Abstract

While clients may join federated learning to improve performance on data they rarely observe locally, they often remain self-interested, expecting the global model to perform well on their own data. This motivates an objective that ensures all clients achieve a similar *loss gap*—the difference in performance between the global model and the best model they could train using only their local data. To this end, we propose EAGLE, a novel federated learning algorithm that explicitly regularizes the global model to minimize disparities in loss gaps across clients. Our approach is particularly effective in heterogeneous settings, where the optimal local models of the clients may be misaligned. Unlike existing methods that encourage loss parity, potentially degrading performance for many clients, EAGLE targets fairness in relative improvements. We provide theoretical convergence guarantees for EAGLE under non-convex loss functions, and characterize how its iterates perform relative to the standard federated learning objective using a novel heterogeneity measure. Empirically, we demonstrate that EAGLE reduces the disparity in loss gaps among clients by prioritizing those furthest from their local optimal loss, while maintaining competitive utility in both convex and non-convex cases compared to strong baselines.

1 INTRODUCTION

Federated learning enables the training of machine learning models based on data stored across multiple

clients without accessing or sharing it directly (McMahan et al., 2017). It has emerged as a promising training framework for applications with regulated data access such as healthcare (Long et al., 2020), banking (Rieke et al., 2020) and other sensitive applications (Li et al., 2020a). Federated learning is typically orchestrated by a centralized, often trusted server responsible for aggregating local client models and synchronizing updates. This is the setting we consider in our work.

Federated optimization algorithms typically aim to minimize a (weighted) average of the local client training losses by generating a sequence of models based on information received from the clients, such as the gradient of the loss function on their respective data. Clients participate in federated learning by contributing their resources in exchange for access to knowledge aggregated from other clients, enabling the training of a model that generalizes well to the overall data distribution. However, they often also expect the model to perform well on their own local data distribution. For example, consider a medical diagnosis system in which each hospital seeks a model that generalizes to rare or unseen patient cases, while still maintaining high performance on the types of patients commonly encountered in its region. In this context, a model that exhibits uneven performance across datasets from different hospitals can be viewed as unfair. In fact, Federated Averaging (FedAvg)—introduced by McMahan et al. (2017) and now the default algorithm in federated learning—often rewards clients that possess larger datasets, regardless of the relevance of their data to the overall utility. This happens because these clients are (i) typically weighted by their data size during aggregation; and (ii) allowed to run more local steps, since with a fixed batch size larger datasets require more updates per epoch (Wang et al., 2020), steering the global optimization toward their minimizers. These factors raise concerns about unfairness toward other clients, potentially discouraging their participation. As a result, promoting fairness has become a fundamental requirement in federated learning.

Figure 1: In this example, we use the *AFL* algorithm to enforce loss parity between the two clients, and our approach, *EAGLE*, to enforce loss gap parity. Enforcing loss parity favors *client 1*, which has noisier data and a more complex prediction task, resulting in poorer performance for *client 0*. In contrast, optimizing for loss gap parity handles this imbalance more effectively.

Similar to algorithmic fairness in centralized machine learning, determining what makes a federated model fair remains subject to debate and often depends on the specific application (Shi et al., 2023; Benarba and Bouchenak, 2025; Salazar et al., 2026). A widely studied notion of fairness in federated learning is *loss parity* (Li et al., 2020b, 2021; Yue et al., 2023), which aims to equalize local losses between all participating clients. The underlying intuition is that similar loss values indicate the model has learned each client’s data distribution equally well. However, this implicitly assumes that losses are directly comparable across clients—a condition that often fails in heterogeneous settings. In practice, the data distributions of some clients may be intrinsically more challenging to model or suffer from lower quality or resolution, causing their losses to be on inherently different scales. Enforcing equalized losses in such cases can distort optimization and reduce the utility of the global model, sometimes causing a *leveling down* effect—where fairness degrades outcomes for the best-off groups without benefiting the worst-off (Mittelstadt et al., 2023; Zietlow et al., 2022; Maheshwari et al., 2023). We illustrate this with a simple example involving two clients with different data distributions and a linear predictor in Figure 1. Similar problems can arise with *min-max* fairness (Mohri et al., 2019a), which optimizes for the worst-off client but may still compromise overall global performance.

To address these issues, we adopt a fairness objective centered on encouraging *loss gap parity* across participating clients in federated learning. The loss gap of a client is defined as the difference between the loss of the global model and the lowest loss achievable using only the local data of that client. We consider a global model fair when these gaps are similar across clients, ensuring that all clients benefit relatively equally from collaboration. To achieve this, we introduce *EAGLE*, a novel algorithm that augments FedAvg with a regularization term explicitly penalizing the variance of

client loss gaps. By tuning the regularization weight, *EAGLE* allows one to trade off overall accuracy against fairness, consistently reducing disparities in relative improvements compared to optimal local model of each client.

Theoretically, we provide convergence guarantees for *EAGLE* under non-convex local losses, showing that it reaches a saddle point of the regularized objective. We further connect these guarantees to the standard federated learning objective via a novel heterogeneity measure, highlighting how greater client heterogeneity can reduce global utility when enforcing fairness. Empirically, we demonstrate the effectiveness of *EAGLE* on synthetic data as well as the EMNIST and DirtyMNIST benchmarks, with both linear and convolutional models. Our results show that *EAGLE* consistently reduces the variance in loss gaps across clients while maintaining comparable or improved overall performance relative to FedAvg and strong loss parity and min-max fairness baselines.

Related work. Several approaches in the literature define fairness in federated learning through client losses, either by reducing disparities in losses across clients or by optimizing for the worst-case loss (Li et al., 2020b, 2021; Mohri et al., 2019a). The motivation is that a fairer model should perform evenly across clients. However, in heterogeneous settings where clients have different optimal local losses and misaligned optimal models, defining fairness solely based on absolute losses can undesirably penalize clients with easier data, effectively forcing them to perform as poorly as clients with noisier or more complex data. To the best of our knowledge, FOCUS (Chu et al., 2023) is the first work to explicitly question this prevailing notion of fairness and to propose *loss gap parity* as a more suitable objective in heterogeneous settings. Their method builds personalized models for clusters of clients and evaluates fairness by measuring the loss gap of each client relative to its cluster model. However, their theoretical guarantees rely on very strong assumptions on the data distributions, limiting their applicability. In contrast, our approach is more general: it directly regularizes loss gap variance across all clients and provides explicit control over the fairness–utility trade-off via a tunable parameter λ . In a parallel work, Carey and Wu (2025) propose a unified framework for fairness in federated learning, introducing the notion of *desert fairness*, which aims to equalize performance in proportion to the optimal local loss of each client. While their objective is related to ours, their approach again offers limited flexibility in balancing fairness and utility, and lacks formal theoretical guarantees.

2 FAIR FEDERATED LEARNING: FROM LOSS PARITY TO LOSS GAP PARITY

In this paper, we consider a cross-silo federated learning setup with K clients collaborating on a supervised learning task. Let \mathcal{X} denote the feature space and \mathcal{Y} the label space. Each client k has access to a local dataset $D_k = (x_k^i, y_k^i)_{i=1}^{n_k}$ of n_k examples in $\mathcal{X} \times \mathcal{Y}$. We consider models $\theta : \mathcal{X} \rightarrow \mathcal{Y}$ in a hypothesis space \mathcal{H} equipped with a norm $\|\cdot\|$.

The general goal is to learn a global model that performs well across the data of all clients. Let $\ell(\theta, x, y)$ denote a loss function measuring the discrepancy between the prediction of a model $\theta(x)$ and the true label y . The standard federated learning objective is then

$$L(\theta) := \frac{1}{K} \sum_{k=1}^K L_k(\theta),$$

$$\text{with } L_k(\theta) := \frac{1}{n_k} \sum_{i=1}^{n_k} \ell(\theta, x_k^i, y_k^i),$$

which corresponds to minimizing the sum of local empirical losses L_1, \dots, L_K .¹

Optimizing the sum of local losses can lead to significant performance differences across clients when their data distributions are heterogeneous. Data heterogeneity occurs when clients' data differ in their feature distributions, label distributions, or the conditional relationship between features and labels. This variability poses a fundamental challenge in federated learning (Kairouz et al., 2021), calling into question whether collaboration truly benefits individual clients (Cho et al., 2022).

To address the uneven client performance caused by heterogeneity, a common strategy is to enforce some form of *loss parity* (Li et al., 2020b, 2021), aiming for a model that achieves roughly equal local losses across all clients. Here, we consider a definition of approximate loss parity based on the variance of the local losses.

Definition 1 (ε -Loss Parity). *A model $\theta \in \mathcal{H}$ satisfies ε -loss parity if the variance of the client losses $L_k(\theta)$ across the K clients is at most ε , that is:*

$$\mathbb{V}(\{L_k(\theta)\}_{k=1}^K) \leq \varepsilon. \quad (1)$$

where \mathbb{V} denotes the sample variance.

By directly comparing local losses across clients, loss parity implicitly assumes that losses are on the same scale. In heterogeneous settings, however, this assumption often fails, as some clients may have noisier or intrinsically harder-to-predict data. In such

¹While arbitrary weights can be applied to the clients, we consider uniform weights here for simplicity.

cases, achieving loss parity may require to drastically reduce the utility of the global model on best-off clients. In particular, for any model θ that satisfies exact loss parity, i.e., $\mathbb{V}(\{L_k(\theta)\}_{k=1}^K) = 0$, we have: $\forall k \in [K] : L_k(\theta) \geq \max_{k' \in [K]} L_{k'}^*$ where $L_k^* := \min_{\theta \in \mathcal{H}} L_k(\theta)$.

Consequently, clients with lower optimal losses must give up performance to achieve loss parity.

To address this limitation, we adopt in this work a more suitable notion of fairness that focuses on equalizing *loss gaps* relative to the optimal local loss of each client.

Definition 2 (ε -Loss Gap Parity). *A model $\theta \in \mathcal{H}$ satisfies ε -loss gap parity if the variance of client loss gaps $r_k(\theta) := L_k(\theta) - L_k^*$ across the K clients is at most ε , that is:*

$$\mathbb{V}(\{r_k(\theta)\}_{k=1}^K) \leq \varepsilon. \quad (2)$$

Unlike loss parity, loss gap parity promotes fairness in *relative* performance. For instance, under exact loss gap parity (with $\varepsilon = 0$), each client achieves the same excess risk relative to its own optimal local loss. This avoids the leveling-down effect of loss parity: clients with noisier or harder-to-predict data naturally have higher optimal losses, so the global model is not forced to degrade the performance of easier clients to match them. On the other hand, when clients have identical or comparable optimal local losses, loss gap parity effectively reduces to loss parity, since the variance is unchanged by constant additive shifts. Moreover, in homogeneous data settings, the local losses of clients remain similar for any model, so training with objective (2) already yields fairness under both definitions.

In the example of Figure 1, heterogeneity in data distributions creates different levels of task complexity across clients, leading their local optimal models to attain different minimum losses. Enforcing loss parity in this setting compels the global model to keep losses high even for clients with simpler distributions, which can be considered suboptimal in terms of overall performance. By contrast, loss gap parity normalizes losses relative to the local optimum of each client, making them comparable and promoting more balanced—and less trivial—solutions.

3 EAGLE: A FEDERATED LEARNING ALGORITHM FOR LOSS GAP PARITY

In this section, we introduce EAGLE, a new algorithm to enforce loss gap parity in federated learning. Throughout the presentation, we assume that the optimal local losses L_k^* are known, and defer the discussion on how to approximate them in practice to Section 3.2.

To enforce loss gap parity when learning federated models, we propose to add a new regularization term to the standard federated learning objective to penalize models with high variance in loss gaps. Hence, we consider the following optimization problem:

$$\begin{aligned} \arg \min_{\theta \in \mathcal{H}} F(\theta) &:= \frac{1}{K} \sum_{k=1}^K L_k(\theta) + \mathbb{V}(\{r_k(\theta)\}_{k=1}^K) \quad (3) \\ &= \frac{1}{K} \sum_{k=1}^K \underbrace{\left[L_k(\theta) + \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta) - r_{k'}(\theta))^2 \right]}_{:= F_k(\theta)}, \quad (4) \end{aligned}$$

where $r_k(\theta) := L_k(\theta) - L_k^*$ is the gap of client k and the regularization parameter $\lambda > 0$ controls the degree to which loss gap parity should be respected. We note that Problem (3) and Problem (4) are strictly equivalent (Zhang et al., 2012), but choosing the latter makes it easier to solve the problem in a federated way. Indeed, the gradient of F can then be written as

$$\begin{aligned} \nabla F(\theta) &= \frac{1}{K} \sum_{k=1}^K \nabla F_k(\theta) = \\ &= \frac{1}{K} \sum_{k=1}^K \underbrace{\left(1 + \frac{4\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta) - r_{k'}(\theta)) \right)}_{:= w_k(\theta)} \nabla L_k(\theta). \end{aligned}$$

To solve (4), we will adopt an optimization scheme similar to that of *FedAvg* (McMahan et al., 2017), where clients will perform multiple local steps without communicating with the server or the other clients, and then average the obtained local models. A key challenge in optimizing (4) with *FedAvg* is that computing $\nabla F_k(\theta)$ —and, in particular, the weights $w_k(\theta)$ —requires information from all clients. This necessitates inter-client communication after every local step, which contradicts the primary goal of reducing communication. To overcome this challenge, we, instead, choose to fix the weights after each round of communication and only update the local gradient loss after each local step. In other words, we approximate the local gradients by $\nabla \tilde{F}_k(\theta, \theta') = w_k(\theta') \nabla L_k(\theta)$ where θ' refers to the model received from the server at the second to last synchronization step. We summarize this approach, that we call EAGLE, in Algorithm 1.

Choosing the hyperparameter λ . Setting $\lambda = 0$ recovers the standard federated learning objective, while letting $\lambda \rightarrow \infty$ forces the solution of (4) to satisfy loss gap parity exactly for all clients. Empirically, we observe that beyond a certain threshold for λ , efforts to reduce the variance of loss gaps no longer benefit the worst-performing clients in terms of loss gap parity.

Algorithm 1 EAGLE algorithm, in red are the added steps compared to FedAvg.

Require:

- 1: K : number of clients, T : number of communication rounds, I : number of local epochs, η : learning rate, θ^0 : initial model parameters, λ : regularization parameter of EAGLE, $\{L_k^*\}_{k=1}^K$: optimal local losses for each client, $\{D_k\}_{k=1}^K$: local datasets for each client
 - 2: **procedure** SERVEREXECUTE
 - 3: $\forall k \in [K], w_k^0 \leftarrow 1$
 - 4: **for** each round $t = 0, 1, \dots, T - 1$ **do**
 - 5: **for** each client $k \in [K]$ **in parallel do**
 - 6: $\theta_k^{t+1}, r_k^t \leftarrow \text{CLIENTUPDATE}(k, \theta^t, w_k^t)$
 - 7: **end for**
 - 8: Server calculates updated weights $\forall k \in [K], w_k^{t+1} \leftarrow 1 + \frac{4\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k^t - r_{k'}^t)$
 - 9: $\theta^{t+1} \leftarrow \frac{1}{K} \sum_{k \in [K]} \theta_k^{t+1}$
 - 10: **end for**
 - 11: **return** θ_T
 - 12: **end procedure**
 - 13: **procedure** CLIENTUPDATE(k, θ^t, w_k^t)
 - 14: Calculate the loss gap r_k^t on the model θ^t .
 - 15: $\theta_k^{t+1,0} \leftarrow \theta^t$
 - 16: **for** each local epoch $\tau = 0, 1, \dots, I - 1$ **do**
 - 17: Generate an unbiased gradient $\nabla L(\theta_k^{t+1,\tau}; \zeta_k)$
 - 18: $\theta_k^{t+1,\tau+1} \leftarrow \theta_k^{t+1,\tau} - \eta w_k^t \nabla L(\theta_k^{t+1,\tau}; \zeta_k)$
 - 19: **end for**
 - 20: **return** θ_k, r_k
 - 21: **end procedure**
-

Instead, overall performance suffers in order to achieve lower variance, resulting in a “leveling down” effect. The parameter λ thus allows practitioners to control the extent to which loss gap parity is enforced among clients, depending on the specific application.

3.1 Theoretical Analysis

In this section, we analyze the convergence of our approach from two different perspectives. First, we show that EAGLE converges to a stationary point of (4). It is worth noting that obtaining stronger convergence guarantees, for example in terms of closeness to the optimal model, might be challenging in our setting. Indeed, the structure of F contains differences of functions $L_k, L_{k'}$ and thus, even if we assume convexity of the functions $\{L_k\}_{k=1}^K$, F remains non-convex in general. Second, we show that EAGLE returns models that have relatively low gradient norms with respect to the standard FedAvg objective. This result allows to quantify the decrease in utility incurred by our approach

compared to FedAvg when the client losses satisfy the Polyak-Łojasiewicz (PL) condition. We defer all proofs to Appendix A.

To derive our theoretical results, we need several regularity assumptions on the loss of each client, as summarized below.

Assumptions 1. *We assume that the loss functions $\{L_k\}_{k=1}^K$ have the following properties:*

- $\forall k \in [K] : L_k$ is twice differentiable.
- The function L is bounded from below by L^* .
- (Unbiased stochastic gradients) $\mathbb{E}_{\zeta_k}[\nabla L_k(\theta; \zeta_k)] = \nabla L_k(\theta)$.
- (Bounded variance) $\exists \sigma \geq 0 : \mathbb{E}_{\zeta_k}[\|\nabla L_k(\theta; \zeta_k) - \nabla L_k(\theta)\|^2] \leq \sigma^2$.
- (Smoothness) $\forall k \in [K] : L_k$ is β -smooth: $\forall \theta, \theta' \in \mathcal{H} : \|\nabla L_k(\theta) - \nabla L_k(\theta')\| \leq \beta\|\theta - \theta'\|$.
- (Bounded stochastic gradients) $\exists B > 0, \forall \theta \in \mathcal{H}, \forall k \in [K] : \|\nabla L_k(\theta; \zeta_k)\| \leq B$.

These assumptions are fairly common in the literature on the analysis of gradient descent-based algorithms (Wang et al., 2021). They are, for example, satisfied by the cross-entropy loss as long as the feature space \mathcal{X} and hypothesis space \mathcal{H} are bounded.

In our analysis, we propose a novel heterogeneity measure that depends on the loss gaps, namely $\Gamma := \sup_{\theta \in \mathcal{H}} \max_{k, k'} |r_k(\theta) - r_{k'}(\theta)|$. This quantity measures the level of heterogeneity of data across clients based on their optimal losses. Indeed, if the data is perfectly IID and each client has enough data points, then Γ would be small. Otherwise it grows as the functions $\{r_k\}_{k=1}^K$ differ from each other.

Based on the assumptions listed in Assumption 1 and our heterogeneity measure, we can now present the main convergence theorem of the EAGLE algorithm.

Theorem 1 (Convergence to a solution of (4)). *Let $\theta_k^{(t, \tau)}$ refer to the model of client k after t communication rounds and τ local steps and let $\bar{\theta}^{(t, \tau)} := \frac{1}{K} \sum_{k=1}^K \theta_k^{(t, \tau)}$. Let T be the total number of communication rounds and I be the number of local steps between each communication round. Under Assumption 1, for $\eta \leq \frac{1}{(1+4\lambda\Gamma)\beta+8\lambda B^2}$, the sequence of models $\{\bar{\theta}^{(t, \tau)}\}_{t \geq 0, \tau \geq 0}$ generated by Algorithm 1 satisfies:*

$$\begin{aligned} & \frac{1}{TI} \sum_{t=1}^T \sum_{\tau=1}^I \mathbb{E}[\|\nabla F(\bar{\theta}^{(t, \tau)})\|^2] \\ & \leq 2 \frac{1}{\eta TI} (F(\bar{\theta}^{(1, 1)}) - F^*) + \eta^2 I^2 \xi_1 + \eta \frac{\sigma^2}{K} \xi_2, \end{aligned} \quad (5)$$

with $F^* := \arg \min_{\theta \in \mathcal{H}} F(\theta)$, $\xi_1 := 2B^2(1 + 4\lambda\Gamma)^2(\beta^2 + 32\lambda^2(\Gamma^2\beta^2 + B^4))$ and $\xi_2 := ((1 + 4\lambda\Gamma)\beta + 8\lambda B^2)(1 + 4\lambda\Gamma)^2$.

If we further choose $\eta = \frac{1}{\sqrt{TI}}$ and $1 \leq I \leq \sqrt{T}$, the rate can be shown to be sublinear in T , that is:

$$\begin{aligned} & \frac{1}{TI} \sum_{t=1}^T \sum_{\tau=1}^I \mathbb{E}[\|\nabla F(\bar{\theta}^{(t, \tau)})\|^2] \\ & \leq 2 \underbrace{\frac{1}{\sqrt{TI}} (F(\bar{\theta}^{(1, 1)}) - F^*)}_{\mathcal{O}(\frac{1}{\sqrt{T}})} + \frac{I}{T} \xi_1 + \frac{\xi_2}{\sqrt{TI}} \frac{\sigma^2}{K}. \end{aligned} \quad (6)$$

Under standard assumptions on the loss function, we have shown that a carefully chosen step size allows us to recover the standard sublinear convergence rate of algorithms based on SGD in the general non-convex case (Yu et al., 2019). In this result, $I\xi_1$ represents the error related to running EAGLE for multiple local steps before averaging. Naturally, the larger the number of local epochs I and the heterogeneity measure Γ , the larger this error term. Similarly, ξ_2 is an upper bound on the the smoothness parameter of F . In fact, when $\lambda \rightarrow 0$, we have that $\xi_2 \rightarrow \beta$. This recovers the terms introduced in Yu et al. (2019) for FedAvg.

The next theorem establishes convergence guarantees for EAGLE on the standard federated objective $L(\theta) := \frac{1}{K} \sum_{k=1}^K L_k(\theta)$, in the sense of convergence to a neighborhood of stationary points.

Theorem 2 (Convergence to a neighborhood of the standard federated objective). *Let $\theta_k^{(t, \tau)}$ refer to the model of client k after t communication rounds and τ local steps and let $\bar{\theta}^{(t, \tau)} := \frac{1}{K} \sum_{k=1}^K \theta_k^{(t, \tau)}$. Let T be the total number of communication rounds and I be the number of local steps between each communication round. Under Assumption 1, for $\eta \leq \frac{1}{(1+4\lambda\Gamma)\beta+8\lambda B^2}$, the sequence of models $\{\bar{\theta}^{(t, \tau)}\}_{t \geq 0, \tau \geq 0}$ generated by Algorithm 1 satisfies:*

$$\begin{aligned} & \frac{1}{TI} \sum_{t=1}^T \sum_{\tau=1}^I \mathbb{E}[\|\nabla L(\bar{\theta}^{(t, \tau)})\|^2] \leq 2 \frac{1}{\eta TI} (L(\bar{\theta}^{(1, 1)}) - L^*) \\ & \quad + \underbrace{\frac{32\lambda^2\Gamma^2 B^2}{\text{neighborhood of the solution relative to the heterogeneity}}}_{\text{neighborhood of the solution relative to the heterogeneity}} + \eta \frac{\sigma^2}{K} \xi_2 \\ & \quad + 8\beta^2 \eta^2 I^2 (1 + 4\lambda\Gamma)^2 B^2, \end{aligned} \quad (7)$$

with $\xi_2 := ((1 + 4\lambda\Gamma)\beta + 8\lambda B^2)(1 + 4\lambda\Gamma)^2$.

If we further assume that $L(\theta)$ is μ -Polyak-Łojasiewicz (PL), that is $\forall \theta \in \mathcal{H} : \frac{1}{2} \|\nabla L(\theta)\| \geq \mu(L(\theta) - L^*)$, then

we have that:

$$\begin{aligned} \frac{1}{T\Gamma} \sum_{t=1}^T \sum_{\tau=1}^I \mathbb{E}[L(\bar{\theta}^{(t,\tau)}) - L^*] &\leq 4 \frac{\mu}{\eta T \Gamma} (L(\bar{\theta}^{(1,1)}) - L^*) \\ &+ 2\eta \frac{\sigma^2}{K} \xi_2 + 16\beta^2 \eta^2 I^2 (1 + 4\lambda\Gamma)^2 B^2 + \underbrace{62\mu\lambda^2 \Gamma^2 B^2}_{\text{Loss in utility}}. \end{aligned} \quad (8)$$

Theorem 2 bounds the potential loss in utility induced by the fairness regularization, as the only term that does not vanish with an appropriate choice of η is of order $\mathcal{O}(\lambda^2 \Gamma^2)$. As expected, lower heterogeneity Γ or smaller values of λ lead to a reduced loss in utility.

3.2 Practical Considerations

In this section, we tackle two issues that may arise when using EAGLE in practice, namely the fact that optimal local losses are not available and that the added regularization term may create some instability in the optimization process.

Optimal local losses. So far, we assumed that the optimal losses L_k^* were available. However, this is an unrealistic assumption in practice since even getting a reliable approximation of this quantity would require each client to have access to sufficiently many examples to learn a good model on their own data distribution. In the experiments of Section 4, we tackle this issue by splitting the data of each client into a training and a validation set. We then learn the best possible model on the train set of each client and approximate L_k^* on their validation set. We provide additional details on how to obtain the best possible approximation of L_k^* in Appendix B.1.

Instability of EAGLE. Our approach can be seen as a reweighting approach where each client gets a new weight w_k^t at each communication round. These weights are adaptive and are based on the level of loss gap parity of the global model. This can be equivalently viewed as performing SGD locally with varying learning rates. Many model architectures are sensitive to this hyperparameter, and incorrect choices can lead to exploding gradients, even in simple models (Meng et al., 2024). To avoid this issue, we normalize the weights $\{w_k^t\}_{k=1}^K$ so that they have an L_2 norm of 1. This preserves the sign of the weights and their relative importance, while keeping their magnitude constant, preventing unintended variations in the effective learning rate.

4 EXPERIMENTS

In this section, we empirically evaluate EAGLE against *FedAvg* and two algorithms that aim for loss parity. This effectively allows us to highlight the issues of fairness unaware training (*FedAvg*) and that of the training that aims for a fairness definition (loss parity) that may not adequately handle data heterogeneity.

The section is structured as follows. In the first part, we showcase experiments on logistic regression. We begin with a synthetic dataset where having clearly separable data in the input space is actually a disadvantage for clients under a loss-parity-enforcing algorithm. We then demonstrate how EAGLE overcomes this issue by assigning higher weights to clients with linearly separable data. Next, we show that such heterogeneity in optimal local losses also arises in a real dataset (EMNIST (Cohen et al., 2017)). In the second part, we present experiments with a CNN model to highlight the limitations of loss-parity-enforcing approaches and unconstrained training on more complex models. These experiments are conducted on both the EMNIST and DirtyMNIST datasets (Mukhoti et al., 2023).

Baselines. Throughout this section, we evaluate EAGLE on accuracy and loss gap fairness metrics. We compare it with: (i) *FedAvg* for unconstrained training; (ii) *q-FedAvg* (*q-FFL*) (Li et al., 2020b), which aims to balance client losses by raising each local loss to the power $q + 1$, with q a tunable parameter, thereby giving higher weights to the clients with larger losses; (iii) *Agnostic Federated Learning* (*AFL*) (Mohri et al., 2019b), which adopts an *egalitarian* strategy aimed at minimizing the loss of the worst-performing client.

Metrics. We evaluate the algorithms in terms of fairness, measured by the variance of loss gaps, and utility, quantified as the balanced accuracy across clients. We also report the performance of the best and worst clients (based on loss gaps) to determine whether fairness is achieved by improving the utility of the worst-performing clients or by simply leveling down the better-performing ones.

In all experiments, the loss gaps $r_k(\theta)_{k=1}^K$ are computed on a held-out validation set to prevent overfitting to the training data. Note that loss gaps can be negative, indicating that federated learning improves client generalization. In other words, the federated model can outperform local training on the validation set. When all loss gaps are negative, achieving loss gap parity ensures that every client benefits equally from federated learning, receiving the same improvement in generalization on their respective validation sets.

Datasets. We experiment on the following datasets.

Figure 2: EMNIST data: $\min\{L_k^*\}_{k \in [10]}$ (red) and $\max\{L_k^*\}_{k \in [10]}$ (blue) for a heterogeneous data split ($\alpha = 0.1$) and a homogeneous split ($\alpha = 2000$) using a linear model. As expected, the range of optimal local losses is larger for non-iid data.

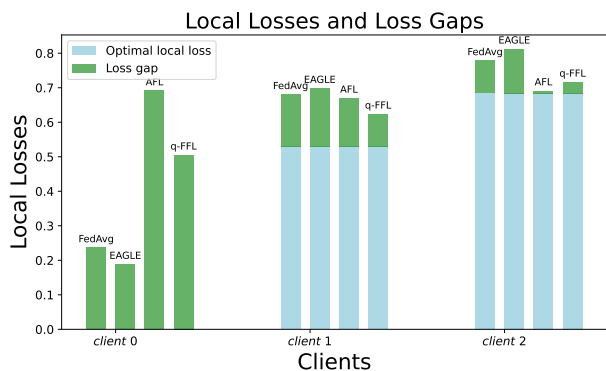

Figure 3: Local losses and local gaps for EAGLE($\lambda = 2.0$), q-FFL ($q = 5.0$) and AFL. The optimal local loss of client 0 is nearly 0 by design and thus only its loss gap is visible in the plot. By balancing the losses across clients, q-FFL and AFL prioritize learning a good classifier for clients 1 and 2, which harms the performance of client 0. In contrast, by balancing the loss *gaps* across clients, EAGLE allows all clients to benefit equally from federated learning.

- **Synthetic data.** We consider three clients collaborating to fit a linear separator of 2-dimensional data into two classes $Y = \{-1, 1\}$, each client samples 100 data points from the following underlying distributions:

- client 0: $X|Y = 1 \sim \mathcal{N}([2, 2], \mathbb{I}_2)$ and $X|Y = -1 \sim \mathcal{N}([-2, -2], \mathbb{I}_2)$,
- client 1: $X|Y = 1 \sim \mathcal{N}([0.5, 0.5], \mathbb{I}_2)$ and $X|Y = -1 \sim \mathcal{N}([-0.5, -0.5], \mathbb{I}_2)$,
- client 2: $X|Y = 1 \sim \mathcal{N}([0.1, 0.1], \mathbb{I}_2)$ and $X|Y = -1 \sim \mathcal{N}([-0.1, -0.1], \mathbb{I}_2)$,

where \mathbb{I}_2 is the 2×2 identity matrix. We also rotate the data of client 2 around $x_0 = \{0, 0\}$ by 45 degrees to avoid the case where all clients share an optimal separator. The resulting distributions

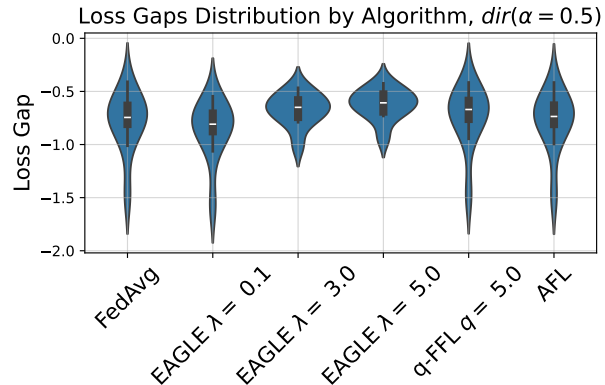

Figure 4: The distribution of loss gaps for the 10 clients for a heterogeneous split ($\alpha = 0.5$) with CNN model. We notice that in the case of high non-iid data, EAGLE reduces the gap of the worst performing client in terms of loss and achieves less variance than other baselines.

are depicted in the Appendix (Figure 5).

- **EMNIST.** To simulate federated learning with varying degrees of data heterogeneity, we split the EMNIST dataset (Cohen et al., 2017) among 10 clients using a Dirichlet-based allocation method (Hsu et al., 2019). The heterogeneity of the split is parameterized by α (the smaller, the more heterogeneous). Details of the splitting procedure are provided in Appendix B.2. This heterogeneous allocation induces differences in the optimal local metrics across clients, as illustrated in Figure 2.
- **DirtyMNIST.** The DirtyMNIST dataset labels examples as either clean or ambiguous, depending on how confidently humans can assign a label. We exploit this attribute to distribute 8,000 examples across 5 clients, each receiving a different proportion of ambiguous images—from 0% in client 0 up to 100% in client 5. The intuition is that a higher fraction of ambiguous examples leads to a higher optimal local loss for that client.

4.1 Results

Here, we illustrate the performance of the different algorithms on logistic regression with a linear model and on image classification using a CNN.

Synthetic data. Our synthetic construction allows us to simulate variable levels of data separability between clients. As shown in Figure 3, methods that directly balance client losses assign higher weights to clients 1 and 2, steering the optimization toward their optimal models while increasing the loss for client 0. By focusing on balancing loss gaps instead of raw losses,

Table 1: Performance of different algorithms on EMNIST with a highly heterogeneous split ($\alpha = 0.1$) and a linear model. EAGLE achieves the best performance for the worst-performing client in terms of loss gaps, while maintaining accuracy comparable to the other baselines.

Algorithm	$\alpha = 0.1$			
	$\max_{k \in [K]} r_k(\theta) \downarrow$	$\min_{k \in [K]} r_k(\theta) \downarrow$	accuracy \uparrow	$\mathbb{V}_{k \in [K]} r_k(\theta) \downarrow$
AFL	0.152 (± 0.207)	-0.477 (± 0.155)	0.687 (± 0.003)	0.037 (± 0.026)

EAGLE $\lambda = 5.0$	0.434 ± 0.104	0.249 ± 0.096	0.814 ± 0.004	0.006 ± 0.002

EAGLE avoids this bias, ensuring that clients with lower optimal training losses are not disadvantaged by the optimization. The evolution of training losses for *q-FFL*, *AFL*, and *EAGLE* is shown in Figure 6 of the Appendix.

EMNIST. Table 1 reports detailed utility and fairness metrics for different baselines using a linear model on a highly heterogeneous data split ($\alpha = 0.1$). EAGLE maintains accuracy comparable to other baselines. Increasing λ gives more weight to the regularization term in the objective, producing models with smaller disparities in loss gaps but at the cost of lower utility. Beyond a certain λ , EAGLE begins leveling down performance across all clients to further reduce the variance in loss gaps, which is expected. Results for less heterogeneous splits are provided in Section B.6 of the Appendix.

We observe similar trends with a CNN model; detailed results are also in Section B.6. Figure 4 illustrates the distribution of loss gaps across clients on a heterogeneous split ($\alpha = 0.5$). EAGLE is the only algorithm that effectively reduces the variance of loss gaps, benefiting the worst-performing clients.

DirtyMNIST. These experiments illustrate the scenario where clients have different optimal local losses but share the same optimal model. In this setting, the gradients from all clients point in similar directions, so methods that reweight gradients to enforce fairness behave similarly, as a model optimized for one client is also effective for the others. Detailed results are provided in Table 2. Consistent with previous observations, EAGLE improves loss-gap parity and achieves the best performance for the worst-performing client.

5 DISCUSSION AND CONCLUSION

In this work, we addressed the problem of client fairness in federated learning with heterogeneous data. We argued that standard loss parity can lead to severe leveling-down effects and that the notion of loss-gap parity is a more suitable alternative. To enforce this fairness criterion, we introduced EAGLE, a regularized federated objective that explicitly controls the trade-off between utility and loss-gap parity.

Theoretically, we proved that EAGLE converges for non-convex losses and established a connection to the standard federated learning objective through a novel heterogeneity measure. Empirically, we evaluated the approach on both synthetic and real datasets, demonstrating that it achieves the intended fairness improvements when the trade-off hyperparameter is chosen appropriately.

Some limitations of our method include the assumptions that the $\{L_k^*\}_{k=1}^K$ can be reliably estimated and that all clients remain continuously available for communication during training. These requirements limit its applicability in cross-device scenarios with constrained computation and bandwidth. Furthermore, as most fairness-promoting approaches, the method’s effectiveness depends critically on careful tuning of the hyperparameter λ , as inappropriate choices can lead to a leveling-down effect across clients.

Checklist

1. For all models and algorithms presented, check if you include:
 - (a) A clear description of the mathematical setting, assumptions, algorithm, and/or model. [Yes]
 - (b) An analysis of the properties and complexity (time, space, sample size) of any algorithm. [Yes]
 - (c) (Optional) Anonymized source code, with specification of all dependencies, including external libraries. [Yes] (Submitted after acceptance)
2. For any theoretical claim, check if you include:
 - (a) Statements of the full set of assumptions of all theoretical results. [Yes]
 - (b) Complete proofs of all theoretical results. [Yes]
 - (c) Clear explanations of any assumptions. [Yes]
3. For all figures and tables that present empirical results, check if you include:
 - (a) The code, data, and instructions needed to reproduce the main experimental results (either in the supplemental material or as a URL). [Yes]
 - (b) All the training details (e.g., data splits, hyperparameters, how they were chosen). [Yes]
 - (c) A clear definition of the specific measure or statistics and error bars (e.g., with respect to the random seed after running experiments multiple times). [Yes]
 - (d) A description of the computing infrastructure used. (e.g., type of GPUs, internal cluster, or cloud provider). [Yes]
4. If you are using existing assets (e.g., code, data, models) or curating/releasing new assets, check if you include:
 - (a) Citations of the creator If your work uses existing assets. [Yes]

- (b) The license information of the assets, if applicable. [Not Applicable]
 - (c) New assets either in the supplemental material or as a URL, if applicable. [Not Applicable]
 - (d) Information about consent from data providers/curators. [Not Applicable]
 - (e) Discussion of sensible content if applicable, e.g., personally identifiable information or offensive content. [Not Applicable]
5. If you used crowdsourcing or conducted research with human subjects, check if you include:
- (a) The full text of instructions given to participants and screenshots. [Not Applicable]
 - (b) Descriptions of potential participant risks, with links to Institutional Review Board (IRB) approvals if applicable. [Not Applicable]
 - (c) The estimated hourly wage paid to participants and the total amount spent on participant compensation. [Not Applicable]

Supplementary Material

A DETAILED THEORETICAL RESULTS AND PROOFS

In this appendix, we provide the convergence proof for EAGLE. To facilitate understanding of the proof, all notations are defined in Table 3.

Recall that EAGLE optimizes the following objective:

$$\arg \min_{\theta \in \mathcal{H}} F(\theta) := \frac{1}{K} \sum_{k=1}^K \left[L_k(\theta) + \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta) - r_{k'}(\theta))^2 \right], \quad (9)$$

where $r_k(\theta) := L_k(\theta) - L_k^*$, and $\lambda > 0$ is a regularization parameter to be tuned in practice.

Our proof adapts the analysis of FedAvg in Yu et al. (2019), where we establish an upper bound on the smoothness parameter and a bound on the gradient norm for our new regularized objective, following a similar proof strategy.

We first observe that the gradient of F is equal to :

$$\nabla F(\theta) := \frac{1}{K} \sum_{k=1}^K \underbrace{\left(1 + \frac{4\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta) - r_{k'}(\theta)) \right)}_{w_k(\theta)} \nabla L_k(\theta)$$

We introduce a new ‘‘proxy’’ gradient

$$\nabla \tilde{F}_k(\theta, \theta') := \underbrace{\left(1 + \frac{4\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta') - r_{k'}(\theta')) \right)}_{w_k(\theta')} \nabla L_k(\theta)$$

Here, the functions r_k and $r_{k'}$ are evaluated on a different model than the stochastic gradient ∇L_k , this will remove the need for communication between synchronization rounds.

We will use two time counters, t to denote the the number of synchronizations and τ to index the local step, and we will use k in subscript to index the client. For example, $\theta_k^{(t,\tau)}$ denotes the model of client k after t synchronizations and τ local steps. Additionally, we denote a virtual average model $\bar{\theta}^{(t,\tau)} := \frac{1}{K} \sum_{k=1}^K \theta_k^{(t,\tau)}$ to represent the average of local models within clients between two rounds communication. For all the results mentioned in this section, the expectation \mathbb{E} with respect to some function of the model $\bar{\theta}^{(t,\tau)}$ is taken with respect to the minibatching noises $\zeta_1, \zeta_2, \dots, \zeta_k$ at all times up to (t, τ) .

With this notation, we have: $\theta_k^{(t+1,0)} := \frac{1}{K} \sum_{k=1}^K \theta_k^{(t,I)} = \bar{\theta}^{(t,I)}$. In words, at the start of each local training phase, the local models are initialized with the average of the models of all clients.

We can derive a recursive update on the virtual model:

$$\bar{\theta}^{(t,\tau+1)} = \frac{1}{K} \sum_{k=1}^K \theta_k^{(t,\tau+1)} \quad (10)$$

$$= \frac{1}{K} \sum_{k=1}^K \theta_k^{(t,\tau)} - \eta \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}; \zeta_k) \quad (11)$$

$$= \bar{\theta}^{(t,\tau)} - \eta \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}; \zeta_k). \quad (12)$$

Notation	Description
λ	Regularization parameter to be controlled by the user
θ	An arbitrary model in the space
t	counter of synchronization rounds
τ	counter of local steps
$\theta_k^{(t,\tau)}$	Local model inside each client k , after t syncs and τ local steps.
$\bar{\theta}^{(t,\tau)}$	$\frac{1}{K} \sum_{k=1}^K \theta_k^{(t,\tau)}$
K	Number of clients
$L_k(\theta)$	Loss of client k
$F_k(\theta)$	$L_k(\theta) + \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta) - r_{k'}(\theta))^2$
$\nabla L_k(\theta)$	Gradient of L_k
$\nabla L_k(\theta, \zeta_k)$	(Minibatch) Stochastic Gradient of L_k
σ	Bound on the variance of stochastic gradients of L_k
β	Smoothness parameter of L_k
Γ	Heterogeneity measure, $\Gamma := \sup_{\theta \in \mathcal{H}} \max_{k,k'} r_k(\theta) - r_{k'}(\theta) $
B	Bound on $\ \nabla L_k(\theta; \zeta_k)\ ^2$
$w_k(\theta)$	$(1 + 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta) - r_{k'}(\theta)))$
$\nabla \tilde{F}_k(\theta)$	$w_k(\theta) \nabla L_k(\theta)$
$\nabla \tilde{F}_k(\theta, \theta')$	$w_k(\theta') \nabla L_k(\theta)$

Table 3: Table of notations and their descriptions

We will first introduce lemmas that are useful in our proof of our main results. Then, we will restate the results of the main paper and provide their proofs.

As a preliminary step, we establish bounds on the weights $w_k(\theta), w_k(\theta')$, which will be useful in the subsequent analysis.

Lemma 1 (Properties of the weights of clients $w_k(\theta)$). *For any two models $\theta, \theta' \in \mathcal{H}$, the weights $w_k(\theta), w_k(\theta')$ satisfy the following:*

$$|w_k(\theta)| \leq 1 + 4\lambda\Gamma, \quad (13)$$

$$|w_k(\theta) - w_k(\theta')| \leq 8\lambda B \|\theta - \theta'\|. \quad (14)$$

Proof. Indeed, for a $\theta \in \mathcal{H}$ we have for the first property:

$$|w_k(\theta)| = \left| 1 + 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta) - r_{k'}(\theta)) \right|, \quad (15)$$

$$\stackrel{\text{Triangle inequality}}{\leq} 1 + 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} |r_k(\theta) - r_{k'}(\theta)|, \quad (16)$$

$$\stackrel{|r_k(\theta) - r_{k'}(\theta)| \leq \Gamma}{\leq} 1 + 4\lambda\Gamma. \quad (17)$$

And for a $\theta, \theta' \in \mathcal{H}$ we have for the second property:

$$|w_k(\theta) - w_k(\theta')| \leq \left| 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta) - r_{k'}(\theta)) - 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta') - r_{k'}(\theta')) \right|, \quad (18)$$

$$\stackrel{\text{Triangular inequality}}{\leq} 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} |r_k(\theta) - r_k(\theta') + r_{k'}(\theta') - r_{k'}(\theta)|, \quad (19)$$

$$\stackrel{L_k \text{ is } B\text{-Lipschitz}}{\leq} 8\lambda B \|\theta - \theta'\|. \quad \square$$

The following lemma derives an upper bound on the norm of $\|\nabla \tilde{F}_k(\theta, \theta'; \zeta_k)\|$:

Lemma 2 (Bounded norm of the gradient of \tilde{F}_k). *Under the assumption that the norm of the stochastic gradient of L_k is bounded by a constant B , for any two models $\theta, \theta' \in \mathcal{H}$, we have:*

$$\|\nabla \tilde{F}_k(\theta, \theta'; \zeta_k)\| \leq (1 + 4\lambda\Gamma)B. \quad (20)$$

Proof. We have $\forall \theta, \theta' \in \mathcal{H}$:

$$\|\nabla F_k(\theta, \theta'; \zeta_k)\| = \left\| w_k(\theta') \nabla L_k(\theta; \zeta_k) \right\| \quad (21)$$

$$= |w_k(\theta')| \cdot \|\nabla L_k(\theta; \zeta_k)\| \quad (22)$$

$$\stackrel{\text{Lemma 1, } \|\nabla L_k(\theta; \zeta_k)\| \leq B}{\leq} (1 + 4\lambda\Gamma)B. \quad \square$$

The second lemma derives an upper bound on the smoothness parameter of the regularized local objective $F_k(\theta) := L_k(\theta) + \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\theta) - r_{k'}(\theta))^2$:

Lemma 3. *Under the assumptions 1, $\forall k \in [K]$: F_k is smooth with a smoothness parameter equal to: $(1 + 4\lambda\Gamma)\beta + 8\lambda B^2$.*

$$\forall \theta \in \mathcal{H} : \|\nabla^2 F_k(\theta)\| \leq (1 + 4\lambda\Gamma)\beta + 8\lambda B^2. \quad (23)$$

Proof. We know that if F_k is twice differentiable, we have:

$$F_k \text{ is } \beta' \text{-smooth} \iff \forall \theta \in \mathcal{H} : \|\nabla^2 F_k(\theta)\| \leq \beta', \quad (24)$$

Let's derive an upper bound on β' . We have:

$$\begin{aligned} \nabla^2 F_k(\theta) &= \frac{\partial}{\partial \theta} \left[w_k(\theta) \nabla L_k(\theta) \right] \\ &= w_k(\theta) \nabla^2 L_k(\theta) + 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (\nabla L_k(\theta) - \nabla L_{k'}(\theta)) \nabla L_k(\theta)^T \end{aligned}$$

Thus:

$$\|\nabla^2 F_k(\theta)\| = \left\| w_k(\theta) \nabla^2 L_k(\theta) + 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (\nabla L_k(\theta) - \nabla L_{k'}(\theta)) \nabla L_k(\theta)^T \right\|, \quad (25)$$

$$\begin{aligned} \|\nabla^2 F_k(\theta)\| &\leq |w_k(\theta)| \underbrace{\|\nabla^2 L_k(\theta)\|}_{\leq \beta, \text{ since } L_k \text{ is } \beta \text{-smooth}} \\ &\quad + \left\| 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (\nabla L_k(\theta) - \nabla L_{k'}(\theta)) \nabla L_k(\theta)^T \right\|, \end{aligned} \quad (26)$$

$$\stackrel{\text{Lemma 1}}{\leq} (1 + 4\lambda\Gamma)\beta + \left\| 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (\nabla L_k(\theta) - \nabla L_{k'}(\theta)) \nabla L_k(\theta)^T \right\|, \quad (27)$$

$$\begin{aligned} &\leq (1 + 4\lambda\Gamma)\beta \\ &\quad + 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (\|\nabla L_k(\theta) \nabla L_{k'}(\theta)^T\| + \|\nabla L_{k'}(\theta) \nabla L_k(\theta)^T\|), \end{aligned} \quad (28)$$

$$\begin{aligned} &\stackrel{\|AB\| \leq \|A\| \|B\|}{\leq} (1 + 4\lambda\Gamma)\beta \\ &\quad + 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (\|\nabla L_k(\theta)\| \|\nabla L_k(\theta)^T\| + \|\nabla L_{k'}(\theta)\| \|\nabla L_k(\theta)^T\|), \end{aligned} \quad (29)$$

$$\stackrel{\|\nabla L_k(\theta; \zeta_k)\| \leq B}{\leq} \underbrace{\left((1 + 4\lambda\Gamma)\beta + 8\lambda B^2 \right)}_{\beta'}. \quad (30)$$

□

The next lemma bounds the difference between the local models and the averaged model.

Lemma 4 (Bounded distance of local and average models). *After t synchronization steps, and τ local steps, under assumptions 1, the algorithm 1 satisfies:*

$$\mathbb{E}[\|\bar{\theta}^{(t,\tau)} - \theta_k^{t,\tau}\|^2] \leq 4\eta^2 I^2 (1 + 4\lambda\Gamma)^2 B^2. \quad (31)$$

Proof. We have:

$$\bar{\theta}^{(t,\tau)} = \frac{1}{K} \sum_{k=1}^K \theta_k^{(t,\tau)} \quad (32)$$

$$= \frac{1}{K} \sum_{k=1}^K \theta_k^{(t,\tau-1)} - \eta \nabla \tilde{F}_k(\theta_k^{(t,\tau-1)}, \bar{\theta}^{(t,0)}; \zeta_k) \quad (33)$$

$$= \bar{\theta}^{(t,\tau-1)} - \eta \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau-1)}, \bar{\theta}^{(t,0)}; \zeta_k) \quad (34)$$

$$= \bar{\theta}^{(t,0)} - \eta \frac{1}{K} \sum_{k=1}^K \sum_{\tau'=0}^{\tau-1} \nabla \tilde{F}_k(\theta_k^{(t,\tau')}, \bar{\theta}^{(t,0)}; \zeta_k) \quad (35)$$

And similarly:

$$\theta_k^{(t,\tau)} = \theta_k^{(t,\tau-1)} - \eta \nabla \tilde{F}_k(\theta_k^{(t,\tau-1)}, \bar{\theta}_k^{(t,0)}; \zeta_k) \quad (36)$$

$$= \bar{\theta}^{(t,0)} - \eta \sum_{\tau'=0}^{\tau-1} \nabla \tilde{F}_k(\theta_k^{(t,\tau')}, \bar{\theta}^{(t,0)}; \zeta_k) \quad (37)$$

Therefore:

$$\begin{aligned} & \mathbb{E}[\|\bar{\theta}^{(t,\tau)} - \theta_k^{(t,\tau)}\|^2] \\ &= \eta^2 \mathbb{E} \left[\left\| \sum_{\tau'=0}^{\tau-1} \frac{1}{K} \left(\sum_{k'=1}^K \nabla \tilde{F}_{k'}(\theta_{k'}^{(t,\tau')}, \bar{\theta}^{(t,0)}; \zeta_{k'}) \right) - \sum_{\tau'=0}^{\tau-1} \nabla \tilde{F}_k(\theta_k^{(t,\tau')}, \bar{\theta}^{(t,0)}; \zeta_k) \right\|^2 \right] \end{aligned} \quad (38)$$

$$\leq 2\eta^2 \tau \left(\sum_{\tau'=0}^{\tau-1} \mathbb{E} \left[\left\| \frac{1}{K} \left(\sum_{k'=1}^K \nabla \tilde{F}_{k'}(\theta_{k'}^{(t,\tau')}, \bar{\theta}^{(t,0)}; \zeta_{k'}) \right) \right\|^2 \right] + \mathbb{E} \left[\left\| \nabla \tilde{F}_k(\theta_k^{(t,\tau')}, \bar{\theta}^{(t,0)}; \zeta_k) \right\|^2 \right] \right) \quad (39)$$

$$\stackrel{\text{Lemma 2}}{\leq} 2 \cdot 4\eta^2 \tau^2 (1 + 4\lambda\Gamma)^2 B^2 \quad (40)$$

$$\stackrel{\tau \leq I}{\leq} 4\eta^2 I^2 (1 + 4\lambda\Gamma)^2 B^2. \quad \square$$

Theorem 1 (Convergence to a solution of (4)). *Let $\theta_k^{(t,\tau)}$ refer to the model of client k after t communication rounds and τ local steps and let $\bar{\theta}^{(t,\tau)} := \frac{1}{K} \sum_{k=1}^K \theta_k^{(t,\tau)}$. Let T be the total number of communication rounds and I be the number of local steps between each communication round. Under Assumption 1, for $\eta \leq \frac{1}{(1+4\lambda\Gamma)\beta+8\lambda B^2}$, the sequence of models $\{\bar{\theta}^{(t,\tau)}\}_{t \geq 0, \tau \geq 0}$ generated by Algorithm 1 satisfies:*

$$\frac{1}{TI} \sum_{t=1}^T \sum_{\tau=1}^I \mathbb{E}[\|\nabla F(\bar{\theta}^{(t,\tau)})\|^2] \leq 2 \frac{1}{\eta TI} (F(\bar{\theta}^{(1,1)}) - F^*) + \eta^2 I^2 \xi_1 + \eta \frac{\sigma^2}{K} \xi_2,$$

with $F^* := \arg \min_{\theta \in \mathcal{H}} F(\theta)$, $\xi_1 := 2B^2(1 + 4\lambda\Gamma)^2(\beta^2 + 32\lambda^2(\Gamma^2\beta^2 + B^4))$ and $\xi_2 := ((1 + 4\lambda\Gamma)\beta + 8\lambda B^2)(1 + 4\lambda\Gamma)^2$.

If we further choose $\eta = \frac{1}{\sqrt{TI}}$ and $1 \leq I \leq \sqrt{T}$, the rate can be shown to be sublinear in T , that is:

$$\frac{1}{TI} \sum_{t=1}^T \sum_{\tau=1}^I \mathbb{E}[\|\nabla F(\bar{\theta}^{(t,\tau)})\|^2] \leq \underbrace{2 \frac{1}{\sqrt{IT}} (F(\bar{\theta}^1) - F^*) + \frac{I}{T} \xi_1 + \frac{\xi_2}{\sqrt{IT}} \frac{\sigma^2}{K}}_{\mathcal{O}(\frac{1}{\sqrt{T}})}.$$

Proof. First, let us start by upper bounding the following quantity (the difference of the applied gradient to the actual gradient of ∇F_k):

$$\|\nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) - \nabla F_k(\bar{\theta}^{(t,\tau)})\|^2 = \left\| w_k(\bar{\theta}^{(t,0)}) \nabla L_k(\theta_k^{(t,\tau)}) - w_k(\bar{\theta}^{(t,\tau)}) \nabla L_k(\bar{\theta}^{(t,\tau)}) \right\|^2 \quad (41)$$

$$= \|w_k(\bar{\theta}^{(t,0)}) (\nabla L_k(\theta_k^{(t,\tau)}) - \nabla L_k(\bar{\theta}^{(t,\tau)})) + (w_k(\bar{\theta}^{(t,0)}) - w_k(\bar{\theta}^{(t,\tau)})) \nabla L_k(\bar{\theta}^{(t,\tau)})\|^2 \quad (42)$$

$$\leq \left[(1 + 4\lambda\Gamma) \|\nabla L_k(\theta_k^{(t,\tau)}) - \nabla L_k(\bar{\theta}^{(t,\tau)})\| + |w_k(\bar{\theta}^{(t,0)}) - w_k(\bar{\theta}^{(t,\tau)})| B \right]^2 \quad (43)$$

$$\stackrel{L_k \text{ is } B\text{-smooth, Lemma 1}}{\leq} \left[(1 + 4\lambda\Gamma) \beta \|\theta_k^{(t,\tau)} - \bar{\theta}^{(t,\tau)}\| + 8\lambda B^2 \|\bar{\theta}^{(t,0)} - \bar{\theta}^{(t,\tau)}\| \right]^2 \quad (44)$$

$$\stackrel{(a+b)^2 \leq 2a^2 + 2b^2}{\leq} 2 \left[(1 + 4\lambda\Gamma)^2 \beta^2 \|\theta_k^{(t,\tau)} - \bar{\theta}^{(t,\tau)}\|^2 + 64\lambda^2 B^4 \|\bar{\theta}^{(t,0)} - \bar{\theta}^{(t,\tau)}\|^2 \right] \quad (45)$$

$$\stackrel{\text{Lemma 4 and 2}}{\leq} 2 \left[(1 + 4\lambda\Gamma)^2 \beta^2 4\eta^2 I^2 (1 + 4\lambda\Gamma)^2 B^2 + 64\lambda^2 B^4 2\eta^2 I^2 (1 + 4\lambda)^2 B^2 \right] \quad (46)$$

$$= 8\eta^2 I^2 (1 + 4\lambda)^2 B^2 \left[(1 + 4\lambda\Gamma)^2 \beta^2 + 32\lambda^2 B^4 \right]. \quad (47)$$

Therefore we have:

$$\begin{aligned} & \left\| \frac{1}{K} \sum_{k=1}^K \left[\nabla \tilde{F}_k(\bar{\theta}^{(t,\tau)}, \bar{\theta}^{(t,\tau)}) - \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right] \right\|^2 \\ & \leq \frac{1}{K} \sum_{k=1}^K \|\nabla \tilde{F}_k(\bar{\theta}^{(t,\tau)}, \bar{\theta}^{(t,\tau)}) - \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)})\|^2. \end{aligned} \quad (48)$$

$$\leq 8\eta^2 I^2 (1 + 4\lambda)^2 B^2 \left[(1 + 4\lambda\Gamma)^2 \beta^2 + 32\lambda^2 B^4 \right]. \quad (49)$$

Since each F_k is smooth with smoothness equal to $(1 + 4\lambda\Gamma)\beta + 8\lambda B^2$, $F(\theta) := \frac{1}{K} \sum_{k=1}^K F_k(\theta)$ is also $(1 + 4\lambda\Gamma)\beta + 8\lambda B^2$ -smooth. Therefore:

$$\begin{aligned} & \mathbb{E}[F(\bar{\theta}^{(t,\tau+1)})] \\ & \leq \mathbb{E}[F(\bar{\theta}^{(t,\tau)})] + \mathbb{E}[\langle \nabla F(\bar{\theta}^{(t,\tau)}), \bar{\theta}^{(t,\tau+1)} - \bar{\theta}^{(t,\tau)} \rangle] + \frac{(1 + 4\lambda\Gamma)\beta + 8\lambda B^2}{2} \mathbb{E}[\|\bar{\theta}^{(t,\tau+1)} - \bar{\theta}^{(t,\tau)}\|^2] \end{aligned} \quad (50)$$

$$\begin{aligned} & = \mathbb{E}[F(\bar{\theta}^{(t,\tau)})] - \eta \mathbb{E} \left[\left\langle \nabla F(\bar{\theta}^{(t,\tau)}), \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}; \zeta_k) \right\rangle \right] \\ & \quad + \frac{(1 + 4\lambda\Gamma)\beta + 8\lambda B^2}{2} \eta^2 \mathbb{E} \left[\left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}; \zeta_k) \right\|^2 \right] \end{aligned} \quad (51)$$

$$\begin{aligned} & \stackrel{\mathbb{E}_{\zeta_k}[\nabla \tilde{F}_k(\theta, \theta'; \zeta_k)] = \nabla \tilde{F}_k(\theta, \theta')}{=} \mathbb{E}[F(\bar{\theta}^{(t,\tau)})] - \eta \mathbb{E} \left[\left\langle \nabla F(\bar{\theta}^{(t,\tau)}), \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\rangle \right] \\ & \quad + \frac{(1 + 4\lambda\Gamma)\beta + 8\lambda B^2}{2} \eta^2 \mathbb{E} \left[\left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}; \zeta_k) \right\|^2 \right] \end{aligned} \quad (52)$$

We have:

$$\eta^2 \mathbb{E} \left[\left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}; \zeta_k) \right\|^2 \right] \quad (53)$$

$$\stackrel{(a)}{=} \eta^2 \mathbb{E} \left[\left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}; \zeta_k) - \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 \right] + \eta^2 \left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 \quad (54)$$

$$= \eta^2 \left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 + \eta^2 \mathbb{E} \left[\left\| \frac{1}{K} \sum_{k=1}^K \left(1 + \frac{4\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\bar{\theta}^{(t,0)}) - r_{k'}(\bar{\theta}^{(t,0)})) \right) (\nabla L_k(\theta_k^{(t,\tau)}; \zeta_k) - \nabla L_k(\theta_k^{(t,\tau)})) \right\|^2 \right] \quad (55)$$

$$\stackrel{(b)}{=} \eta^2 \frac{1}{K^2} \sum_{k=1}^K \left| 1 + \frac{4\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} (r_k(\bar{\theta}^{(t,0)}) - r_{k'}(\bar{\theta}^{(t,0)})) \right| \mathbb{E} \left[\left\| \nabla L_k(\theta_k^{(t,\tau)}; \zeta_k) - \nabla L_k(\theta_k^{(t,\tau)}) \right\|^2 \right] + \eta^2 \left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 \quad (56)$$

$$\stackrel{(c),(d)}{\leq} \eta^2 (1 + 4\lambda\Gamma)^2 \frac{\sigma^2}{K} + \eta^2 \left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 \quad (57)$$

Here (a) is because for any random vector X , we have $\mathbb{E}[\|X\|^2] = \mathbb{E}[\|X - \mathbb{E}[X]\|^2] + \|\mathbb{E}[X]\|^2$, (b) is due to the fact that $\mathbb{E}[\|\sum_{k=1}^K x_k - \mathbb{E}[x_k]\|^2] = \sum_{k=1}^K \mathbb{E}[\|x_k - \mathbb{E}[x_k]\|^2]$ for all $\{x_k\}_{k=1}^K$ which are independent (c) is due to $\forall \theta \in \mathcal{H} : \left| 1 + \frac{\lambda}{K-1} \sum_{k=1}^K (r_k(\theta) - r_k(\theta')) \right| \leq (1 + \lambda\Gamma)$ and (d) is because of the bounded variance of stochastic gradients of L_k : $\mathbb{E}[\|\nabla L_k(\theta; \zeta_k) - \nabla L_k(\theta)\|^2] \leq \sigma^2$.

Thus:

$$\mathbb{E}[F(\bar{\theta}^{(t,\tau+1)})] \quad (58)$$

$$= \mathbb{E}[F(\bar{\theta}^{(t,\tau)})] - \eta \langle \nabla F(\bar{\theta}^{(t,\tau)}), \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \rangle + \frac{(1 + 4\lambda\Gamma)\beta + 8\lambda B^2}{2} \eta^2 \left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 + \frac{(1 + 4\lambda\Gamma)\beta + 8\lambda B^2}{2} \eta^2 (1 + 4\lambda\Gamma)^2 \frac{\sigma^2}{K} \quad (59)$$

$$\stackrel{(e)}{=} \mathbb{E}[F(\bar{\theta}^{(t,\tau)})] - \frac{\eta}{2} \left[\|\nabla F(\bar{\theta}^{(t,\tau)})\|^2 + \left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 - \left\| \nabla F(\bar{\theta}^{(t,\tau)}) - \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 \right] + \frac{(1 + 4\lambda\Gamma)\beta + 8\lambda B^2}{2} \eta^2 \left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 + \frac{(1 + 4\lambda\Gamma)\beta + 8\lambda B^2}{2} \eta^2 (1 + 4\lambda\Gamma)^2 \frac{\sigma^2}{K} \quad (60)$$

$$= \mathbb{E}[F(\bar{\theta}^{(t,\tau)})] - \frac{\eta}{2} \|\nabla F(\bar{\theta}^{(t,\tau)})\|^2 + \frac{\eta}{2} \left\| \nabla F(\bar{\theta}^{(t,\tau)}) - \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 - \frac{\eta - \eta^2((1 + 4\lambda\Gamma)\beta + 8\lambda B^2)}{2} \left\| \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) \right\|^2 + \frac{(1 + 4\lambda\Gamma)\beta + 8\lambda B^2}{2} \eta^2 (1 + 4\lambda\Gamma)^2 \frac{\sigma^2}{K} \quad (61)$$

$$\begin{aligned}
 &\leq \mathbb{E}[F(\bar{\theta}^{(t,\tau)})] - \frac{\eta}{2} \|\nabla F(\bar{\theta}^{(t,\tau)})\|^2 + \frac{\eta}{2} \|\nabla F(\bar{\theta}^{(t,\tau)}) - \frac{1}{K} \sum_{k=1}^K \nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)})\|^2 \\
 &\quad + \frac{(1+4\lambda\Gamma)\beta + 8\lambda B^2}{2} \eta^2 (1+4\lambda\Gamma)^2 \frac{\sigma^2}{K} \quad \text{(This is for the choice of } \eta \leq \frac{1}{(1+4\lambda\Gamma)L+8\lambda B^2}\text{)} \\
 &\stackrel{(49)}{\leq} \mathbb{E}[F(\bar{\theta}^{(t,\tau)})] - \frac{\eta}{2} \|\nabla F(\bar{\theta}^{(t,\tau)})\|^2 + 4\eta^3 I^2 (1+4\lambda)^2 B^2 \left[(1+4\lambda\Gamma)^2 \beta^2 + 32\lambda^2 B^4 \right] \\
 &\quad + \frac{(1+4\lambda\Gamma)\beta + 8\lambda B^2}{2} \eta^2 (1+4\lambda\Gamma)^2 \frac{\sigma^2}{K}. \tag{62}
 \end{aligned}$$

(e) is using $\|a - b\|^2 = \|a\|^2 + \|b\|^2 - 2\langle a, b \rangle$.

Rearranging and dividing both sides by $\frac{\eta}{2}$ and summing over $t \in \{1, \dots, T\}$ synchronization rounds and $\tau \in \{1, \dots, I\}$ local steps, and finally dividing by TI :

$$\begin{aligned}
 \mathbb{E}[\|\nabla F(\bar{\theta}^{(t,\tau)})\|^2] &\leq \frac{2}{\eta} [\mathbb{E}[F(\bar{\theta}^{(t,\tau)})] - \mathbb{E}[F(\bar{\theta}^{(t,\tau+1)})]] \\
 &\quad + 2\eta^2 I^2 (1+4\lambda)^2 B^2 \left[(1+4\lambda\Gamma)^2 \beta^2 + 32\lambda^2 B^4 \right] \\
 &\quad + ((1+4\lambda\Gamma)\beta + 8\lambda B^2) (1+4\lambda\Gamma)^2 \eta \frac{\sigma^2}{K} \tag{63}
 \end{aligned}$$

$$\begin{aligned}
 \frac{1}{TI} \sum_{t=1}^T \sum_{\tau=1}^I \mathbb{E}[\|\nabla F(\bar{\theta}^{(t,\tau)})\|^2] &\leq 2 \frac{1}{\eta TI} \mathbb{E}[F(\bar{\theta}^{(1,1)})] - \mathbb{E}[F(\bar{\theta}^{(T,I)})] \\
 &\quad + 2\eta^2 I^2 (1+4\lambda)^2 B^2 \left[(1+4\lambda\Gamma)^2 \beta^2 + 32\lambda^2 B^4 \right] \\
 &\quad + ((1+4\lambda\Gamma)\beta + 8\lambda B^2) (1+4\lambda\Gamma)^2 \eta \frac{\sigma^2}{K} \tag{64}
 \end{aligned}$$

$$\begin{aligned}
 &\stackrel{F^* := \arg \min_{\theta} F(\theta)}{\leq} 2 \frac{1}{\eta TI} (F(\bar{\theta}^{(1,1)}) - F^*) \\
 &\quad + 2\eta^2 I^2 (1+4\lambda)^2 B^2 \left[(1+4\lambda\Gamma)^2 \beta^2 + 32\lambda^2 B^4 \right] \\
 &\quad + ((1+4\lambda\Gamma)\beta + 8\lambda B^2) (1+4\lambda\Gamma)^2 \eta \frac{\sigma^2}{K}. \quad \square
 \end{aligned}$$

Theorem 2 (Convergence to a solution of federated learning). *Let $\theta_k^{(t,\tau)}$ refer to the model of client k after t communication rounds and τ local steps and let $\bar{\theta}^{(t,\tau)} := \frac{1}{K} \sum_{k=1}^K \theta_k^{(t,\tau)}$. Let T be the total number of communication rounds and I be the number of local steps between each communication round. Under Assumption 1, for $\eta \leq \frac{1}{(1+4\lambda\Gamma)\beta + 8\lambda B^2}$, the sequence of models $\{\bar{\theta}^{(t,\tau)}\}_{t \geq 0, \tau \geq 0}$ generated by Algorithm 1 satisfies:*

$$\begin{aligned}
 \frac{1}{TI} \sum_{t=1}^T \sum_{\tau=1}^I \mathbb{E}[\|\nabla L(\bar{\theta}^{(t,\tau)})\|^2] &\leq 2 \frac{1}{\eta TI} (L(\bar{\theta}^{(1,1)}) - L^*) + \underbrace{32\lambda^2 \Gamma^2 B^2}_{\text{neighborhood of the solution relative to the heterogeneity}} + \eta \frac{\sigma^2}{K} \xi_2 \tag{65} \\
 &\quad + 8\beta^2 \eta^2 I^2 (1+4\lambda\Gamma)^2 B^2,
 \end{aligned}$$

with $\xi_2 := ((1+4\lambda\Gamma)\beta + 8\lambda B^2) (1+4\lambda\Gamma)^2$.

If we further assume that $L(\theta)$ is μ -Polyak-Łojasiewicz (PL), that is $\forall \theta \in \mathcal{H} : \frac{1}{2} \|\nabla L(\theta)\| \geq \mu(L(\theta) - L^*)$, then we have that:

$$\begin{aligned}
 \frac{1}{TI} \sum_{t=1}^T \sum_{\tau=1}^I \mathbb{E}[L(\bar{\theta}^{(t,\tau)}) - L^*] &\leq 4 \frac{\mu}{\eta TI} (L(\bar{\theta}^{(1,1)}) - L^*) \\
 &\quad + 2\eta \frac{\sigma^2}{K} \xi_2 + 16\beta^2 \eta^2 I^2 (1+4\lambda\Gamma)^2 B^2 + \underbrace{62\mu\lambda^2 \Gamma^2 B^2}_{\text{Loss in utility}}. \tag{66}
 \end{aligned}$$

The main difference from the proof of Theorem 1 is the bound on the difference between the applied gradient $\nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)})$ and the gradient of the original federated learning problem $\nabla L_k(\bar{\theta}^{(t,\tau)})$:

$$\begin{aligned} & \|\nabla \tilde{F}_k(\theta_k^{(t,\tau)}, \bar{\theta}^{(t,0)}) - \nabla L_k(\bar{\theta}^{(t,\tau)})\|^2 \\ &= \left\| \left(1 + 4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} [r_k(\bar{\theta}^{(t,0)}) - r_{k'}(\bar{\theta}^{(t,0)})] \right) \nabla L_k(\theta_k^{(t,\tau)}) - \nabla L_k(\bar{\theta}^{(t,\tau)}) \right\|^2 \end{aligned} \quad (67)$$

$$\begin{aligned} & \leq 2 \underbrace{\|\nabla L_k(\theta_k^{(t,\tau)}) - \nabla L_k(\bar{\theta}^{(t,\tau)})\|^2}_{\text{Controllable using smoothness}} \\ & + 2 \left\| \left(4 \frac{\lambda}{K-1} \sum_{1 \leq k' \neq k \leq K} [r_k(\bar{\theta}^{(t,0)}) - r_{k'}(\bar{\theta}^{(t,0)})] \right) \nabla L_k(\theta_k^{(t,\tau)}) \right\|^2 \end{aligned} \quad (68)$$

$$\begin{aligned} & \|\nabla L_k(\theta)\| \leq B \\ & \leq 2\beta^2 \|\theta_k^{(t,\tau)} - \bar{\theta}^{(t,\tau)}\|^2 + \frac{32\lambda^2}{(K-1)^2} \left| \left(\sum_{1 \leq k' \neq k \leq K} [r_k(\bar{\theta}^{(t,0)}) - r_{k'}(\bar{\theta}^{(t,0)})] \right) \right|^2 B^2 \end{aligned} \quad (69)$$

$$\begin{aligned} & \stackrel{\text{Lemma 4}}{\leq} 8\beta^2 \eta^2 I^2 (1 + 4\lambda\Gamma)^2 B^2 + \frac{32\lambda^2}{(K-1)^2} \left| \left(\sum_{1 \leq k' \neq k \leq K} [r_k(\bar{\theta}^{(t,0)}) - r_{k'}(\bar{\theta}^{(t,0)})] \right) \right|^2 B^2 \end{aligned} \quad (70)$$

$$\begin{aligned} & \leq 8\beta^2 \eta^2 I^2 (1 + 4\lambda\Gamma)^2 B^2 + \frac{32\lambda^2}{K-1} \sum_{1 \leq k' \neq k \leq K} \underbrace{\left| r_k(\bar{\theta}^{(t,0)}) - r_{k'}(\bar{\theta}^{(t,0)}) \right|^2}_{\leq \Gamma^2} B^2 \end{aligned} \quad (71)$$

$$\leq 32\lambda^2 \Gamma^2 B^2 + 8\beta^2 \eta^2 I^2 (1 + 4\lambda\Gamma)^2 B^2. \quad (72)$$

The results in Theorem 2 follows after applying the smoothness of L_k between two consecutive virtual models $\bar{\theta}^{(t,\tau)}$ and $\bar{\theta}^{(t,\tau+1)}$, similarly as in the proof of Theorem 1.

B ADDITIONAL EXPERIMENTAL DETAILS AND RESULTS

B.1 Approximation of L_k^*

In the implementation of EAGLE, we start with an initialization phase in which clients run local training with the global model architecture and hyperparameters that are shared by the server. In practice, the client already has an approximation of L_k^* from previous local training before joining federated learning. Each client runs multiple epochs of SGD until one of the stopping criteria is met, the maximum number of allowed epochs is reached, or the training loss history curve flattens. This heuristic convergence test is not guaranteed to reach the global optimum, especially in nonconvex cases. For the experiments on linear models, we use a logistic regression model with nonseparable data, resulting in a strongly convex local objective and thus a single global optimum; therefore, our convergence check works in this case. We leave more elaborate strategies to approximate L_k^* for future work.

B.2 Dirichlet Splitting

Dirichlet splitting consists of generating a probability vector with the size of the number of clients using the Dirichlet distribution with a given parameter α . The parameter α controls the level of heterogeneity or uniformity in the generated probability vector, with $\alpha \rightarrow 0$ resulting in very heterogeneous probability vectors and $\alpha \rightarrow \infty$ in very uniform ones. To generate a data split across 10 clients, we generate probability vectors for each target value of $\{0, 1, \dots, 61\}$ with the size of the number of clients for a given α parameter. Following the the generated probability vectors we partition the data of each target value across clients. No data points are repeated in multiple clients and the probability vectors are generated independently.

B.3 Computational Resources

All experiments have been run by simulating federated learning on one machine (no communication between nodes). The machine has a NVIDIA A10 GPU chip with a Linux operating system. The results can be reproduced with the seeds $[0, 42, 100, 200]$ for model initialization and the splitting of the data across clients. All experiments have been run for 10000 epochs with full batch gradients to ensure convergence of all methods.

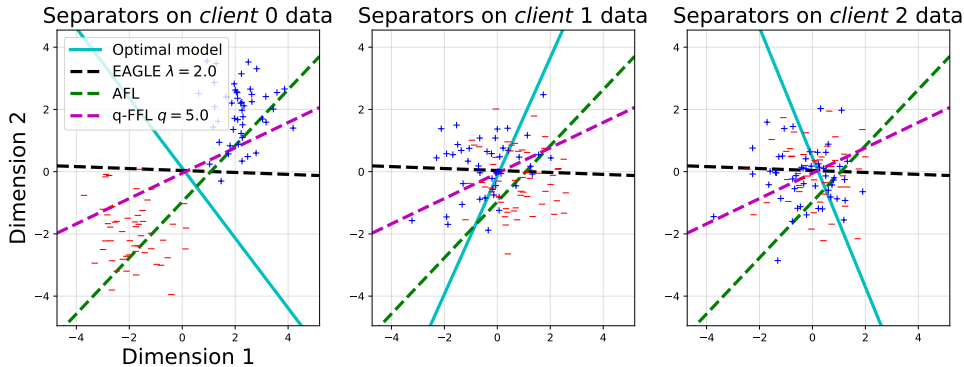

Figure 5: Synthetic data distributions of the three clients. Rotating data resulted in client 1 and client 2 sharing the same optimal separator which is different than the one for client 0. This difference results in conflicting gradient directions between local optimizers for different clients.

Figure 6: Training behavior on the synthetic dataset. *AFL* and *q-FFL* increase the training loss of client 0 to match that of client 2, but fail to balance the losses of client 1 and client 2, which share the same optimal model despite differing in data separability.

B.4 Models and Hyperparameters

We learn a linear model and a convolutional layer neural network that classifies an image $x \in \mathbb{R}^{784}$ as a single label $y \in [62]$. We use SGD for local steps with learning rates tuned for each algorithm based on preliminary experiments. For *q-FFL*, we use a grid search on q in $\{0.001, 0.01, 0.1, 1, 2, 5, 10\}$ as proposed in the original work (Li et al., 2020b). We run *EAGLE* with multiple values of λ in $\{0.1, 0.3, 0.5, 0.7, 1.0, 2.0, 3.0, 5.0\}$ to illustrate the utility-fairness trade-off.

B.5 Additional Results on Synthetic Data

Figure 6 shows the optimization behavior of each algorithm, illustrating that clients with lower optimal local losses can be disadvantaged when enforcing *loss parity*.

B.6 Additional Results on EMNIST

This section presents results on enforcing loss gaps parity while preserving utility for *EAGLE* and the impact of the hyperparameter λ . Tables 4, 5, 6 and 7 report the results for the linear model, while Tables 8, 9, 10 and 11 display the outcomes for the CNN model. Across both architectures, we observe that the results remain consistent with the main analysis regardless of the heterogeneity level introduced, confirming the generalizability of our conclusions in different heterogeneity levels.
