 044 in attention computations across all layers and heads, and their influence progressively propagates  
 045 through autoregressive modeling. In contrast to the diffusion paradigm (Sohl-Dickstein et al., 2015;  
 046 Ho et al., 2020) requiring thousands of conditional inputs, autoregressive minimizes prompt signal  
 047 attenuation. Therefore, the autoregressive paradigm serves as the foundation for perturbation-based  
 048 prompt tuning. However, traditional autoregressive modeling converts visual content into a sequence  
 049 in raster-scan order, limiting the model’s ability to capture original spatial adjacency relationships  
 050 and two-dimensional structural correlations, ultimately leading to outputs lacking global consist-  
 051 ency and suboptimal performance compared to other visual generation paradigms. The emergence  
 052 of Visual AutoRegressive (VAR) (Tian et al., 2024) addresses this deficiency by transforming the  
 053 autoregressive modeling pattern from next-token prediction into next-scale prediction. In next-scale  
 prediction, each prediction unit contains a scale-specific feature map, which is a set of multiple  
 tokens predicted simultaneously rather than sequentially. This modeling pattern preserves the spa-

utilization tokenizer. Inspired by residual quantization methods (Lee et al., 2022; Huijben et al., 2024), VAR (Tian et al., 2024) reframes next-token prediction as next-scale prediction, further unleashing the potential of the autoregressive paradigm to generate high-quality visual content. The emergence of autoregressive methods based on next-scale prediction (Zhang et al., 2024a; Tang et al., 2024; Han et al., 2025; Qu et al., 2025) reflects increased optimism about the future development of visual autoregressive generation. Therefore, we develop a simple yet efficient perturbation-based prompt tuning on the VAR family with next-scale prediction to enhance task performance.

### 3 METHODOLOGY

The overall framework of MVP is illustrated in Figure 1. MVP utilize a set of tokens located in the outermost square frame at each scale to introduce the learnable prompt, which is square frame prompt. As the scale increases, the computational cost of square frame prompt grows rapidly. Therefore, we establish a scale threshold beyond which the number of square frame prompt tokens no longer increases with scale increase, presenting as one square frame prompt transforming into four L-shaped prompts at one scale. The prompt tokens are directly added with the input tokens. In training, we adopt a CLIP to encode multiple tuning texts (sentence and caption) and certain feature maps for contrastive learning to enable MVP learning.

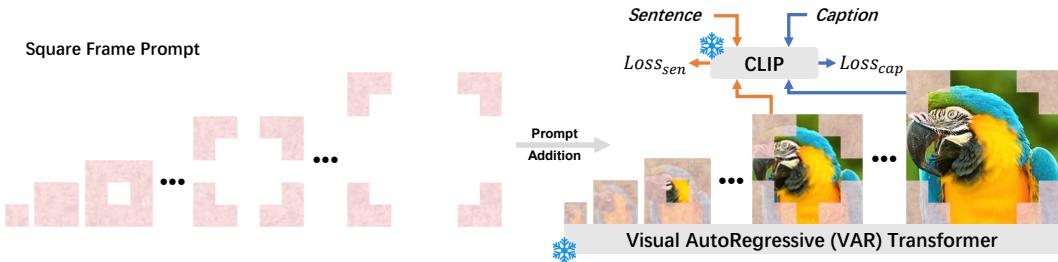

Figure 1: The Overall framework of MVP.

#### 3.1 PROMPT DESIGN PRINCIPLE

##### 3.1.1 MODEL SELECTION

As discussed in the previous section, it is ideal for MVP to possess planar concept. VAR (Tian et al., 2024) and VAR-like models (Tang et al., 2024; Han et al., 2025) based on next-scale prediction serve as the target models for MVP. By decomposing generation into next-scale residual feature map prediction, VAR naturally introduces two components: an intra-scale residual feature map, representing the spatial plane, and an coarse-to-fine inter-scale sequence, reflecting the temporal progression across scales. The modeling process of VAR involves  $T$  multi-scale token feature maps  $(R_1, R_2, \dots, R_T)$  defined by a size set  $\{S_1 \times S_1, S_2 \times S_2, \dots, S_T \times S_T\}$ . At the  $t$ -th scale, VAR predicts the residual feature map  $R_t \in \mathbb{R}^{S_t \times S_t}$  based on all previous scales. The autoregressive likelihood can be formulated as follows:

$$p(R_1, R_2, \dots, R_T) = \prod_{t=1}^T p(R_t \mid \langle \text{sos} \rangle, R_1, R_2, \dots, R_{t-1}), \quad (1)$$

where  $(R_1, R_2, \dots, R_{t-1})$  denotes the "prefix" of  $R_t$ , and  $\langle \text{sos} \rangle$  is the conditional embedding.

##### 3.1.2 CENTRAL IMPACT ANALYSIS

After determining the target model, we consider the form of prompt introduction. Research (Zhang et al., 2024b) reveals that although prompt tuning can effectively enhance the performance of models, it may also result in limited performance improvement or significant degradation for other tasks. This is attributed to the fact that the learnable prompt leads to notable changes in the model's visual features, consequently invalidating plenty of knowledge acquired from large-scale pre-training during its transfer to other models, thus impacting their performance. This phenomenon, referred to as model feature corruption, critically impairs overall model performance.

In addition, perturbation-based prompt tuning carries higher feature corruption risks, as it directly introduces perturbation within the pixel space. Therefore, it is essential to employ an appropriate form of prompt introduction to resist image corruptions. In some visual tasks, the methods (Bahng et al., 2022; Wu et al., 2022; Xie et al., 2023) introduce control signals in the pixel space around clean images as a frame, ensuring minimal impact on the image center. The image center typically contains critical information and primary objects. Modifying the image center may cause issues such as subject deformation, semantic drift, and expression distortion, thereby affecting subsequent image-text alignment, understanding, and generation.

Taking the feature map  $R_t \in \mathbb{R}^{S_t \times S_t}$  at the  $t$ -th scale as an example, we divide  $R_t$  into  $N + 1$  concentric square frames by layers. Specifically, Frame 0 is the outermost frame, containing all tokens on the outermost boundary. Frame 1 is the sub-outermost frame, with its tokens positioned just inside Frame 0, forming a second boundary. Following this pattern, Frame N is the center frame, containing the innermost token(s), where  $N = \left\lfloor \frac{\min(S_t)}{2} \right\rfloor$ . We denote the set of tokens in Frame  $n$  as  $\mathcal{S}_{t,n}$ , for  $n = 0, 1, \dots, N$ . Signals (i.e., perturbations) weaken as the propagation distance increases. In maps with hierarchical structure or spatial layout, the impact received by nodes diminishes with increasing distance from the source. Therefore, we define the propagation distance as  $dis$  and the signal attenuation factor  $\alpha$  related to propagation distance, where the attenuation factor is negatively correlated with propagation distance:  $dis \propto -\alpha$ . If a perturbation  $\delta$  is added to a token in frame  $n$ , then its impact  $I_n$  on the center frame  $\mathcal{S}_{t,N}$  is:  $\text{Impact}(n \rightarrow N) = \delta \cdot \alpha_{N-n}$ . Therefore, the impact of introduction from outermost frame 0 and non-outermost frame  $c$  on the center frame can be denoted as  $I_0 = \delta \cdot \alpha_{N-0}$  and  $I_c = \delta \cdot \alpha_{N-c}$ . Since  $N - 0 > N - c$ , therefore  $I_0 < I_c$ .

Through both qualitative and quantitative analyses, we demonstrate that introducing prompts in the outermost square frame minimizes impact on the image center, thereby avoiding model feature corruption. Therefore, we propose that MVP incorporates the learnable prompt within the outermost square frame of the feature map at each scale.

### 3.1.3 OVERALL IMPACT ANALYSIS

Introducing the prompt in the outermost square frame ensures minimal impact on the center of images while resisting image corruptions. Meanwhile, the form of token introduction is supposed to achieve good overall propagation efficiency, meaning that prompt tokens are distributed within a reasonable and appropriate proximity to each input token, thereby facilitating input tokens receiving signal control and information propagation from prompt tokens. Therefore, we analyze the overall impact of the outermost square frame prompt introduction across the entire feature map.

For the feature map  $R_t \in \mathbb{R}^{S_t \times S_t}$  at the  $t$ -th scale, we define the index set of all tokens at this scale as  $\Omega_t = \{(x, y) \mid x, y \in \{1, 2, \dots, S_t\}\}$ . Therefore, the token index set of the outermost square frame is  $\mathcal{B}_t = \{(x, y) \in \Omega_t : (x \in \{1, S_t\}) \vee (y \in \{1, S_t\})\}$ . Thus, the minimum distance from any token to the outermost square frame can be represented as follow:

$$dis_{\min}((x, y), \mathcal{B}_t) = \min_{(u, v) \in \mathcal{B}_t} \|(x, y) - (u, v)\|, \quad (2)$$

where the distance can be measured using Manhattan distance, Euclidean distance, Chebyshev distance, or other suitable metrics.

Given that the linear distances between the given token and the prompt tokens located on the same row or column correspond to the minimum distances to the four outermost boundaries, it follows:

$$dis_{\min}((x, y), \mathcal{B}_t) = \min\{x - 1, S_t - x, y - 1, S_t - y\}. \quad (3)$$

We define the unified maximum distance  $dis_{\max}^{\text{uni}}$  from any token to the outermost square frame as:

$$dis_{\max}^{\text{uni}} := \max_{(x, y) \in \Omega_t} dis_{\min}((x, y), \mathcal{B}_t). \quad (4)$$

From Equation 3, it can be observed that the token(s) at the geometric center is/are farthest from the outermost square frame, thus  $dis_{\max}^{\text{uni}} = \lfloor (S_t - 1)/2 \rfloor$ .

Given that  $dis_{\max}^{\text{uni}}$  is less than half the scale size  $\frac{S_t}{2}$ , it can be demonstrated that introducing the prompt in the outermost square frame also achieves a good overall propagation efficiency.

### 3.2 MULTI-SCALE VISUAL PROMPT

Following the prompt design principles described above, MVP introduces learnable prompts in the outermost square frames of feature maps in VAR family models based on next-scale prediction.

#### 3.2.1 PROMPT TOKEN SELECTION

For the feature map  $R_t \in \mathbb{R}^{S_t \times S_t}$  at the  $t$ -th scale, MVP selects prompt tokens in the outermost square frame of  $R_t$ . The number of these prompt tokens at the  $t$ -th scale is represented as  $N^{\mathcal{B}_t}$  and is given by  $N^{\mathcal{B}_t} = \mathcal{I}_{\text{id}}^{\mathcal{B}_t} = 4S_t - 4$ , where  $\mathcal{I}_{\text{id}}^{\mathcal{B}_t}$  is the index set of prompt token positions in the outermost square frame of the feature map  $R_t$ . Therefore, the prompt token set  $\mathcal{V}^{\mathcal{B}_t}$  of the square frame prompt with dimension  $D$  can be represented as follow:

$$\mathcal{V}^{\mathcal{B}_t} = [\mathbf{v}_t^1, \dots, \mathbf{v}_t^{N^{\mathcal{B}_t}}] \in \mathbb{R}^{N^{\mathcal{B}_t} \times D}. \quad (5)$$

In VAR, the number of tokens grows rapidly from small to large scales, which can rapidly increase computational cost, against the original intention of prompt tuning. Although the square frame prompt design has effectively reduced the prompt computational budget from  $\mathcal{O}(S^2)$  to  $\mathcal{O}(S)$ , the number of square frame prompt tokens still becomes pretty large as the scale increases, requiring more computational cost. Therefore, we set a threshold  $\tau$  on the number of square frame prompt tokens to preserve efficiency when the scale is large. Specifically,  $\tau$  is the maximum number of square frame prompt tokens. Once the threshold  $\tau$  is exceeded, the number of prompt tokens for the scale remains constant. Formally, a square frame prompt is converted into four L-shaped prompts: four corner tokens of the feature map outward along the outermost square frame, incorporating  $a$  tokens in every available direction. These combined tokens collectively form the L-shaped prompts.  $a = \lfloor (\tau - 4)/8 \rfloor$ , thus  $N^{\mathcal{B}_t} = 8a + 4$ . Update the square frame prompt set  $\mathcal{V}^{\mathcal{B}_t} = [\mathbf{v}_t^1, \dots, \mathbf{v}_t^{N^{\mathcal{B}_t}}]$ .

#### 3.2.2 PROMPT TOKEN ADDITION

For the  $t$ -th scale, we utilize the square frame prompt set  $\mathcal{V}^{\mathcal{B}_t}$  to construct the prompt feature map  $\mathcal{F}_t \in \mathbb{R}^{S_t \times S_t \times D}$  that matches the shape of the feature map  $R_t$ . All non-prompt positions in  $\mathcal{F}_t$  are padded with zeros. Then, we add  $\mathcal{F}_{t+1}$  to  $R_{t+1}$  to obtain the new feature map  $\hat{R}_t$  at the  $t+1$ -th scale:  $\hat{R}_{t+1} = R_t + \mathcal{F}_{t+1} \in \mathbb{R}^{S_t \times S_t \times D}$ . And the autoregressive likelihood can be reformulated as:

$$p(R_1, \dots, R_T) = \prod_{t=1}^T p(R_t \mid \langle \text{sos} \rangle, \hat{R}_1, \dots, \hat{R}_{t-1}, \mathcal{F}_t). \quad (6)$$

### 3.3 PROMPT LEARNING STRATEGY

Although perturbation-based prompt tuning works in pixel space and can effectively control style, texture, spatial layout, and other visual elements to improve visual generation, they have weaker semantic controllability than embedding-based and adapter-based prompt tuning. Taking embedding-based prompt tuning as an example, it incorporates semantically rich embedding vectors into the feature space, thereby establishing connections with semantic representation. In contrast, perturbation-based prompt tuning essentially introduces learnable perturbation, which exhibits poor interpretability and lacks semantics, resulting in suboptimal semantic expression. Moreover, since VAR is a class-to-image generation model, its class-level conditioning inherently lacks rich semantic information, making the training of perturbation-based prompts significantly challenging.

The above analysis indicates that incorporating richer semantic information is the key to training perturbation-based prompts, allowing prompts to acquire more essential knowledge. It is worth noting that the feature map scales predicted by VAR based on next-scale prediction gradually increase, we suppose that different stages of this coarse-to-fine generation process require different tuning texts. Early stages focus on modeling semantic concept, so class-level text (label) works well for prompt learning. Middle stages refine concept and layout, making sentence-level text suitable. Later

270 stages enhance details, so caption-level text with more details helps prompts learn richer semantics.  
 271 Therefore, we propose multi-level semantic refinement as a strategy to improve prompt training.  
 272

273 Specifically, we introduce two more tuning texts: a sentence-level text  $\mathcal{T}_{\text{sen}}$  containing relatively  
 274 comprehensive concepts (using fixed templates such as “a photo of {}”), and a caption-level text  
 275  $\mathcal{T}_{\text{cap}}$  containing detailed visual attributes and fine-grained semantic information. These tuning texts  
 276 with difference granularity facilitate MVP to fine-tune VAR, thereby enhancing VAR’s semantic  
 277 expression and generation quality.  $K$  is the total number of VAR scales. We set an inter-anchor  
 278 index  $\kappa = \lfloor \beta K \rfloor \in \{1, 2, \dots, K-1\}$  with a hyper-parameter  $\beta \in (0, 1)$  (e.g.  $\beta = 0.6$  found  
 279 by grid search). Based on this anchor, we employ the image  $\mathcal{I}_{\text{sen}}$  at the  $\kappa$ -th scale and the image  
 280  $\mathcal{I}_{\text{cap}}$   $K$ -th scale to enable the prompt to learn from sentence-level and caption-level tuning text,  
 281 respectively.  $\mathcal{I}_{\text{sen}}$  and  $\mathcal{I}_{\text{cap}}$  are generated by following processes:

$$\mathcal{I}_{\text{sen}} = \text{Decoder}\left(\sum_{t=1}^{\kappa} \text{Up}(R_t)\right), \quad \mathcal{I}_{\text{cap}} = \text{Decoder}\left(\sum_{t=1}^K \text{Up}(R_t)\right), \quad (7)$$

285 where  $R_t$  denotes the residual feature map predicted at the  $t$ -th scale, and  $\text{Up}(\cdot)$  denotes the up-  
 286 sample inversion transform function to unify the spatial shapes.

287 We then apply the CLIP-based loss Radford et al. (2021) to supervise semantic alignment between  
 288 the generated inversion images and their corresponding tuning texts in a shared embedding space.  
 289 Following the standard contrastive learning, we define an image-to-text contrastive loss  $\mathcal{L}_{\mathcal{IT}}$  and a  
 290 text-to-image contrastive loss  $\mathcal{L}_{\mathcal{T}I}$ , and combine them symmetrically as the final CLIP loss  $\mathcal{L}_{\text{CLIP}}$ .  
 291 We apply this loss at both the sentence and caption levels, obtaining the total semantic loss:

$$\mathcal{L}_{\text{semantic}} = \lambda_{\text{sen}} \mathcal{L}_{\text{CLIP}}(\mathcal{I}_{\text{sen}}, \mathcal{T}_{\text{sen}}) + \lambda_{\text{cap}} \mathcal{L}_{\text{CLIP}}(\mathcal{I}_{\text{cap}}, \mathcal{T}_{\text{cap}}), \quad (8)$$

294 where  $\lambda_{\text{sen}}$  and  $\lambda_{\text{cap}}$  are used to balance losses of two levels. This design encourages the prompt to  
 295 incrementally learn richer semantics, enhancing the performance of prompt tuning. The overall loss  
 296  $\mathcal{L}$  combines autoregressive cross-entropy loss  $\mathcal{L}_{\text{autoregressive}}$  and semantic alignment loss  $\mathcal{L}_{\text{semantic}}$ :

$$\mathcal{L} = \mathcal{L}_{\text{autoregressive}} + \mathcal{L}_{\text{semantic}}. \quad (9)$$

## 4 EXPERIMENT

### 4.1 EXPERIMENT SETTINGS

303 **Datasets** Based on ImageNet (Krizhevsky et al., 2017), we construct a multi-level tuning text  
 304 dataset to support multi-level semantic refinement. Sentence-level text: a fixed template, “a photo  
 305 of {class\\_name}”, is used to provide relatively comprehensive semantics across the 1000 categories.  
 306 Caption-level text: detailed captions generated by BLIP-2 (Li et al., 2023a) provide fine-grained  
 307 visual attributes and semantic information. Furthermore, to assess the transferability and generality  
 308 of MVP, we conduct additional experiments on Food101 (Bossard et al., 2014), RESISC45 (Cheng  
 309 et al., 2017), SUN397 (Sun et al., 2023), and MS-COCO (Lin et al., 2014).

310 **Implementation Details** We implement MVP on VAR with 16, 20, 24, 30, 36 layers and follow  
 311 the experimental settings of VAR. For ablation and analysis, we also transfer MVP to other VAR-like  
 312 models such as HART (Tang et al., 2024) and Infinity (Han et al., 2025). The AdamW (Loshchilov &  
 313 Hutter, 2017) optimizer is employed for training. Notably, for class-to-image generation, we discard  
 314 the first-scale prompt to prevent interference with class embeddings. All evaluations are conducted  
 315 on a single NVIDIA A100 GPU with 80 GB of memory. Appendix D includes more details.

### 4.2 MAIN RESULTS

319 **Improve VAR’s Class-to-Image Generation Quality** We evaluate MVP on VAR with depths of  
 320 16, 20, 24, and 30 to generate  $256 \times 256$  images on ImageNet. Table 1 presents a comprehensive  
 321 comparison between MVP, VAR, and other types of generation models. As observed, compared  
 322 to VAR, MVP introduces only minimal parameters while achieving improvements in FID and IS,  
 323 even with some showing marked improvements. For example, MVP reduces FID by 5% compared to  
 VAR-d30. In comparison with other types of generation models, MVP also maintains the advantages

of VAR while further extending its lead, achieving notable performance gains while training only less than 1% of the parameters. Moreover, we also employ MVP at the depth of 36 for image generation at a higher resolution of  $512 \times 512$  on ImageNet. As shown in Table 2, MVP also surpasses VAR as well as other types of generation models.

Table 1: Comparisons on class-to-image generation on ImageNet. Evaluation metrics include Fréchet Inception Distance (FID), Inception Score (IS) and inference time (s). Precision and recall jointly assess the fidelity–diversity trade-off of generated images. The suffix ‘-re’ denotes rejection sampling. ‘ $\downarrow$ ’ and ‘ $\uparrow$ ’ indicate that lower or higher values are preferable.

**Expand Text-to-Image Generation Capability** Since MVP extends the text-to-image generation capability of VAR, we compare MVP with VAR-CLIP (Zhang et al., 2024a), a fully pre-trained method targeting the same extension task. In addition, to explore the superiority of the perturbation-based MVP, we also compare it with LoRA, an adapter-based parameter-efficient fine-tuning method. As shown in Tab. 3, MVP achieves an excellent trade-off between generation quality and training efficiency. Specifically, MVP requires only 0.46% of the training parameters and 0.54% of the training time of VAR-CLIP, while maintaining a competitive FID and surpassing VAR-CLIP

378 in CLIP-Score. Meanwhile, compared with LoRA, MVP also achieves overall superiority in both efficiency and performance. This highlights that MVP is a simple yet efficient prompt tuning method.  
 379  
 380

### 385 4.3 ANALYSIS & ABLATIONS

386  
 387 **Multi-scale Prompt vs. Prefilled Prompt** We evaluate MVP against the traditional pre-filled  
 388 prompt on class-to-image generation to compare the advantages between embedding-based and  
 389 perturbation-based prompt tuning. All experiments are conducted with the 16-depth VAR back-  
 390 bone, with the scale threshold  $\tau$  fixed at 20 and the same number of visual prompt tokens. As shown  
 391 in Table 4, while both methods improve the generation quality, MVP achieves better FID and IS  
 392 than the pre-filled prompt. Moreover, our fine-tuning process incurs lower memory overhead, as our  
 393 strategy avoids increasing the token sequence length.  
 394  
 395

396 **Effect of Prompt Position** To validate the  
 397 effectiveness of our prompt position design  
 398 in MVP, which injects prompts at outermost  
 399 square frame of feature maps, we compare it  
 400 with four alternative position designs with an  
 401 identical prompt token budget: (i) Random:  
 402 Prompt tokens are randomly placed across the  
 403 feature map; (ii) Innermost: Prompt tokens are  
 404 first placed at the center of the feature map (the  
 405 innermost square frame) and then expand out-  
 406 ward until the prompt token budget is reached;  
 407 (iii) Center-to-Outer: Prompt tokens are placed  
 408 starting from the innermost frame, then skip-  
 409 ping one frame before placing the next frame  
 410 of prompt tokens, and so on, forming concen-  
 411 tric prompt frames across the feature map. (iv)

412 Sub-Outermost: Prompt tokens are placed from the second outermost square frame and extend  
 413 outward if the prompt budget is not yet filled. All alternative position designs maintain an equal  
 414 prompt token budget and are tested on VAR backbones with different depths (d16 and d30) for  
 415 class-conditional generation. For fair comparison and to reduce randomness effects, the Random  
 416 Placement variant is repeated three times with different random seeds, and the averaged results are  
 417 reported. As summarized in Table 5, the outermost square frame strategy consistently outperforms  
 418 other strategies, indicating that our prompt position design minimizes distributional distortion of the  
 419 pretrained models while providing effective semantic guidance.

420 **Effect of First-scale Prompt** We examine the impact  
 421 of introducing the visual prompt at the first scale. As  
 422 shown in Table 6, introducing the prompt at the first scale  
 423 significantly degrades class-to-image performance, espe-  
 424 cially in terms of IS, indicating disruption to the VAR  
 425 backbone’s learned class embeddings. In contrast, first-  
 426 scale prompting improves text-to-image generation, fa-  
 427 cilitating alignment between text and class embeddings.

428 **Effect of Threshold  $\tau$**  To determine a suitable scale threshold for MVP, we conduct ablation  
 429 studies on VAR backbones with depth 16, 20, 24 and 30. As shown in Tab. 7, appropriate thresholds  
 430 can achieve a good balance: they provide sufficient prompt capacity to improve FID and IS, while  
 431 avoiding the redundancy and instability that occur with too small or overly large thresholds.

397 Table 5: Performance across different prompt position  
 398 designs on class-conditional generation. “\*” indicates  
 399 mean results over 3 runs with different random seeds.

VAR (MVP)	0.17	<b>29.72</b>	<b>22.42</b>	<b>28.76</b>	<b>37.97</b>

**Comparison with Other PEFT Methods** To evaluate the transferability and generality of MVP across different data distributions, we compare MVP with LoRA and QLoRA on additional datasets: SUN397, RESISC45 and Food101. All experiments are conducted on VAR-d24 with a single epoch of fine-tuning. As shown in Table 8, MVP achieves superior performance to other PEFT methods such as LoRA and QLoRA, while using fewer trainable parameters. Notably, MVP demonstrates a clear advantage under significant domain shifts, such as on the RESISC dataset. These results highlight MVP as an efficient and robust parameter-efficient tuning strategy.

Figure 2: Visualization of class-to-image samples generated use MVP. The first two rows show results at 256 $\times$ 256 resolution, and the third row shows results at 512 $\times$ 512 resolution.

#### 4.4 VISUALIZATION

**Class-to-Image Generation** In Figure 2, randomly selected samples on ImageNet show that MVP generates images with high visual fidelity and diversity. More visualization is provided in Appendix.

**Text-to-Image Generation** As shown in Figure 3, visualization of text-to-image generation (24 depths, 26 GPU-Hours, a single 80G A100) demonstrates that MVP effectively enhances text-image alignment, expanding VAR’s text-to-image generation capability. Notably, both MVP and VAR-CLIP are built upon the same VAR backbones: while VAR-CLIP (depth=16) requires full pretraining with 4782 GPU-Hours on 48 A100 80GB GPUs, MVP attains competitive performance with less than 1% of its computational cost. Moreover, this efficiency advantage is consistently preserved even when applied to a deeper backbone, highlighting the practicality of our fine-tuning strategy.

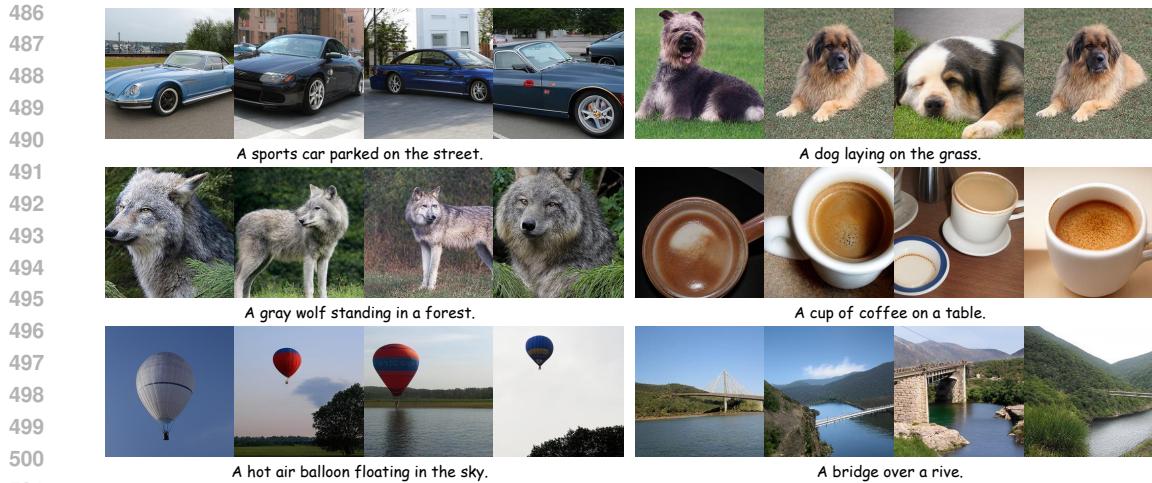

Figure 3: Visualization of text-to-image generation samples at 256×256 resolution using MVP.

## 5 CONCLUSION

In this paper, we propose MVP, a multi-scale visual prompt method with planar concept and efficient information propagation tailored to VAR. By introducing prompt in the outermost square frame and increasingly detailed tuning text, MVP enables effective prompt learning of rich semantics and task features at a relatively low computational cost. Moreover, MVP not only significantly improves performance on the class-to-image generation, but also extends VAR’s text-to-image generation capability. This offers a novel and promising direction for visual autoregressive generation.

## ETHICS STATEMENT

This study is conducted exclusively on publicly available benchmark datasets (ImageNet, Food101, RESISC45, SUN397, and MS-COCO), which are widely adopted in the computer vision research community. These datasets contain no personally identifiable information or sensitive data. The proposed methods focus on achieving class-conditional and text-to-image generation within these benchmarks through perturbation-based prompt design. However, we do not foresee direct negative societal impacts, but acknowledge that generative models may be misused for producing misleading or harmful content. We encourage responsible usage of our models and provide detailed descriptions of implementation and training settings in the appendix to support reproducibility and transparency. This research adheres to the ICLR Code of Ethics.

## REPRODUCIBILITY STATEMENT

We have taken extensive measures to ensure the reproducibility of our results. The model architecture and implementation details are provided in Section 4.1 of the main text, while comprehensive training configurations and hyperparameter settings are described in Appendix D. All datasets used in our experiments are publicly available. In addition, we provide an anonymous supplementary link to our source code, which includes the full training and inference scripts, to further facilitate independent verification of our findings.
