

# BE AWARE OF THE NEIGHBORHOOD EFFECT: MODELING SELECTION BIAS UNDER INTERFERENCE FOR RECOMMENDATION

**Anonymous authors**

Paper under double-blind review

## ABSTRACT

Selection bias in recommender system arises from the recommendation process of system filtering and the interactive process of user selection. Many previous studies have focused on addressing selection bias to achieve unbiased learning of the prediction model, but ignore the fact that potential outcomes for a given user-item pair may vary with the treatments assigned to other user-item pairs, named neighborhood effect. To fill the gap, this paper formally formulates the neighborhood effect as an interference problem from the perspective of causal inference, and introduces a treatment representation to capture the neighborhood effect. On this basis, we propose a novel ideal loss that can be used to deal with selection bias in the presence of neighborhood effect. We further develop two new estimators for estimating the proposed ideal loss. We theoretically establish the connection between the proposed and previous debiasing methods ignoring the neighborhood effect, showing that the proposed methods can achieve unbiased learning when both selection bias and neighborhood effects are present, while the existing methods are biased. Extensive semi-synthetic and real-world experiments are conducted to demonstrate the effectiveness of the proposed methods.

## 1 INTRODUCTION

Selection bias is widespread in recommender system (RS) and challenges the prediction of users' true preferences (Chen et al., 2021b; Wu et al., 2022), which arises from the recommendation process of system filtering and the interactive process of user selection (Marlin and Zemel, 2009; Huang et al., 2022). For example, in the rating prediction task, selection bias happens in explicit feedback data as users are free to choose which items to rate, so that the observed ratings are not a representative sample of all ratings (Steck, 2010). In the post-click conversion rate (CVR) prediction task, selection bias happens due to conventional CVR models are trained with samples of clicked impressions while utilized to make inference on the entire space with samples of all impressions (Ma et al., 2018; Zhang et al., 2020; Guo et al., 2021; Dai et al., 2022; Wang et al., 2022).

Inspired by the causal inference literature (Imbens and Rubin, 2015), many studies have proposed unbiased estimators for eliminating the selection bias, such as inverse propensity scoring (IPS) (Schnabel et al., 2016), self-normalized IPS (SNIPS) (Swaminathan and Joachims, 2015), and doubly robust (DR) methods (Wang et al., 2019; Dai et al., 2022; Chen et al., 2021a; Li et al., 2023d). Given the features of a user-item pair, these methods first estimate the probability of observing that user rating or clicking on the item, called propensity. Then the inverse of the propensity is used to weight the observed samples to achieve unbiased estimates of the ideal loss.

However, the theoretical guarantees of the previous methods are all established under the Stable Unit Treatment Values Assumption (SUTVA) (Rubin, 1980), which requires that the potential outcomes for one user-item pair do not vary with the treatments assigned to other user-item pairs (also known as no interference or no neighborhood effect), as shown in Figure 1(a). In fact, such assumption can hardly be satisfied in real-world scenarios. For example, a user's rating on an item can be easily influenced by other users' ratings on that item, as well as a user's clicking on an item might facilitate other users' clicking and purchasing of that item (Zheng et al., 2021; Chen et al., 2021c). Figure 1(b) shows a general causal diagram in the presence of interference in debiased recommendation.

Figure 1: Causal diagrams of the existing debiasing methods under no interference assumption (left), and the proposed method taking into account the presence of interference (right), where  $x_{u,i}$ ,  $o_{u,i}$ , and  $r_{u,i}$  denote the confounder, treatment, and outcome of user-item pair  $(u, i)$ , respectively. In the presence of interference,  $\mathcal{N}_{(u,i)}$  and  $\mathcal{N}_{-(u,i)}$  denote the other user-item pairs affecting and not affecting  $(u, i)$ , respectively, and  $g_{u,i}$  denotes the treatment representation to capture the interference.

To fill this gap, in this paper, we first formulate the debias problem in Figure 1(b) from the perspective of causal inference, and refine the definition of potential outcomes to be compatible in the presence of interference. **In addition, we introduce** a learnable treatment representation to capture such interference. Based on the refined potential outcome and treatment representation, we propose a novel ideal loss that can effectively evaluate the performance of the prediction model when both selection bias and neighborhood effect are present. We then propose two new estimators for estimating the proposed ideal loss, named neighborhood inverse propensity score (N-IPS) and neighborhood doubly robust (N-DR), respectively. Theoretical analysis shows that the proposed N-IPS and N-DR estimators can achieve unbiased learning in the presence of both selection bias and neighborhood effect, while the previous debiasing estimators cannot result in unbiased learning without imposing extra strong assumptions. Extensive semi-synthetic and real-world experiments are conducted to demonstrate the effectiveness of the proposed methods for eliminating the selection bias under interference.

## 2 PRELIMINARIES: PREVIOUS SELECTION BIAS FORMULATION

Let  $u \in \mathcal{U}$  and  $i \in \mathcal{I}$  be a user and an item,  $x_{u,i}$ ,  $o_{u,i}$ , and  $r_{u,i}$  be the feature, treatment (e.g., exposure), and feedback (e.g., conversion) of the user-item pair  $(u, i)$ , where  $o_{u,i}$  equals 1 or 0 represents whether the item  $i$  is exposed to user  $u$  or not. Let  $\mathcal{D} = \{(u, i) | u \in \mathcal{U}, i \in \mathcal{I}\}$  be the set of all user-item pairs. Using the potential outcome framework (Rubin, 1974; Neyman, 1990), let  $r_{u,i}(1)$  be the potential feedback that would be observed if item  $i$  had been exposed to user  $u$  (i.e.,  $o_{u,i}$  had been set to 1). The potential feedback  $r_{u,i}(1)$  is observed only when  $o_{u,i} = 1$ , otherwise it is missing. Then ignoring the missing  $r_{u,i}(1)$  and training the prediction model directly with the exposed data suffers from selection bias, since the exposure is not random and is affected by various factors.

In the absence of neighborhood effects, the potential feedback  $r_{u,i}(1)$  represents the user’s preference by making intervention  $o_{u,i} = 1$ . To predict  $r_{u,i}(1)$  for all  $(u, i) \in \mathcal{D}$ , let  $\hat{r}_{u,i} \triangleq f_{\theta}(x_{u,i})$  be a prediction model parameterized with  $\theta$ . Denote  $\hat{\mathbf{R}} \in \mathbb{R}^{|\mathcal{U}| \times |\mathcal{I}|}$  as the predicted potential feedback matrix with each element being  $\hat{r}_{u,i}$ . If all the potential feedback  $\{r_{u,i}(1) : (u, i) \in \mathcal{D}\}$  were observed, the ideal loss for training the prediction model  $\hat{r}_{u,i}$  is formally defined as

$$\mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}}) = |\mathcal{D}|^{-1} \sum_{(u,i) \in \mathcal{D}} \delta(\hat{r}_{u,i}, r_{u,i}(1)), \quad (1)$$

where  $\delta(\cdot, \cdot)$  is a pre-defined loss function, e.g., the squared loss  $(r_{u,i}(1) - \hat{r}_{u,i})^2$ . However, since  $r_{u,i}(1)$  is missing when  $o_{u,i} = 0$ , the ideal loss cannot be computed directly from observational data. To tackle this problem, many debiasing methods are developed to address the selection bias by establishing unbiased estimators of  $\mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}})$ , such as error imputation based (EIB) method (Hernández-Lobato et al., 2014), inverse propensity scoring (IPS) method (Schnabel et al., 2016), self-normalized IPS (SNIPS) method (Swaminathan and Joachims, 2015), and doubly robust (DR) methods (Wang et al., 2019; Dai et al., 2022; Chen et al., 2021a; Li et al., 2023d). We summarize the causal parameter of interest and the corresponding estimation methods in the previous studies as follows.

- For the causal parameter of interest, previous studies assume the targeted user preference  $r_{u,i}(o_{u,i} = 1)$  depends only on the treatment status  $o_{u,i} = 1$ . Then the ideal loss is defined using the sample average of  $\delta(\hat{r}_{u,i}, r_{u,i}(o_{u,i} = 1))$ .
- For the methods of estimating the causal parameter of interest, previous work have made extensive efforts to estimate the probability  $\mathbb{P}(o_{u,i} = 1 \mid x_{u,i})$ , called propensity, i.e., the probability of user  $u$  rate the item  $i$  given the features  $x_{u,i}$ . Then the existing IPS and DR methods use the inverse of the propensity for weighting the observed samples.

Nevertheless, we argue that both the causal parameter and the corresponding estimation methods in the previous studies **lead** to the failure when eliminating the selection bias under interference.

- (Section 3) For the causal parameter of interest, as shown in Figure 1(b), in the presence of interference, both the treatment status  $o_{u,i}$  and the treatment statuses  $\mathbf{o}_{\mathcal{N}_{(u,i)}}$  would affect the targeted user preference  $r_{u,i}(o_{u,i}, \mathbf{o}_{\mathcal{N}_{(u,i)}})$ , instead of  $r_{u,i}(o_{u,i})$  in the previous studies.
- (Section 4) For the estimation methods of the causal parameter of interest, as shown in Figure 1(b), when performing propensity-based reweighting methods, both  $o_{u,i}$  and  $\mathbf{o}_{\mathcal{N}_{(u,i)}}$  from its neighbors should be considered as treatments of user-item pair  $(u, i)$ . Therefore, the propensity should be modeled as  $\mathbb{P}(o_{u,i} = 1, \mathbf{o}_{\mathcal{N}_{(u,i)}} \mid x_{u,i})$  instead of  $\mathbb{P}(o_{u,i} = 1 \mid x_{u,i})$  in previous studies, which motivates us to design new IPS and DR estimators under interference.

### 3 MODELING SELECTION BIAS UNDER NEIGHBORHOOD EFFECT

In this section, we take the neighborhood effect in RS as an interference problem in causal inference and introduce a treatment representation to capture the neighborhood effect. Then, we propose a novel ideal loss when both selection bias and neighborhood effects are present.

#### 3.1 BEYOND “NO INTERFERENCE” ASSUMPTION IN PREVIOUS STUDIES

In the presence of neighborhood effect, the value of  $r_{u,i}(1)$  depends on not only the user’s preference but also the neighborhood effect, therefore we cannot distinguish the influence of user preference and the neighborhood effect, even if all the potential outcomes  $\{r_{u,i}(1) : (u, i) \in \mathcal{D}\}$  were known. Conceptually, the neighborhood effect will cause the value of  $r_{u,i}(1)$  relying on the exposure status  $o_{u',i'}$  and the feedback  $r_{u',i'}$  for some other user-item pairs  $(u', i') \neq (u, i)$ .

We say that interference exists when a treatment on one unit has an effect on the outcome of another unit (Ogburn and VanderWeele, 2014; Forastiere et al., 2021; Sävje et al., 2021), due to the social or physical interaction among units. Previous debiasing methods rely on “no interference” assumption, which requires the potential outcomes of a unit are not affected by the treatment status of the other units. Nevertheless, such assumption can hardly be satisfied in real-world recommendation scenarios.

#### 3.2 PROPOSED CAUSAL PARAMETER OF INTEREST UNDER INTERFERENCE

Let  $\mathbf{o} = (o_{1,1}, \dots, o_{|\mathcal{U}|, |\mathcal{I}|})$  be the vector of exposures of all user-item pairs. For each  $(u, i) \in \mathcal{D}$ , we define a partition of  $\mathbf{o} = (o_{u,i}, \mathbf{o}_{\mathcal{N}_{(u,i)}}, \mathbf{o}_{\mathcal{N}_{-(u,i)}})$ , where  $\mathcal{N}_{(u,i)}$  is all the user-item pairs affecting  $(u, i)$ , called the *neighbors* of  $(u, i)$ , and  $\mathcal{N}_{-(u,i)}$  is all the user-item pairs not affecting  $(u, i)$ . When the feedback  $r_{u,i}$  is further influenced by the neighborhood exposures  $\mathbf{o}_{\mathcal{N}_{(u,i)}}$ , then the potential feedback of  $(u, i)$  should be defined as  $r_{u,i}(o_{u,i}, \mathbf{o}_{\mathcal{N}_{(u,i)}})$  to account for the neighbourhood effect.

However, if we take  $(o_{u,i}, \mathbf{o}_{\mathcal{N}_{(u,i)}})$  as the new treatment directly, it would be a high-dimensional sparse vector when the dimension of  $\mathbf{o}_{\mathcal{N}_{(u,i)}}$  is high and the number of exposed neighbors is limited. To address this problem and capture the neighborhood effect effectively, we make an assumption on the interference mechanism leveraging the idea of representation learning (Johansson et al., 2016).

**Assumption 1** (Neighborhood treatment representation). *There exists a representation vector  $\phi : \{0, 1\}^{|\mathcal{N}_{(u,i)}|} \rightarrow \mathcal{G}$ , if  $\phi(\mathbf{o}_{\mathcal{N}_{(u,i)}}) = \phi(\mathbf{o}'_{\mathcal{N}_{(u,i)}})$ , then  $r_{u,i}(o_{u,i}, \mathbf{o}_{\mathcal{N}_{(u,i)}}) = r_{u,i}(o_{u,i}, \mathbf{o}'_{\mathcal{N}_{(u,i)}})$ .*

The above assumption implies that the value of  $r_{u,i}(o_{u,i}, \mathbf{o}_{\mathcal{N}_{(u,i)}})$  depends on  $\mathbf{o}_{\mathcal{N}_{(u,i)}}$  through a specific treatment representation  $\phi(\cdot)$  that summarizes the neighborhood effect. Denote  $\mathbf{g}_{u,i}$  as  $\phi(\mathbf{o}_{\mathcal{N}_{(u,i)}})$ , then we have  $r_{u,i}(o_{u,i}, \mathbf{o}_{\mathcal{N}_{(u,i)}}) = r_{u,i}(o_{u,i}, \mathbf{g}_{u,i})$  under Assumption 1, i.e., the feedback of  $(u, i)$  under individual exposure  $o_{u,i}$  and treatment representation  $\mathbf{g}_{u,i}$ .

We now propose ideal loss under neighborhood effect with treatment representation level  $\mathbf{g} \in \mathcal{G}$  as

$$\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g}) = |\mathcal{D}|^{-1} \sum_{(u,i) \in \mathcal{D}} \delta(\hat{r}_{u,i}, r_{u,i}(o_{u,i} = 1, \mathbf{g})),$$

and the final ideal loss summarizes various neighborhood effects  $\mathbf{g} \in \mathcal{G}$  is constructed as

$$\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}) = \int \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g})\pi(\mathbf{g})d\mathbf{g}, \quad (2)$$

where  $\pi(\mathbf{g})$  is a pre-specified probability density function of  $\mathbf{g}$ .

The proposed  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$  forces the prediction model  $\hat{r}_{u,i}$  to perform well across varying treatment representation levels  $\mathbf{g} \in \mathcal{G}$ . Thus,  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$  is expected to control the extra bias arises from the neighborhood effect. In comparison, the neighborhood effect and self interest of users are intertwined in  $\mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}})$ . In addition,  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$  is very flexible due to the free choice of  $\pi(\mathbf{g})$ . Intuitively, the choice of  $\pi(\mathbf{g})$  depends on the target population that we want to make predictions on. Consider an extreme case of no neighborhood effects, this corresponds to  $\mathbf{g}_{u,i} = 0$  for all user-item pairs. In such a case, we can write  $r_{u,i}(1, 0)$  as  $r_{u,i}(1)$  and  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$  would reduce to  $\mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}})$ .

## 4 UNBIASED ESTIMATION AND LEARNING UNDER INTERFERENCE

In this section, we first discuss the consequence of ignoring the neighborhood effect, and then propose two novel estimators for the ideal loss in Eq. (2). Moreover, we theoretically analyze the bias, variance, optimal bandwidth, and generalization error bound of the proposed estimators.

Before presenting the proposed debiasing methods under interference, we briefly discuss the identifiability of the ideal loss  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$ . A causal estimand is said to be identifiable if it can be written as a series of quantities that can be estimated from observed data.

**Assumption 2** (Consistency under interference).  $r_{u,i} = r_{u,i}(1, \mathbf{g})$  if  $o_{u,i} = 1$  and  $\mathbf{g}_{u,i} = \mathbf{g}$ .

**Assumption 3** (Unconfoundedness under interference).  $r_{u,i}(1, \mathbf{g}) \perp\!\!\!\perp (o_{u,i}, \mathbf{G}_{u,i}) \mid x_{u,i}$ .

These assumptions are common in causal inference to ensure the identifiability of causal effects. Specifically, Assumption 2 implies that  $r_{u,i}(1, \mathbf{g})$  is observed only when  $o_{u,i} = 1$  and  $\mathbf{g}_{u,i} = \mathbf{g}$ . Assumption 3 indicates that there is no unmeasured confounder that affects both  $r_{u,i}$  and  $(o_{u,i}, \mathbf{g}_{u,i})$ . The following Theorem 1 gives the identifiability of the proposed ideal loss. Let  $\mathbb{E}$  denote the expectation on the target population  $\mathcal{D}$ , and  $p(\cdot)$  denotes the probability density function of  $\mathbb{P}$ .

**Theorem 1** (Identifiability). *Under Assumptions 1–3,  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$  is identifiable.*

### 4.1 EFFECT OF IGNORING INTERFERENCE

The widely used ideal loss  $\mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}})$  under no neighborhood effects is generally different from the ideal loss  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$  in the presence of neighborhood effects. Next, we establish the connection between these two loss functions, to deepen the understanding of the methods of considering/ignoring neighborhood effects. For brevity, we let  $\delta_{u,i}(\mathbf{g}) = \delta(\hat{r}_{u,i}, r_{u,i}(1, \mathbf{g}))$  hereafter.

**Theorem 2** (Link to selection bias). *Under Assumptions 1–3,*

(a) *if  $\mathbf{g}_{u,i} \perp\!\!\!\perp o_{u,i} \mid x_{u,i}$ ,  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}) = \mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}})$ .*

(b) *if  $\mathbf{g}_{u,i} \not\perp\!\!\!\perp o_{u,i} \mid x_{u,i}$ ,  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}) - \mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}})$  equals*

$$\int \mathbb{E} \left[ \mathbb{E} \{ \delta_{u,i}(\mathbf{g}) \mid x_{u,i} \} \cdot \left\{ p(\mathbf{g}_{u,i} = \mathbf{g} \mid x_{u,i}) - p(\mathbf{g}_{u,i} = \mathbf{g} \mid x_{u,i}, o_{u,i} = 1) \right\} \right] \pi(\mathbf{g}) d\mathbf{g}.$$

From Theorem 2(a), if the individual and neighborhood exposures are independent conditional on  $x_{u,i}$ , then  $\mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}})$  equals to  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$ , which indicates that the existing debiasing methods neglecting neighborhood effects are also unbiased estimator of  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$ . This is intuitively reasonable since in such a case, the neighborhood effect randomly influences  $o_{u,i}$  conditional on  $x_{u,i}$ , and the effect of neighbors would be smoothed out in an average sense. Theorem 2(b) shows that a bias would arise when  $\mathbf{g}_{u,i} \not\perp\!\!\!\perp o_{u,i} \mid x_{u,i}$ , and the bias mainly depends on the association between  $o_{u,i}$  and  $\mathbf{g}_{u,i}$  conditional on  $x_{u,i}$ , i.e.,  $p(\mathbf{g}_{u,i} = \mathbf{g} \mid x_{u,i} = x) - p(\mathbf{g}_{u,i} = \mathbf{g} \mid x_{u,i} = x, o_{u,i} = 1)$ .

## 4.2 PROPOSED UNBIASED ESTIMATORS

From Eq. (2), to derive an unbiased estimator of  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$ , it suffices to find an unbiased estimator of  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g})$ . If we follow the previous IPS method (Schnabel et al., 2016) and take  $(o_{u,i}, \mathbf{g}_{u,i})$  as a joint treatment, then the IPS estimator of  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g})$  should be  $|\mathcal{D}|^{-1} \sum_{(u,i) \in \mathcal{D}} \mathbb{I}\{o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g}\} \cdot \delta_{u,i}(\mathbf{g}) / p_{u,i}(\mathbf{g})$ , where  $\mathbb{I}(\cdot)$  is an indicator function,  $p_{u,i}(\mathbf{g}) = p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})$  is the propensity score. Clearly, this strategy works if  $\mathbf{g}_{u,i}$  is a binary or multi-valued random variable. However, if  $\mathbf{g}_{u,i}$  has a continuous probability density, the above estimator is numerically infeasible even if theoretically feasible, since almost all  $\mathbb{I}\{o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g}\}$  will be zero in such a case.

To tackle this problem, we propose a novel kernel-smoothing-based neighborhood IPS (N-IPS) estimator of  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g})$ , which is given as

$$\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}|\mathbf{g}) = |\mathcal{D}|^{-1} \sum_{(u,i) \in \mathcal{D}} \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot p_{u,i}(\mathbf{g})},$$

where  $h$  is a bandwidth (smoothing parameter) and  $K(\cdot)$  is a symmetric kernel function (Li and Racine, 2007; Fan and Gijbels, 1996) that satisfies  $\int K(t)dt = 1$  and  $\int tK(t)dt = 0$ . For example, Epanechnikov kernel  $K(t) = 3(1-t^2)\mathbb{I}\{|t| \leq 1\}/4$  and Gaussian kernel  $K(t) = \exp(-t^2/2)/\sqrt{2\pi}$  for  $t \in \mathbb{R}$ . For ease of presentation, we state the results for a scalar  $\mathbf{g}$  in the manuscript. Similar conclusions can be derived for multi-dimensional  $\mathbf{g}$  and we put them in Appendix G.

Similarly, the kernel-smoothing-based neighborhood DR (N-DR) estimator can be constructed by

$$\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}|\mathbf{g}) = |\mathcal{D}|^{-1} \sum_{(u,i) \in \mathcal{D}} \left[ \hat{\delta}_{u,i}(\mathbf{g}) + \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\}}{h \cdot p_{u,i}(\mathbf{g})} \right],$$

where  $\hat{\delta}_{u,i}(\mathbf{g}) = \delta(\hat{r}_{u,i}, m(x_{u,i}, \phi_{\mathbf{g}}))$  is the imputed error of  $\delta_{u,i}(\mathbf{g})$ , and  $m(x_{u,i}, \phi_{\mathbf{g}})$  is an imputation model of  $r_{u,i}(1, \mathbf{g})$ . The imputation model is trained by minimizing the training loss

$$\mathcal{L}_e^{\text{N-DR}}(\hat{\mathbf{R}}|\mathbf{g}) = |\mathcal{D}|^{-1} \sum_{(u,i) \in \mathcal{D}} \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot (\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g}))^2}{h \cdot p_{u,i}(\mathbf{g})}.$$

Then, the corresponding N-IPS and N-DR estimators of  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$  are given as

$$\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}) = \int \mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}|\mathbf{g})\pi(\mathbf{g})d\mathbf{g}, \quad \mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}) = \int \mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}|\mathbf{g})\pi(\mathbf{g})d\mathbf{g}. \quad (3)$$

Next, we show the bias and variance of the proposed N-IPS and N-DR estimators, which relies on a standard assumption in kernel-smoothing estimation (Li and Racine, 2007; Härdle et al., 2004).

**Assumption 4** (Regularity conditions for kernel smoothing). (a)  $h \rightarrow 0$  as  $|\mathcal{D}| \rightarrow \infty$ ; (b)  $|\mathcal{D}|h \rightarrow \infty$  as  $|\mathcal{D}| \rightarrow \infty$ ; (c)  $p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})$  is twice differentiable with respect to  $\mathbf{g}$ .

**Theorem 3** (Bias and Variance of N-IPS and N-DR). Under Assumptions 1–4,

(a) the bias of the N-DR estimator is given as

$$\text{Bias}(\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}})) = \frac{1}{2}\mu_2 \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \right] \pi(\mathbf{g})d\mathbf{g} \cdot h^2 + o(h^2),$$

where  $\mu_2 = \int K(t)t^2dt$ . The bias of N-IPS is provided in Appendix C.

(b) the variance of the N-DR estimator is given as

$$\text{Var}(\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}})) = \frac{1}{|\mathcal{D}|h} \int \psi(\mathbf{g})\pi(\mathbf{g})d\mathbf{g} + o\left(\frac{1}{|\mathcal{D}|h}\right),$$

where  $\psi(\mathbf{g}) = \int \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \bar{K}\left(\frac{\mathbf{g}-\mathbf{g}'}{h}\right) \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \{\delta_{u,i}(\mathbf{g}') - \hat{\delta}_{u,i}(\mathbf{g}')\} \pi(\mathbf{g}')d\mathbf{g}'$  is a bounded function of  $\mathbf{g}$ ,  $\bar{K}(\cdot) = \int K(t)K(\cdot+t)dt$ . The variance of N-IPS is provided in Appendix C.

From Theorem 3(a), the kernel-smoothing-based N-DR estimator has a small bias of order  $O(h^2)$ , which converges to 0 as  $|\mathcal{D}| \rightarrow \infty$  by Assumption 4(a). Theorem 3(b) shows that the variance of the N-DR estimator has a convergence rate of order  $O(1/|\mathcal{D}|h)$ . Notably, the bandwidth  $h$  plays a key role in the bias-variance trade-off of the N-DR estimator: the larger the  $h$ , the larger the bias and the smaller the variance. The following Theorem 4 gives the optimal bandwidth for N-IPS and N-DR.

**Theorem 4** (Optimal bandwidth of N-IPS and N-DR). *Under Assumptions 1-4, the optimal bandwidth for the N-DR estimator in terms of the asymptotic mean-squared error metric is*

$$h_{\text{N-DR}}^* = \left[ \frac{\int \psi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g}}{4|\mathcal{D}| \left( \frac{1}{2} \mu_2 \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i}=1, \mathbf{g}_{u,i}=\mathbf{g} | \mathbf{x}_{u,i})}{\partial \mathbf{g}^2} \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \right] \pi(\mathbf{g}) d\mathbf{g} \right)^2} \right]^{1/5},$$

where  $\psi(\mathbf{g})$  is defined in Theorem 3. The optimal bandwidth for N-IPS is provided in Appendix D

Theorem 4 shows that the optimal bandwidth of N-DR is of order  $O(|\mathcal{D}|^{-1/5})$ . In such a case,

$$\left[ \text{Bias}(\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})) \right]^2 = O(h^4) = O(|\mathcal{D}|^{-4/5}), \quad \text{Var}(\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})) = O\left(\frac{1}{|\mathcal{D}|h}\right) = O(|\mathcal{D}|^{-4/5}),$$

that is, the square of the bias has the same convergence rate as the variance.

#### 4.3 PROPENSITY ESTIMATION METHOD

Different from previous debiasing methods in RS, in the setting of neighborhood effects, the propensity is defined for joint treatment that includes a binary variable  $o_{u,i}$  and a continuous variable  $\mathbf{g}$ . To address this question, we consider a novel method for propensity estimation. Let  $\mathbb{P}^u(\mathbf{g} | o = 1, \mathbf{x})$  be a uniform distribution on  $\mathcal{G}$  and equals  $1/c$  for all feature  $\mathbf{x}$ . Note that

$$\frac{1}{p_{u,i}(\mathbf{g})} = \frac{1}{\mathbb{P}(o = 1 | \mathbf{x}) \mathbb{P}(\mathbf{g} | o = 1, \mathbf{x})} = \frac{c}{\mathbb{P}(o = 1 | \mathbf{x})} \cdot \frac{\mathbb{P}^u(\mathbf{g} | o = 1, \mathbf{x})}{\mathbb{P}(\mathbf{g} | o = 1, \mathbf{x})},$$

where  $\mathbb{P}(o = 1 | \mathbf{x})$  can be estimated by using the existing methods such as naive Bayes and logistic regression with and without a few unbiased ratings, respectively (Schnabel et al., 2016). In addition, to estimate the density ratio  $\mathbb{P}^u(\mathbf{g} | o = 1, \mathbf{x}) / \mathbb{P}(\mathbf{g} | o = 1, \mathbf{x})$ , we first label the samples in the exposed data  $\{(\mathbf{x}_{u,i}, \mathbf{g}_{u,i})\}_{\{(u,i): o_{u,i}=1\}}$  as positive samples ( $L = 1$ ), then uniformly sample treatments  $\mathbf{g}'_{u,i} \in \mathcal{G}$  to generate samples  $\{(\mathbf{x}_{u,i}, \mathbf{g}'_{u,i})\}_{\{(u,i): o_{u,i}=1\}}$  with negative label ( $L = 0$ ).

Since the data generating process ensures that  $\mathbb{P}^u(\mathbf{x} | o = 1) = \mathbb{P}(\mathbf{x} | o = 1)$ , we have

$$\frac{\mathbb{P}^u(\mathbf{g} | o = 1, \mathbf{x})}{\mathbb{P}(\mathbf{g} | o = 1, \mathbf{x})} = \frac{\mathbb{P}^u(\mathbf{x}, \mathbf{g} | o = 1)}{\mathbb{P}(\mathbf{x}, \mathbf{g} | o = 1)} = \frac{\mathbb{P}(\mathbf{x}, \mathbf{g} | L = 0)}{\mathbb{P}(\mathbf{x}, \mathbf{g} | L = 1)} = \frac{\mathbb{P}(L = 1)}{\mathbb{P}(L = 0)} \cdot \frac{\mathbb{P}(L = 0 | \mathbf{x}, \mathbf{g})}{\mathbb{P}(L = 1 | \mathbf{x}, \mathbf{g})},$$

where  $\mathbb{P}(L = l | \mathbf{x}, \mathbf{g})$  for  $l = 0$  or  $1$  can be obtained by modeling  $L$  with  $(\mathbf{x}, \mathbf{g})$ .

#### 4.4 FURTHER THEORETICAL ANALYSIS

We further theoretically analyze the tail bound and generalization error bound of the proposed N-IPS and N-DR estimators. Letting  $\mathcal{F}$  be the hypothesis space of prediction matrices  $\hat{\mathbf{R}}$  (or prediction model  $f_\theta$ ), we define the Rademacher complexity

$$\mathcal{R}(\mathcal{F}) = \mathbb{E}_{\boldsymbol{\sigma} \sim \{-1, +1\}^{|\mathcal{D}|}} \sup_{f_\theta \in \mathcal{F}} \left[ \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \sigma_{u,i} \delta_{u,i}(\mathbf{g}) \right],$$

where  $\boldsymbol{\sigma} = \{\sigma_{u,i} : (u,i) \in \mathcal{D}\}$  is a Rademacher sequence (Mohri et al., 2018).

**Assumption 5** (Boundedness).  $1/p_{u,i}(\mathbf{g}) \leq M_p$ ,  $\delta_{u,i}(\mathbf{g}) \leq M_\delta$ , and  $|\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})| \leq M_{|\delta - \hat{\delta}|}$ .

**Theorem 5** (Uniform Tail Bound of N-IPS and N-DR). *Under Assumptions 1-5 and suppose that  $K(t) \leq M_K$ , then for all  $\hat{\mathbf{R}} \in \mathcal{F}$ , we have with probability at least  $1 - \eta$ ,*

$$\sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}) - \mathbb{E}[\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})] \right| \leq \frac{2M_p M_K}{h} \mathcal{R}(\mathcal{F}) + \frac{5}{2} \frac{M_p M_K M_{|\delta - \hat{\delta}|}}{h} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)}.$$

The uniform tail bound of the N-IPS estimator is provided in Appendix E.

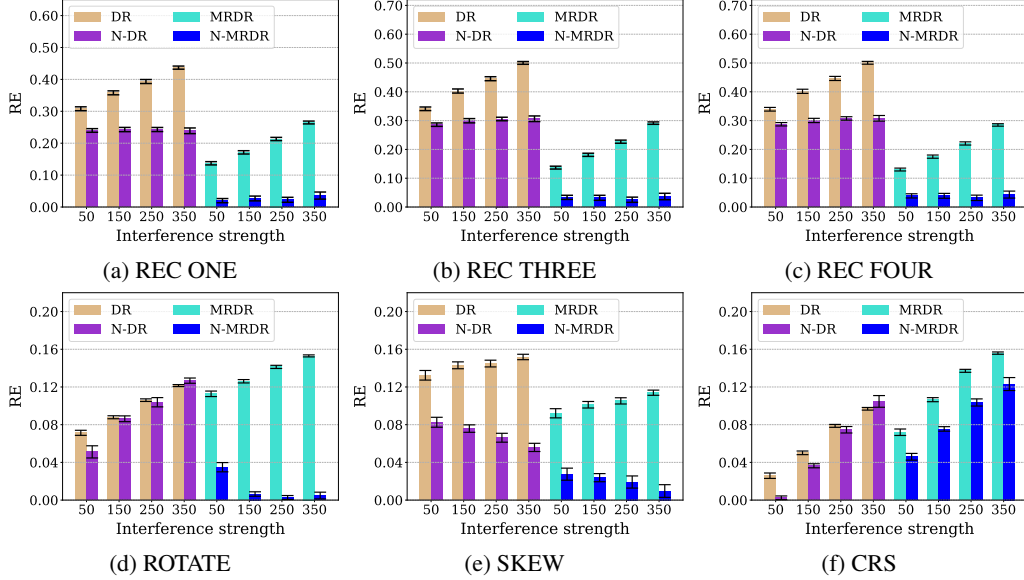

Figure 2: The effect of mask numbers as interference strength on RE on six prediction matrices.

Theorem 5 gives the uniform tail bound of the N-IPS and N-DR estimators. Based on it, we can obtain the generalization error bounds of the prediction model trained by minimizing the N-IPS and N-DR estimators, as shown in the following Corollary 6. Define  $\hat{\mathbf{R}}^\dagger = \arg \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})$ .

**Corollary 6** (Generalization Error Bound of N-IPS and N-DR). *Under the conditions in Theorem 5, we have with probability at least  $1 - \eta$ ,*

$$\begin{aligned} \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^\dagger) &\leq \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}) + \mu_2 M_{|\delta-\hat{\delta}|} \left| \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \right] \pi(\mathbf{g}) d\mathbf{g} \right| \cdot h^2 \\ &\quad + \frac{4M_p M_K}{h} \mathcal{R}(\mathcal{F}) + \frac{5M_p M_K M_{|\delta-\hat{\delta}|}}{h} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)} + o(h^2). \end{aligned}$$

The generalization error bound of the N-IPS estimator is provided in Appendix F.

## 5 SEMI SYNTHETIC EXPERIMENTS

We conduct semi synthetic experiments using MovieLens 100K<sup>1</sup> (**ML-100K**) dataset, focusing on the following two research questions (RQs): **RQ1**. Do the proposed estimators result in more accurate estimation for ideal loss compared to the previous estimators in the presence of neighborhood effect? **RQ2**. How does the neighborhood effect strength affect the estimation accuracy?

**Experimental Setup.** The **ML-100K** dataset contains 100,000 missing-not-at-random (MNAR) ratings from 943 users to 1,682 movies. Different from the previous experimental settings that only consider the selection bias, we further consider the neighborhood effect. Specifically, we denote  $\mathcal{N}_{(u,i)}$  be the historical user and item interactions for the neighbors of  $(u, i)$ , and treatment

representation is chosen from  $g_{u,i} = \mathbb{I}(\sum_{(u',i') \in \mathcal{N}_{(u,i)}} o_{u',i'} \geq c)$  with varying  $c$ . In our experiment,  $c$  is chosen to be the median of all  $\sum_{(u',i') \in \mathcal{N}_{(u,i)}} o_{u',i'}$  for simplicity.

Following the previous studies (Schnabel et al., 2016; Wang et al., 2019; Guo et al., 2021), we first complete the full rating matrix  $\mathbf{R}$  using Matrix Factorization (MF) (Koren et al., 2009), resulting in  $r_{u,i} \in \{1, 2, 3, 4, 5\}$ , and then set propensity  $p_{u,i} = p\alpha^{\max(0, 4-r_{u,i})}$  with  $\alpha = 0.5$  to model MNAR effect (Wang et al., 2019; Guo et al., 2021). Next we compute  $g_{u,i}$  for 100,000 observed MNAR ratings and complete two full rating matrices  $\mathbf{R}^{g=0}$  and  $\mathbf{R}^{g=1}$  with  $r_{u,i}(1, g) \in \{1, 2, 3, 4, 5\}$  using MF, using  $\{(u, i) \mid o_{u,i} = 1, g_{u,i} = 0\}$  and  $\{(u, i) \mid o_{u,i} = 1, g_{u,i} = 1\}$  respectively.

**Experimental Details.** The computation of the ideal loss needs both ground truth rating matrix and prediction rating matrix. Therefore, we first generate the following six prediction matrices  $\hat{\mathbf{R}}$ :

- **ONE:** The predicted rating matrix  $\hat{\mathbf{R}}$  is identical to the true rating matrix, except that  $|\{(u, i) \mid r_{u,i} = 5\}|$  randomly selected true ratings of 1 are flipped to 5. This means half of the predicted fives are true five, and half are true one.
- **THREE:** Same as **ONE**, but flipping true rating of 3.
- **FOUR:** Same as **ONE**, but flipping true rating of 4.
- **ROTATE:** For each predicted rating  $\hat{r}_{u,i} = r_{u,i} - 1$  when  $r_{u,i} \geq 2$ , and  $\hat{r}_{u,i} = 5$  when  $r_{u,i} = 1$ .
- **SKEW:** Predicted  $\hat{r}_{u,i}$  are sampled from the Gaussian distribution  $\mathcal{N}(\mu = r_{u,i}, \sigma = (6 - r_{u,i})/2)$ , and clipped to the interval  $[1, 5]$ .
- **CRS:** Set  $\hat{r}_{u,i} = 2$  if  $r_{u,i} \leq 3$ , otherwise, set  $\hat{r}_{u,i} = 4$ .

Given the way  $c$  is chosen, it is reasonable to assume that each user-item pair in the uniform data has equal probability of having  $g_{u,i} = 0$  and  $g_{u,i} = 1$ . That is,  $\pi(g) = 0.5$  for  $g \in \{0, 1\}$ . Thus,  $\tilde{\mathcal{L}}_{\text{ideal}}(\hat{\mathbf{R}}) = |\mathcal{D}|^{-1} \sum_{(u,i) \in \mathcal{D}} \{\delta(r_{u,i}(1, g=0), \hat{r}_{u,i}) + \delta(r_{u,i}(1, g=1), \hat{r}_{u,i})\}/2$ , where  $\delta(\cdot, \cdot)$  is the mean absolute error (MAE). Following previous studies (Guo et al., 2021; Li et al., 2023b), relative absolute error (RE) is used to measure the accuracy of the estimation, which is defined as  $\text{RE}(\mathcal{L}_{\text{est}}) = |\tilde{\mathcal{L}}_{\text{ideal}}(\hat{\mathbf{R}}) - \mathcal{L}_{\text{est}}(\hat{\mathbf{R}})|/\tilde{\mathcal{L}}_{\text{ideal}}(\hat{\mathbf{R}})$ , where  $\mathcal{L}_{\text{est}}$  denotes the ideal loss estimation by the estimator. The smaller the RE, the higher the estimation accuracy (see Appendix J for more details).

**Performance Analysis.** We take three propensity-based estimators: IPS, DR, and MRDR as baselines (see Section 6 for baselines introduction). The results are shown in Table 1. First, the RE of our estimators is significantly lower compared to the corresponding previous estimators, which indicates that our estimators are able to estimate the ideal loss accurately in the presence of neighborhood effect. In addition, to investigate how the neighborhood effect affect the estimation error, we randomly mask some user rows and item columns before sampling  $o_{u,i}$ , which results in  $p_{u,i} = 0$  for the masked user-item pairs. Since the total number of observed samples is constant, this will result in an increase in the proportion of observed samples with  $g_{u,i} = 1$ , i.e., a stronger neighborhood effect. Figure 2 shows the RE of the estimators. The proposed estimators stably outperform the previous methods in all scenario, which verifies that our proposed estimator is robust to the neighborhood effect.

## 6 REAL-WORLD EXPERIMENTS

**Dataset and Experiment Details.** We verify the effectiveness of the proposed estimators on three real-world datasets: **Coat** contains 6,960 MNAR ratings and 4,640 missing-at-random (MAR) ratings. **Yahoo! R3** contains 311,704 MNAR ratings and 54,000 MAR ratings. In addition, we use a public large-scale fully exposed industrial dataset **KuaiRec**, which contains 4,676,570 video watching ratio records from 1,411 users for 3,327 videos. We pre-specify three ways to measure the neighborhood effect for a user-item pair in MNAR data: (1) the similar user historical behavior, (2) the purchase history of the similar item, and (3) the interaction of similar user and item.  $g_{u,i}$  denotes the neighborhood numbers of the user-item pair, which is a multi-valued representation. We report the best result of our method among the three choice (see Appendix K for more details of datasets and the experimental protocols). MSE, AUC and NDCG@K are used for performance evaluation, where  $K = 5$  for **Coat** and **Yahoo! R3** and  $K = 50$  for **KuaiRec**. We adopt both the Gaussian kernel and Epanechnikov kernel as the kernel function for implementing N-IPS, N-DR-JL, and N-MRDR.

**Baselines.** We take **Matrix Factorization (MF)** (Koren et al., 2009) as the base model and consider the following baselines: **IPS** (Saito et al., 2020; Schnabel et al., 2016), **SNIPS** (Schnabel et al., 2016), **ASIPS** (Saito, 2020), **DAMF** (Saito and Nomura, 2019), **CVIB** (Wang et al., 2020), **DR** (Saito, 2020), **DIB** (Liu et al., 2021), **TDR** (Li et al., 2023b), **DR-BIAS** (Dai et al., 2022), **DR-MSE** (Dai et al., 2022), **Stable-DR** (Li et al., 2023d) and **MR** (Li et al., 2023a). In addition, we also consider the following baseline based on joint learning: **DR-JL** (Wang et al., 2019), **MRDR-JL** (Guo et al., 2021) and **TDR-JL** (Li et al., 2023b). Following previous studies (Schnabel et al., 2016; Wang et al., 2019), for all baseline methods requiring propensity estimation, we adopt naive Bayes (NB) method using 5% MAR ratings for training the propensity model. For our proposed methods, we also adopt logistic regression (LR) to estimate the propensities without the usage of MAR ratings.

**Real-World Debiasing Performance.** Table 2 shows the performance of the baselines and our methods on three datasets. Compared with the Naive method, the debiasing method significantly outperforms the Naive method. In particular, the proposed methods perform similarly in the case of adopting Gaussian kernel or Epanechnikov kernel, and are able to stably outperform the baseline methods in all metrics. This is because that the kernel function in the estimator can provide more smooth weights in the proposed propensity-based estimators. In addition, the proposed methods show competitive performance whether the MAR data are accessible (NB) or not (LR) in the propensity estimation. In addition, we provide the results with varying kernel bandwidth in Appendix K.

## 7 CONCLUSION

In this paper, we first formulate the neighborhood effect in RS as an interference problem in causal inference, thereby formulating the neighborhood effect and selection bias in a unified way. Next, a neighborhood treatment representation vector is introduced to reduce the dimension and sparsity of the neighborhood treatments. Based on it, we reformulate the potential feedback and propose a novel ideal loss that can be used to deal with selection bias in the presence of neighborhood effects. Then, we propose two novel kernel-smoothing-based neighborhood estimators for the ideal loss, which allows the neighborhood treatment representation vector to have continuous probability density. We systematically analyze the properties of the proposed estimators, including the bias, variance, optimal bandwidth, and generalization error bound. In addition, we also theoretically establish the connection between the debiasing methods considering and ignoring the neighborhood effect. Extensive experiments are conducted on semi-synthetic and real-world data to demonstrate the effectiveness of our approaches. A limitation of this work is that the hypothesis space  $\mathcal{G}$  of  $\mathbf{g}$  relies on a prior knowledge, and it is not obvious to choose it in practice. We leave it for our future work.

## A RELATED WORK

**Selection Bias.** Selection bias has been widely studied in RS (Wu et al., 2022). For instance, Marlin and Zemel (2009); Steck (2010) discussed the error-imputation-based methods, Schnabel et al. (2016) recommended using the inverse propensity score (IPS) method for unbiased learning, and Saito (2019) extended it to debiasing for implicit feedback. Wang et al. (2019) proposed a doubly robust (DR) joint learning method and achieved superior performance. Subsequently, various novel model structures and algorithms are designed to enhance the base DR method, such as Guo et al. (2021); Dai et al. (2022); Li et al. (2023b;d), which proposed new DR methods by further reducing the bias or variance of the DR estimator, Zhang et al. (2020) proposed multi-task learning through sharing the parameters between the propensity and prediction model, Wang et al. (2021); Chen et al. (2021a); Li et al. (2023c) proposed using a small uniform dataset to enhance the performance of prediction model, and Ding et al. (2022) proposed an adversarial learning-based framework to address the unmeasured confounders. However, a user’s feedback on an item may receive influence from the other user-item pairs (Zheng et al., 2021). To fill this gap, Chen et al. (2021c) focuses on the task of learning to rank (LTR), addressing position bias using implicit feedback data. They consider "other user-item interactions" as "confounders" from a counterfactual perspective, and use embedding as a proxy confounder to capture the influence of "other user-item interactions". Different from Chen et al. (2021c), our paper focuses on the selection bias in the context of rating prediction, and regards "other user-item interactions" as a new "treatment" from the perspective of interference in causal inference. We formulate the influence of "other user-item interactions" as an interference problem in causal inference, and introduce a treatment representation to capture the influence. On this basis, we propose a novel ideal loss that can be used to deal with selection bias in the presence of interference.

**Interference.** Interference is a common problem in observational studies in causal inference, and the effects of interference are also called spillover effects in economics or peer effects in social sciences (Forastiere et al., 2021). Early literature focuses on the case of partial interference (Hong and Raudenbush, 2006; Sobel, 2006; Hudgens and Halloran, 2008; Tchetgen and VanderWeele, 2012; Ferracci et al., 2014), i.e., the sample can be divided into multiple groups, with interference between units in the same group, while units between groups are independent. Recent works have attempted to further relax the partial interference assumption by allowing for a wide variety of interference patterns (Ogburn and VanderWeele, 2014; Aronow and Samii, 2017), such as direct interference (Forastiere et al., 2021), interference by contagion (Ogburn and VanderWeele, 2017), allocational interference (Ogburn and VanderWeele, 2014), or their hybrids (Tchetgen et al., 2021). These studies differ from ours in a number of important ways: (1) their goal is to estimate the main effect and neighborhood effect, while our goal is to achieve unbiased learning of the prediction model that is more challenging and need to carefully design the loss and the training algorithm to mitigate the neighborhood effect; (2) they do not use treatment representation and the estimation does not take into account the possible cases of continuous and multi-dimensional representations while we do.

## B PROOFS OF THEOREMS 1 AND 2

Recall that  $p_{u,i}(\mathbf{g}) = \mathbb{P}(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})$  and  $\hat{r}_{u,i} = f_{\theta}(x_{u,i})$  are functions of  $x_{u,i}$ ,  $\delta_{u,i}(\mathbf{g}) = \delta(\hat{r}_{u,i}, r_{u,i}(1, \mathbf{g}))$ ,  $\mathbb{P}$  and  $\mathbb{E}$  denote the distribution and expectation on the target population  $\mathcal{D}$ , and  $p(\cdot)$  denotes the probability density function of  $\mathbb{P}$ .

**Theorem 1** (Identifiability). *Under Assumptions 1-3,  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g})$  and  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$  are identifiable.*

*Proof of Theorem 1.* Since

$$\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}) = \int \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g})\pi(\mathbf{g})d\mathbf{g},$$

it suffices to show that  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g})$  is identifiable. This follows immediately from the following equations

$$\begin{aligned}
\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g}) &= \mathbb{E}[\delta(\hat{r}_{u,i}, r_{u,i}(1, \mathbf{g}))] \\
&= \mathbb{E}\left[\mathbb{E}\left\{\delta(\hat{r}_{u,i}, r_{u,i}(1, \mathbf{g})) \mid x_{u,i}\right\}\right] \quad (\text{the law of iterated expectations}) \\
&= \mathbb{E}\left[\mathbb{E}\left\{\delta(\hat{r}_{u,i}, r_{u,i}(1, \mathbf{g})) \mid x_{u,i}, o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g}\right\}\right] \quad (\text{Assumption 3}) \\
&= \mathbb{E}\left[\mathbb{E}\left\{\delta(\hat{r}_{u,i}, r_{u,i}) \mid x_{u,i}, o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g}\right\}\right] \quad (\text{Assumption 2}) \\
&= \int \int \delta(\hat{r}_{u,i}, r_{u,i}) p(r_{u,i} | x_{u,i}, o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g}) p(x_{u,i}) dr_{u,i} dx_{u,i}.
\end{aligned}$$

□

**Theorem 2** (Link to selection bias). *Under Assumptions 1-3,*

- (a) if  $\mathbf{g}_{u,i} \perp\!\!\!\perp o_{u,i} \mid x_{u,i}$ ,  $\mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}}) = \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$ .  
(b) if  $\mathbf{g}_{u,i} \not\perp\!\!\!\perp o_{u,i} \mid x_{u,i}$ ,  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}) - \mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}})$  equals

$$\int \mathbb{E}\left[\mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \cdot \left\{p(\mathbf{g}_{u,i} = \mathbf{g} | x_{u,i}) - p(\mathbf{g}_{u,i} = \mathbf{g} | x_{u,i}, o_{u,i} = 1)\right\}\right] \pi(\mathbf{g}) d\mathbf{g}.$$

*Proof of Theorem 2.* For previous methods addressing selection bias without taking into account interference, the ideal loss  $\mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}})$  is

$$\begin{aligned}
\mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}}) &= \mathbb{E}[\delta(\hat{r}_{u,i}, r_{u,i}(1))] \\
&= \mathbb{E}[\mathbb{E}\{\delta(\hat{r}_{u,i}, r_{u,i}(1)) | x_{u,i}\}] \\
&= \mathbb{E}[\mathbb{E}\{\delta(\hat{r}_{u,i}, r_{u,i}) | x_{u,i}, o_{u,i} = 1\}] \\
&= \mathbb{E}\left[\mathbb{E}\left\{\delta(\hat{r}_{u,i}, r_{u,i}) | x_{u,i}, o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g}\right\} \cdot p(\mathbf{g}_{u,i} = \mathbf{g} | x_{u,i}, o_{u,i} = 1)\right] \\
&= \mathbb{E}\left[\mathbb{E}\left\{\delta_{u,i}(\mathbf{g}) | x_{u,i}, o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g}\right\} \cdot p(\mathbf{g}_{u,i} = \mathbf{g} | x_{u,i}, o_{u,i} = 1)\right] \\
&= \mathbb{E}\left[\mathbb{E}\left\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\right\} \cdot p(\mathbf{g}_{u,i} = \mathbf{g} | x_{u,i}, o_{u,i} = 1)\right].
\end{aligned}$$

For the proposed method addressing selection bias under interference, our newly defined ideal loss  $\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$  is

$$\begin{aligned}
\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}) &= \int \mathbb{E}[\delta(\hat{r}_{u,i}, r_{u,i}(1, \mathbf{g}))] \pi(\mathbf{g}) d\mathbf{g} \\
&= \int \mathbb{E}[\mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\}] \pi(\mathbf{g}) d\mathbf{g} \\
&= \int \mathbb{E}\left[\mathbb{E}\left\{\delta_{u,i}(\mathbf{g}) | x_{u,i}, \mathbf{g}_{u,i} = \mathbf{g}\right\} \cdot p(\mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})\right] \pi(\mathbf{g}) d\mathbf{g} \\
&= \int \mathbb{E}\left[\mathbb{E}\left\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\right\} \cdot p(\mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})\right] \pi(\mathbf{g}) d\mathbf{g}.
\end{aligned}$$

Theorem 2(b) follows immediately from these two rewritten equations. When  $\mathbf{g}_{u,i} \perp\!\!\!\perp o_{u,i} \mid x_{u,i}$ , we have  $p(\mathbf{g}_{u,i} = \mathbf{g} | x_{u,i} = x, o_{u,i} = 1) = p(\mathbf{g}_{u,i} = \mathbf{g} | x_{u,i} = x)$ , which leads to  $\mathcal{L}_{\text{ideal}}(\hat{\mathbf{R}}) = \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})$ . This completes the proof of Theorem 2(a).

□

## C PROOF OF THEOREM 3

**Theorem 3** (Bias and Variance of N-IPS and N-DR). *Under Assumptions 1-4,*

(a) the bias of the N-DR estimator is

$$\text{Bias}(\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})) = \frac{1}{2}\mu_2 \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \right] \pi(\mathbf{g}) d\mathbf{g} \cdot h^2 + o(h^2),$$

where  $\mu_2 = \int K(t)t^2 dt$ . The bias of the N-IPS estimator is

$$\text{Bias}(\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})) = \frac{1}{2}\mu_2 \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \cdot \delta_{u,i}(\mathbf{g}) \right] \pi(\mathbf{g}) d\mathbf{g} \cdot h^2 + o(h^2).$$

(b) the variance of the N-DR estimator is

$$\mathbb{V}(\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})) = \frac{1}{|\mathcal{D}|h} \int \psi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g} + o\left(\frac{1}{|\mathcal{D}|h}\right),$$

where

$$\psi(\mathbf{g}) = \int \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \bar{K}\left(\frac{\mathbf{g} - \mathbf{g}'}{h}\right) \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \{\delta_{u,i}(\mathbf{g}') - \hat{\delta}_{u,i}(\mathbf{g}')\} \pi(\mathbf{g}') d\mathbf{g}'$$

is a bounded function of  $\mathbf{g}$ ,  $\bar{K}(\cdot) = \int K(t) K(\cdot + t) dt$ . The variance of the N-IPS estimator is

$$\mathbb{V}(\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})) = \frac{1}{|\mathcal{D}|h} \int \varphi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g} + o\left(\frac{1}{|\mathcal{D}|h}\right).$$

where

$$\varphi(\mathbf{g}) = \int \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \bar{K}\left(\frac{\mathbf{g} - \mathbf{g}'}{h}\right) \cdot \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \pi(\mathbf{g}') d\mathbf{g}'$$

is a bounded function of  $\mathbf{g}$ .

*Proof of Theorem 3. The Bias.* We first show the bias of the N-IPS estimator, and the bias of the N-DR estimator can be shown similarly. For a given  $\mathbf{g}$ ,

$$\begin{aligned} \mathbb{E}[\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}|\mathbf{g})] &= \mathbb{E} \left[ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot p_{u,i}(\mathbf{g})} \right] \\ &= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \mathbb{E} \left\{ o_{u,i} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i} - \mathbf{g}}{h}\right) \middle| x_{u,i} \right\} \cdot \mathbb{E} \{ \delta_{u,i}(\mathbf{g}) | x_{u,i} \} \right] \\ &= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int o_{u,i} \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i} - \mathbf{g}}{h}\right) p(o_{u,i}, \mathbf{g}_{u,i} | x_{u,i}) d o_{u,i} d \mathbf{g}_{u,i} \cdot \mathbb{E} \{ \delta_{u,i}(\mathbf{g}) | x_{u,i} \} \right] \\ &= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i} - \mathbf{g}}{h}\right) p(o_{u,i} = 1, \mathbf{g}_{u,i} | x_{u,i}) d \mathbf{g}_{u,i} \cdot \mathbb{E} \{ \delta_{u,i}(\mathbf{g}) | x_{u,i} \} \right] \end{aligned}$$

where the second equation follows from Assumption 3. Letting  $t = (\mathbf{g}_{u,i} - \mathbf{g})/h$ , we have  $\mathbf{g}_{u,i} = \mathbf{g} + ht$  and  $d\mathbf{g}_{u,i} = hdt$ , and then

$$\begin{aligned}
& \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i} - \mathbf{g}}{h}\right) p(o_{u,i} = 1, \mathbf{g}_{u,i} | x_{u,i}) d\mathbf{g}_{u,i} \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int K(t) p(o_{u,i} = 1, \mathbf{g} + ht | x_{u,i}) dt \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int K(t) \left\{ p(o_{u,i} = 1, \mathbf{g} | x_{u,i}) + \frac{\partial p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}} ht \right. \right. \\
&\quad \left. \left. + \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \frac{h^2 t^2}{2} + o(h^2) \right\} dt \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int K(t) dt \cdot p(o_{u,i} = 1, \mathbf{g} | x_{u,i}) \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] \\
&\quad + \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int K(t) t dt \cdot \frac{\partial p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}} h \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] \\
&\quad + \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int K(t) t^2 dt \cdot \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \frac{h^2}{2} \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] + o(h^2) \\
&= \mathbb{E} [\mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\}] + \frac{1}{2} \mu_2 \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \cdot \delta_{u,i}(\mathbf{g}) \right] h^2 + o(h^2) \\
&= \mathbb{E} [\delta_{u,i}(\mathbf{g})] + \frac{1}{2} \mu_2 \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \cdot \delta_{u,i}(\mathbf{g}) \right] h^2 + o(h^2) \\
&= \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g}) + \frac{1}{2} \mu_2 \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \cdot \delta_{u,i}(\mathbf{g}) \right] h^2 + o(h^2),
\end{aligned}$$

where the third equation is a Taylor expansion of  $p(o_{u,i} = 1, \mathbf{g} + ht | x_{u,i})$  under Assumption 4(a). Thus, the bias of  $\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})$  is

$$\begin{aligned}
& \mathbb{E}[\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})] - \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}) \\
&= \mathbb{E} \left[ \int_{\mathbf{g}} \{ \mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}|\mathbf{g}) - \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g}) \} \pi(\mathbf{g}) d\mathbf{g} \right] \\
&= \int_{\mathbf{g}} \mathbb{E} \{ \mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}|\mathbf{g}) - \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g}) \} \pi(\mathbf{g}) d\mathbf{g} \\
&= \frac{1}{2} \mu_2 \int_{\mathbf{g}} \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \cdot \delta_{u,i}(\mathbf{g}) \right] \pi(\mathbf{g}) d\mathbf{g} \cdot h^2 + o(h^2).
\end{aligned}$$

Likewise, for a given  $\mathbf{g}$  and  $\hat{\delta}_{u,i}(\mathbf{g})$ , by a similar argument of proof of the bias of N-IPS estimator,

$$\begin{aligned}
& \mathbb{E}[\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}|\mathbf{g})] \\
&= \mathbb{E} \left[ \delta_{u,i}(\mathbf{g}) + \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\}}{h \cdot p_{u,i}(\mathbf{g})} \right] \\
&= \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g}) + \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \mathbb{E} \left\{ o_{u,i} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i} - \mathbf{g}}{h}\right) \middle| x_{u,i} \right\} \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g}) | x_{u,i}\} \right] \\
&= \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}|\mathbf{g}) + \frac{1}{2} \mu_2 \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \right] h^2 + o(h^2).
\end{aligned}$$

Thus, the bias of  $\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}})$  is given as

$$\frac{1}{2} \mu_2 \int_{\mathbf{g}} \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \right] \pi(\mathbf{g}) d\mathbf{g} \cdot h^2 + o(h^2).$$

**The Variance.** Next, we calculate the variance of the proposed N-IPS and N-DR estimators. By definition, the variance of  $\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})$  can be represented as

$$\begin{aligned}
& \mathbb{V}\{\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})\} \\
&= \mathbb{V}\left\{\int \mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}|\mathbf{g})\pi(\mathbf{g})d\mathbf{g}\right\} \\
&= \mathbb{V}\left[\frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\pi(\mathbf{g})d\mathbf{g}\right] \\
&= \frac{1}{|\mathcal{D}|} \mathbb{V}\left[\int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\pi(\mathbf{g})d\mathbf{g}\right] \\
&= \frac{1}{|\mathcal{D}|} \left[ \mathbb{E}\left\{\left(\int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\pi(\mathbf{g})d\mathbf{g}\right)^2\right\} \right. \\
&\quad \left. - \left\{\mathbb{E}\left(\int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\pi(\mathbf{g})d\mathbf{g}\right)\right\}^2 \right]. \tag{A.1}
\end{aligned}$$

According to the above result of the bias of the N-IPS estimator,

$$\begin{aligned}
& \left\{\mathbb{E}\left(\int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\pi(\mathbf{g})d\mathbf{g}\right)\right\}^2 \\
&= \left\{\mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}) + \frac{1}{2}\mu_2 \int \mathbb{E}\left[\frac{\partial^2 p(o_{u,i}=1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \cdot \delta_{u,i}(\mathbf{g})\right]\pi(\mathbf{g})d\mathbf{g} \cdot h^2 + o(h^2)\right\}^2 \\
&= [\mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}})]^2 + O(h^2). \tag{A.2}
\end{aligned}$$

Then, we focus on analyzing the term  $\mathbb{E}\left\{\left(\int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\pi(\mathbf{g})d\mathbf{g}\right)^2\right\}$ . Observe that

$$\begin{aligned}
& \left(\int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\pi(\mathbf{g})d\mathbf{g}\right)^2 \\
&= \left(\int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\pi(\mathbf{g})d\mathbf{g}\right) \\
&\quad \cdot \left(\int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g}')} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}'}{h}\right) \cdot \delta_{u,i}(\mathbf{g}')\pi(\mathbf{g}')d\mathbf{g}'\right) \\
&= \int \int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})p_{u,i}(\mathbf{g}')} \cdot \frac{1}{h^2} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}'}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}')\pi(\mathbf{g})\pi(\mathbf{g}')d\mathbf{g}d\mathbf{g}'
\end{aligned}$$

Swap the order of integration and expectation leads to that

$$\begin{aligned}
& \mathbb{E}\left\{\left(\int \frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})} \cdot \frac{1}{h} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\pi(\mathbf{g})d\mathbf{g}\right)^2\right\} \\
&= \int \int \mathbb{E}\left[\frac{\mathbb{I}(o_{u,i}=1)}{p_{u,i}(\mathbf{g})p_{u,i}(\mathbf{g}')} \cdot \frac{1}{h^2} K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}}{h}\right) K\left(\frac{\mathbf{g}_{u,i}-\mathbf{g}'}{h}\right) \cdot \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}')\right]\pi(\mathbf{g})\pi(\mathbf{g}')d\mathbf{g}d\mathbf{g}'.
\end{aligned}$$

Let  $\mathbf{g}_{u,i} = \mathbf{g} + ht$ , then  $\mathbf{g}_{u,i} - \mathbf{g}' = (\mathbf{g} - \mathbf{g}') + ht$ , it follows that

$$\begin{aligned}
& \mathbb{E} \left[ \frac{\mathbb{I}(o_{u,i} = 1)}{p_{u,i}(\mathbf{g})p_{u,i}(\mathbf{g}')} \cdot \frac{1}{h^2} K \left( \frac{\mathbf{g}_{u,i} - \mathbf{g}}{h} \right) K \left( \frac{\mathbf{g}_{u,i} - \mathbf{g}'}{h} \right) \cdot \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}') \right] \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})p_{u,i}(\mathbf{g}')} \cdot \mathbb{E} \left\{ \mathbb{I}(o_{u,i} = 1) \frac{1}{h^2} K \left( \frac{\mathbf{g}_{u,i} - \mathbf{g}}{h} \right) K \left( \frac{\mathbf{g}_{u,i} - \mathbf{g}'}{h} \right) \middle| x_{u,i} \right\} \cdot \mathbb{E} \left\{ \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}') \middle| x_{u,i} \right\} \right] \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})p_{u,i}(\mathbf{g}')} \cdot \int \left\{ \frac{1}{h} K(t) K \left( \frac{\mathbf{g} - \mathbf{g}'}{h} + t \right) p(o_{u,i} = 1, \mathbf{g} + ht | x_{u,i}) \right\} dt \cdot \mathbb{E} \left\{ \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}') \middle| x_{u,i} \right\} \right] \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})p_{u,i}(\mathbf{g}')} \cdot \int \left\{ \frac{1}{h} K(t) K \left( \frac{\mathbf{g} - \mathbf{g}'}{h} + t \right) p(o_{u,i} = 1, \mathbf{g} | x_{u,i}) + O(h)t \right\} dt \cdot \mathbb{E} \left\{ \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}') \middle| x_{u,i} \right\} \right] \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \int \frac{1}{h} K(t) K \left( \frac{\mathbf{g} - \mathbf{g}'}{h} + t \right) dt \cdot \mathbb{E} \left\{ \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}') \middle| x_{u,i} \right\} \right] \cdot \{1 + O(h)\} \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \int \frac{1}{h} K(t) K \left( \frac{\mathbf{g} - \mathbf{g}'}{h} + t \right) dt \cdot \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}') \right] \cdot \{1 + O(h)\}.
\end{aligned}$$

Denote  $\int K(t) K \left( \frac{\mathbf{g} - \mathbf{g}'}{h} + t \right) dt = \bar{K} \left( \frac{\mathbf{g} - \mathbf{g}'}{h} \right)$ , then

$$\begin{aligned}
& \mathbb{E} \left\{ \left( \int \frac{\mathbb{I}(o_{u,i} = 1)}{p_{u,i}(\mathbf{g})} \cdot \frac{1}{h} K \left( \frac{\mathbf{g}_{u,i} - \mathbf{g}}{h} \right) \cdot \delta_{u,i}(\mathbf{g})\pi(\mathbf{g})d\mathbf{g} \right)^2 \right\} \\
&= \int \int \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g}')}\cdot \frac{1}{h} \bar{K} \left( \frac{\mathbf{g} - \mathbf{g}'}{h} \right) \cdot \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}') \right] \cdot \{1 + O(h)\} \cdot \pi(\mathbf{g})\pi(\mathbf{g}')d\mathbf{g}d\mathbf{g}' \\
&= \int \mathbb{E} \left[ \int \frac{1}{p_{u,i}(\mathbf{g}')}\cdot \frac{1}{h} \bar{K} \left( \frac{\mathbf{g} - \mathbf{g}'}{h} \right) \cdot \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}')\pi(\mathbf{g}')d\mathbf{g}' \right] \cdot \{1 + O(h)\} \cdot \pi(\mathbf{g})d\mathbf{g} \\
&\triangleq \int \varphi(\mathbf{g})\pi(\mathbf{g})d\mathbf{g} \frac{1}{h} + O(1), \tag{A.3}
\end{aligned}$$

where

$$\varphi(\mathbf{g}) = \int \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \bar{K} \left( \frac{\mathbf{g} - \mathbf{g}'}{h} \right) \cdot \delta_{u,i}(\mathbf{g})\delta_{u,i}(\mathbf{g}')\pi(\mathbf{g}')d\mathbf{g}'$$

is a bounded function of  $\mathbf{g}$ .

Combing equations (A.1), (A.2), and (A.3) gives that

$$\begin{aligned}
\mathbb{V}\{\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})\} &= \frac{1}{|\mathcal{D}|} \left[ \int \varphi(\mathbf{g})\pi(\mathbf{g})d\mathbf{g} \frac{1}{h} + O(1) - [\mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}})]^2 + O(h^2) \right] \\
&= \frac{1}{|\mathcal{D}|h} \int \varphi(\mathbf{g})\pi(\mathbf{g})d\mathbf{g} + o\left(\frac{1}{|\mathcal{D}|h}\right).
\end{aligned}$$

Similarly, the variance of the N-DR estimator is given by

$$\mathbb{V}(\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})) = \frac{1}{|\mathcal{D}|h} \int \psi(\mathbf{g})\pi(\mathbf{g})d\mathbf{g} + o\left(\frac{1}{|\mathcal{D}|h}\right),$$

where

$$\psi(\mathbf{g}) = \int \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \bar{K} \left( \frac{\mathbf{g} - \mathbf{g}'}{h} \right) \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\}\{\delta_{u,i}(\mathbf{g}') - \hat{\delta}_{u,i}(\mathbf{g}')\}\pi(\mathbf{g}')d\mathbf{g}'$$

is a bounded function of  $\mathbf{g}$ .

□

## D PROOF OF THEOREM 4

**Theorem 4** (Optimal bandwidth of N-IPS and N-DR). *Under Assumptions 1–4,*

(a) the optimal bandwidth for the N-IPS estimator in terms of the asymptotic mean-squared error is

$$h_{\text{N-IPS}}^* = \left[ \frac{\int \varphi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g}}{4|\mathcal{D}| \left( \frac{1}{2} \mu_2 \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i}=1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \cdot \delta_{u,i}(\mathbf{g}) \right] \pi(\mathbf{g}) d\mathbf{g} \right)^2} \right]^{1/5},$$

where  $\varphi(\mathbf{g})$  is defined in Theorem 3.

(b) the optimal bandwidth for the N-DR estimator in terms of the asymptotic mean-squared error is

$$h_{\text{N-DR}}^* = \left[ \frac{\int \psi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g}}{4|\mathcal{D}| \left( \frac{1}{2} \mu_2 \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i}=1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \right] \pi(\mathbf{g}) d\mathbf{g} \right)^2} \right]^{1/5},$$

where  $\psi(\mathbf{g})$  is defined in Theorem 3.

*Proof of Theorem 4.* Recall that

$$\begin{aligned} \text{Bias}[\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})] &= \frac{1}{2} \mu_2 \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i}=1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \cdot \delta_{u,i}(\mathbf{g}) \right] \pi(\mathbf{g}) d\mathbf{g} \cdot h^2 + o(h^2), \\ \text{Var}[\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})] &= \frac{1}{|\mathcal{D}|h} \int \varphi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g} + o\left(\frac{1}{|\mathcal{D}|h}\right). \end{aligned}$$

The MSE of the N-IPS estimator is given as

$$\begin{aligned} &\mathbb{E}[(\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}) - \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}))^2] \\ &= (\text{Bias})^2 + \text{Variance} \\ &= \left( \frac{1}{2} \mu_2 \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i}=1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \cdot \delta_{u,i}(\mathbf{g}) \right] \pi(\mathbf{g}) d\mathbf{g} \right)^2 \cdot h^4 + o(h^4) \\ &\quad + \frac{1}{|\mathcal{D}|h} \int \varphi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g} + o\left(\frac{1}{|\mathcal{D}|h}\right). \end{aligned}$$

Minimizing the leading terms of the above MSE with respect to  $h$  leads to that

$$h_{\text{N-IPS}}^* = \left[ \frac{\int \varphi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g}}{4|\mathcal{D}| \left( \frac{1}{2} \mu_2 \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i}=1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \cdot \delta_{u,i}(\mathbf{g}) \right] \pi(\mathbf{g}) d\mathbf{g} \right)^2} \right]^{1/5} = O(|\mathcal{D}|^{-1/5}).$$

Similarly, the optimal bandwidth for the N-DR estimator in terms of the asymptotic mean-squared error can be obtained.  $\square$

## E PROOF OF THEOREM 5

**Lemma 1** (McDiarmid's inequality). *Let  $X_1, \dots, X_m \in \mathcal{X}^m$  be a set of  $m \geq 1$  independent random variables and assume that there exist  $c_1, \dots, c_m > 0$  such that  $f : \mathcal{X}^m \rightarrow \mathbb{R}$  satisfies the following conditions:*

$$|f(x_1, \dots, x_i, \dots, x_m) - f(x_1, \dots, x'_i, \dots, x_m)| \leq c_i,$$

*for all  $i \in \{1, 2, \dots, m\}$  and any points  $x_1, \dots, x_m, x'_i \in \mathcal{X}$ . Let  $f(S)$  denote  $f(X_1, \dots, X_m)$ , then for all  $\epsilon > 0$ , the following inequalities hold:*

$$\begin{aligned} \mathbb{P}[f(S) - \mathbb{E}\{f(S)\} \geq \epsilon] &\leq \exp\left(-\frac{2\epsilon^2}{\sum_{i=1}^m c_i^2}\right) \\ \mathbb{P}[f(S) - \mathbb{E}\{f(S)\} \leq -\epsilon] &\leq \exp\left(-\frac{2\epsilon^2}{\sum_{i=1}^m c_i^2}\right). \end{aligned}$$

*Proof.* The proof can be found in Appendix D.3 of (Mohri et al., 2018).  $\square$

**Lemma 2.** *Under the conditions in Lemma 1, we have with probability at least  $1 - \eta$ ,*

$$|f(S) - \mathbb{E}[f(S)]| \leq \sqrt{\frac{\sum_{i=1}^m c_i^2}{2} \log\left(\frac{2}{\eta}\right)}.$$

*In particular, if  $c_i \leq c$  for all  $i \in \{1, 2, \dots, m\}$ ,*

$$|f(S) - \mathbb{E}[f(S)]| \leq c \sqrt{\frac{m}{2} \log\left(\frac{2}{\eta}\right)}.$$

*Proof.* This conclusion follows immediately by letting  $\eta = 2 \exp\left(-\frac{2\epsilon^2}{\sum_{i=1}^m c_i^2}\right)$  in Lemma 1.  $\square$

**Lemma 3** (Rademacher comparison lemma). *Let  $X \in \mathcal{X}$  be a random variable with distribution  $\mathbb{P}$ ,  $X_1, \dots, X_m$  be a set of independent copies of  $X$ ,  $\mathcal{F}$  be a class of real-valued functions on  $\mathcal{X}$ . Then we have*

$$\mathbb{E} \sup_{f \in \mathcal{G}} \left| \frac{1}{m} \sum_{i=1}^m f(X_i) - \mathbb{E}(f(X_i)) \right| \leq 2 \mathbb{E} \left[ \mathbb{E}_{\sigma \sim \{-1, +1\}^m} \sup_{f \in \mathcal{G}} \frac{1}{m} \sum_{i=1}^m f(X_i) \sigma_i \right],$$

*where  $\sigma = (\sigma_1, \dots, \sigma_m)$  is a Rademacher sequence.*

*Proof.* The proof can be found in Lemma 26.2 of (Shalev-Shwartz and Ben-David, 2014).  $\square$

Recall that  $\mathcal{F}$  is the hypothesis space of prediction matrices  $\hat{\mathbf{R}}$  (or prediction model  $f_\theta$ ), the Rademacher complexity is

$$\mathcal{R}(\mathcal{F}) = \mathbb{E}_{\sigma \sim \{-1, +1\}^{|\mathcal{D}|}} \sup_{f_\theta \in \mathcal{F}} \left[ \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \sigma_{u,i} \delta_{u,i}(\mathbf{g}) \right].$$

**Theorem 5** (Uniform Tail Bound of N-IPS and N-DR). *Under Assumptions 1–5 and suppose that  $K(t) \leq M_K$ , then for all  $\hat{\mathbf{R}} \in \mathcal{F}$ , we have with probability at least  $1 - \eta$ ,*

(a)

$$\sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}) - \mathbb{E}[\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})] \right| \leq \frac{2M_p M_K}{h} \mathcal{R}(\mathcal{F}) + \frac{5}{2} \frac{M_p M_K M_\delta}{h} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)},$$

(b)

$$\sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}) - \mathbb{E}[\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})] \right| \leq \frac{2M_p M_K}{h} \mathcal{R}(\mathcal{F}) + \frac{5}{2} \frac{M_p M_K M_{|\delta-\hat{\delta}|}}{h} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)}.$$

*Proof of Theorem 5.* We first discuss the uniform tail bound of  $\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})$ , that is, we want to show the upper bound of  $\sup_{\hat{\mathbf{R}} \in \mathcal{F}} |\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}) - \mathbb{E}\{\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})\}|$ .

Note that

$$\begin{aligned} & \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}) - \mathbb{E}\{\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})\} \right| \\ &= \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \int \pi(\mathbf{g}) \left[ \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right. \right. \\ & \quad \left. \left. - \mathbb{E} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right] d\mathbf{g} \right| \\ &\leq \int \pi(\mathbf{g}) \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right. \\ & \quad \left. - \mathbb{E} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right| d\mathbf{g} \end{aligned}$$

For all prediction model  $\hat{\mathbf{R}} \in \mathcal{F}$  and  $\mathbf{g}$ , we have

$$\frac{1}{|\mathcal{D}|} \left| \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} - \frac{\mathbb{I}(o_{u',i'} = 1) \cdot K((\mathbf{g}_{u',i'} - \mathbf{g})/h) \cdot \delta_{u',i'}(\mathbf{g})}{h \cdot \hat{p}_{u',i'}(\mathbf{g})} \right| \leq \frac{M_p M_\delta M_K}{h|\mathcal{D}|},$$

then applying Lemma 2 yields that with probability at least  $1 - \eta/2$

$$\begin{aligned} & \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathbb{E} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right. \\ & \quad \left. - \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right| \\ & \leq \mathbb{E} \left[ \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathbb{E} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right. \right. \\ & \quad \left. \left. - \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right| \right] + \frac{M_p M_\delta M_K}{2h} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)} \\ & \leq \frac{M_p M_K}{h} 2\mathbb{E}[\mathcal{R}(\mathcal{F})] + \frac{M_p M_\delta M_K}{2h} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)}, \end{aligned} \quad (\text{A.4})$$

where the last inequality holds by Lemma 3 and

$$\frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h)}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \leq \frac{M_p M_K}{h}.$$

Recall that

$$\mathcal{R}(\mathcal{F}) = \mathbb{E}_{\boldsymbol{\sigma} \sim \{-1, +1\}^{|\mathcal{D}|}} \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left[ \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \sigma_{u,i} \delta_{u,i}(\mathbf{g}) \right]$$

and let  $f(S) = \mathcal{R}(\mathcal{F})$  and  $c = 2M_\delta/|\mathcal{D}|$  in Lemmas 1 and 2, by applying Lemma 2 again, we have with probability at least  $1 - \eta/2$

$$\mathbb{E}[\mathcal{R}(\mathcal{F})] - \mathcal{R}(\mathcal{F}) \leq M_\delta \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)}. \quad (\text{A.5})$$

Combining inequalities (A.4) and (A.5) leads to that with probability at least  $1 - \eta$

$$\begin{aligned} & \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right. \\ & \quad \left. - \mathbb{E} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \delta_{u,i}(\mathbf{g})}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right| \\ & \leq \frac{2M_p M_K}{h} \mathcal{R}(\mathcal{F}) + \frac{5}{2} \frac{M_p M_K M_\delta}{h} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)}, \end{aligned}$$

which implies that the conclusion (a) by noting that  $\int \pi(\mathbf{g}) d\mathbf{g} = 1$

Next, we show the uniform tail bound of  $\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}})$ . Note that

$$\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}) = \delta_{u,i}(\mathbf{g}) + \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\}}{h \cdot \hat{p}_{u,i}(\mathbf{g})}$$

and

$$\begin{aligned} & \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}) - \mathbb{E}\{\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})\} \right| \\ &= \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \int \pi(\mathbf{g}) \left[ \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\}}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right. \\ & \quad \left. - \mathbb{E} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/h) \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\}}{h \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right] d\mathbf{g}, \end{aligned}$$

which has the same form as  $\sup_{\hat{\mathbf{R}} \in \mathcal{F}} |\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}) - \mathbb{E}\{\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})\}|$ , except that  $\delta_{u,i}(\mathbf{g})$  is replaced by  $\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}$ . Then by a similar argument of the proof of the N-IPS estimator, we obtain the conclusion (b).  $\square$

## F PROOF OF COROLLARY 6

Let

$$\hat{\mathbf{R}}^\dagger = \arg \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}), \quad \hat{\mathbf{R}}^\ddagger = \arg \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}).$$

The following Corollary 6 shows the generalization bounds of the N-IPS and N-DR estimators.

**Corollary 6.** (*Generalization Bound of N-IPS and N-DR*) Under the conditions in Theorem 5, we have with probability at least  $1 - \eta$ ,

(a)

$$\begin{aligned} \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^\dagger) &\leq \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}) + \mu_2 M_{|\delta - \hat{\delta}|} \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \right] \pi(\mathbf{g}) d\mathbf{g} \cdot h^2 + o(h^2) \\ &\quad + \frac{4M_p M_K}{h} \mathcal{R}(\mathcal{F}) + \frac{5M_p M_K M_{|\delta - \hat{\delta}|}}{h} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)}, \end{aligned}$$

(b)

$$\begin{aligned} \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^\ddagger) &\leq \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}) + \mu_2 M_\delta \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial \mathbf{g}^2} \right] \pi(\mathbf{g}) d\mathbf{g} \cdot h^2 + o(h^2) \\ &\quad + \frac{4M_p M_K}{h} \mathcal{R}(\mathcal{F}) + \frac{5M_p M_K M_\delta}{h} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)}, \end{aligned}$$

*Proof.* It suffices to show conclusion (a), since conclusion (b) can be derived from a similar argument. Define

$$\hat{\mathbf{R}}^* = \arg \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}).$$

$$\begin{aligned} & \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^\dagger) - \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}) \\ &= \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^\dagger) - \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^*) \\ &\leq \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^\dagger) - \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}^\dagger) + \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}^\dagger) - \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}^*) + \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}^*) - \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^*) \\ &\leq \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^\dagger) - \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}^\dagger) + \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}^*) - \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^*) \\ &:= A + B, \end{aligned}$$

where

$$\begin{aligned} A &= \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^\dagger) - \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}^\dagger), \\ B &= \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}^*) - \mathcal{L}_{\text{ideal}}^{\text{N}}(\hat{\mathbf{R}}^*). \end{aligned}$$

The term  $A$  can be decomposed as follows

$$\begin{aligned}
A &= \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}^\dagger) - \mathbb{E}[\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}^\dagger)] + \mathbb{E}[\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}^\dagger)] - \mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}^\dagger) \\
&= \left| \text{Bias}[\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}^\dagger)] \right| + \mathbb{E}[\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}^\dagger)] - \mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}^\dagger) \\
&\leq \left| \text{Bias}[\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}^\dagger)] \right| + \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left[ \mathbb{E}\{\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})\} - \mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}) \right] \\
&= \frac{1}{2}\mu_2 \left| \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \right] \pi(\mathbf{g}) d\mathbf{g} \right| \cdot h^2 + o(h^2) \\
&\quad + \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left[ \mathbb{E}\{\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})\} - \mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}) \right] \\
&\leq \frac{1}{2}\mu_2 M_{|\delta - \hat{\delta}|} \left| \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \right] \pi(\mathbf{g}) d\mathbf{g} \right| \cdot h^2 + o(h^2) \\
&\quad + \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left[ \mathbb{E}\{\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})\} - \mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}) \right],
\end{aligned}$$

the upper bound does not depend on  $\hat{\mathbf{R}}^\dagger$ . Likewise, the term  $B$  has the same upper bound of  $A$ , i.e.,

$$\begin{aligned}
B &\leq \frac{1}{2}\mu_2 M_{|\delta - \hat{\delta}|} \left| \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \right] \pi(\mathbf{g}) d\mathbf{g} \right| \cdot h^2 + o(h^2) \\
&\quad + \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left[ \mathbb{E}\{\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})\} - \mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}) \right]
\end{aligned}$$

Then by Theorem 5, we have with probability at least  $1 - \eta$ ,

$$\begin{aligned}
A + B &\leq \mu_2 M_{|\delta - \hat{\delta}|} \left| \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \right] \pi(\mathbf{g}) d\mathbf{g} \right| \cdot h^2 + o(h^2) \\
&\quad + 2 \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left[ \mathbb{E}\{\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})\} - \mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}) \right] \\
&\leq \mu_2 M_{|\delta - \hat{\delta}|} \left| \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}|x_{u,i})}{\partial \mathbf{g}^2} \right] \pi(\mathbf{g}) d\mathbf{g} \right| \cdot h^2 + o(h^2) \\
&\quad + \frac{4M_p M_K}{h} \mathcal{R}(\mathcal{F}) + 5 \frac{M_p M_K M_{|\delta - \hat{\delta}|}}{h} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)},
\end{aligned}$$

which implies the conclusion (a).  $\square$

## G EXTENSION: MULTI-DIMENSIONAL TREATMENT REPRESENTATION

For ease of presentation, we focus on the case of univariate  $\mathbf{g}$  in the manuscript. In this section, we extend the univariate case and consider the case of multi-dimensional  $\mathbf{g}$ .

Suppose that  $\mathbf{g}$  is a  $q$ -dimensional vector denoted as  $\mathbf{g} = (g_1, \dots, g_q)$ . In this case, the bandwidth  $\mathbf{h} = (h_1, \dots, h_q)$  and the kernel function  $\mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) = \prod_{s=1}^q K((g_{u,i}^s - g_s)/h_s)$ , where  $\mathbf{g}_{u,i} = (g_{u,i}^1, \dots, g_{u,i}^q)$  with  $g_{u,i}^s$  being its  $s$ -th element,  $K(\cdot)$  is the univariate kernel function such as Epanechnikov kernel  $K(t) = \frac{3}{4}(1 - t^2)\mathbb{I}\{|t| \leq 1\}$  and Gaussian kernel  $K(t) = \frac{1}{\sqrt{2\pi}} \cdot \exp\{-\frac{t^2}{2}\}$  for  $t \in \mathbb{R}$ . The N-IPS and N-DR estimators are given as

$$\begin{aligned}
\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}) &= \int \mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}|\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g}, \\
\mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}) &= \int \mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}|\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g},
\end{aligned}$$

where

$$\begin{aligned}\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}|\mathbf{g}) &= \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot p_{u,i}(\mathbf{g})}, \\ \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}|\mathbf{g}) &= \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left[ \hat{\delta}_{u,i}(\mathbf{g}) + \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\}}{\prod_{s=1}^q h_s \cdot p_{u,i}(\mathbf{g})} \right].\end{aligned}$$

We show the theoretical properties of the proposed N-IPS and N-DR estimators, extending the results of Theorem 3, Theorem 4, Theorem 5, and Proposition 1. First, we present the bias of the N-IPS and N-DR estimators in the setting of multi-dimension treatment representation.

**Assumption 6 (Regularity conditions for kernel smoothing with multi-dimensional treatment representation)** (a) For  $s = 1, \dots, q$ ,  $h_s \rightarrow 0$  as  $|\mathcal{D}| \rightarrow \infty$ ; (b)  $|\mathcal{D}| \prod_{s=1}^q h_s \rightarrow \infty$  as  $|\mathcal{D}| \rightarrow \infty$ ; (c)  $p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})$  is twice differentiable with respect to  $\mathbf{g} = (g_1, \dots, g_q)$ .

**Theorem 7** (Bias of N-IPS and N-DR Estimators with Multi-dimensional Treatment Representation). *Under Assumptions 1–3 and 6,*

(a) *the bias of the N-IPS estimator is given as*

$$\frac{1}{2} \mu_2 \left[ \sum_{s=1}^q h_s^2 \int \mathbb{E} \left\{ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})}{\partial g_s^2} \cdot \delta_{u,i}(\mathbf{g}) \right\} \pi(\mathbf{g}) d\mathbf{g} \right] + o\left(\sum_{s=1}^q h_s^2\right),$$

where  $\mu_2 = \int K(t)t^2 dt$ . *The bias of the N-DR estimator is given as*

$$\frac{1}{2} \mu_2 \left[ \sum_{s=1}^q h_s^2 \int \mathbb{E} \left\{ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})}{\partial g_s^2} \cdot (\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})) \right\} \pi(\mathbf{g}) d\mathbf{g} \right] + o\left(\sum_{s=1}^q h_s^2\right).$$

(b) *The variance of the N-IPS estimator is*

$$\mathbb{V}(\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})) = \frac{1}{|\mathcal{D}| \prod_{s=1}^q h_s} \int \varphi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g} + o\left(\frac{1}{|\mathcal{D}| \prod_{s=1}^q h_s}\right).$$

where

$$\varphi(\mathbf{g}) = \int \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \bar{K}\left(\frac{\mathbf{g} - \mathbf{g}'}{h}\right) \cdot \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \pi(\mathbf{g}') d\mathbf{g}'$$

is a bounded function of  $\mathbf{g}$ ,  $\bar{K}\left(\frac{\mathbf{g} - \mathbf{g}'}{h}\right) = \int \prod_{s=1}^q K(t_s) K\left(\frac{g_s - g'_s}{h_s} + t_s\right) dt_1 \cdots dt_q$ . *The variance of the N-DR estimator is*

$$\mathbb{V}(\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})) = \frac{1}{|\mathcal{D}| \prod_{s=1}^q h_s} \int \psi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g} + o\left(\frac{1}{|\mathcal{D}| \prod_{s=1}^q h_s}\right),$$

where

$$\psi(\mathbf{g}) = \int \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \bar{K}\left(\frac{\mathbf{g} - \mathbf{g}'}{h}\right) \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \{\delta_{u,i}(\mathbf{g}') - \hat{\delta}_{u,i}(\mathbf{g}')\} \pi(\mathbf{g}') d\mathbf{g}'$$

is a bounded function of  $\mathbf{g}$ .

*Proof of Theorem 6.* We show the bias and variance of the N-IPS estimator, and the bias and variance of the N-DR estimator can be obtained similarly.

**The Bias.** For a given  $\mathbf{g}$ , by a similar argument of the proof of Theorem 3(a),

$$\begin{aligned}\mathbb{E}[\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}|\mathbf{g})] &= \mathbb{E} \left[ \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot p_{u,i}(\mathbf{g})} \right] \\ &= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int \prod_{s=1}^q \frac{1}{h_s} K\left(\frac{g_{u,i}^s - g_s}{h_s}\right) p(o_{u,i} = 1, \mathbf{g}_{u,i} | x_{u,i}) d\mathbf{g}_{u,i} \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right]\end{aligned}$$

Let  $t_s = (g_{u,i}^s - g_s)/h_s$  for  $s = 1, \dots, q$ , then  $g_{u,i}^s = g_s + h_s t_s$ ,  $d\mathbf{g}_{u,i} = dg_{u,i}^1 \cdots dg_{u,i}^q = \prod_{s=1}^q h_s dt_1 \cdots dt_q$ . By a Taylor expansion of  $p(o_{u,i} = 1, g_1 + h_1 t_1, \dots, g_q + h_q t_q | x_{u,i})$ , we have

$$\begin{aligned}
& \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int \prod_{s=1}^q \frac{1}{h_s} K\left(\frac{g_{u,i}^s - g_s}{h_s}\right) p(o_{u,i} = 1, \mathbf{g}_{u,i} | x_{u,i}) d\mathbf{g}_{u,i} \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int \cdots \int \prod_{s=1}^q K(t_s) p(o_{u,i} = 1, g_1 + h_1 t_1, \dots, g_q + h_q t_q | x_{u,i}) dt_1 \cdots dt_q \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \int \cdots \int \prod_{s=1}^q K(t_s) \left\{ p(o_{u,i} = 1, \mathbf{g} | x_{u,i}) + \sum_{s=1}^q \frac{\partial p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial g_s} h_s t_s \right. \right. \\
&\quad \left. \left. + \sum_{s=1}^q \sum_{s'=1}^q \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial g_s \partial g_{s'}} \frac{h_s h_{s'} t_s t_{s'}}{2} + o\left(\sum_{s=1}^q h_s^2\right) \right\} dt_1 \cdots dt_q \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] \\
&= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \cdot \prod_{s=1}^q \int K(t_s) dt_s \cdot p(o_{u,i} = 1, \mathbf{g} | x_{u,i}) \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] + 0 \\
&\quad + \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g})} \sum_{s=1}^q \int K(t_s) t_s^2 dt_s \cdot \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial g_s^2} \frac{h_s^2}{2} \cdot \mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\} \right] + o\left(\sum_{s=1}^q h_s^2\right) \\
&= \mathbb{E}[\mathbb{E}\{\delta_{u,i}(\mathbf{g}) | x_{u,i}\}] + \frac{1}{2} \mu_2 \mathbb{E} \left[ \sum_{s=1}^q \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial g_s^2} \cdot h_s^2 \cdot \delta_{u,i}(\mathbf{g}) \right] + o\left(\sum_{s=1}^q h_s^2\right) \\
&= \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}} | \mathbf{g}) + \frac{1}{2} \mu_2 \mathbb{E} \left[ \sum_{s=1}^q \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial g_s^2} \cdot h_s^2 \cdot \delta_{u,i}(\mathbf{g}) \right] + o\left(\sum_{s=1}^q h_s^2\right).
\end{aligned}$$

Thus, the bias of  $\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})$  is

$$\begin{aligned}
\mathbb{E}[\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})] - \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}) &= \int_{\mathbf{g}} \mathbb{E}\{\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}} | \mathbf{g}) - \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}} | \mathbf{g})\} \pi(\mathbf{g}) d\mathbf{g} \\
&= \frac{1}{2} \mu_2 \left[ \sum_{s=1}^q h_s^2 \int \mathbb{E}\left\{ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g} | x_{u,i})}{\partial g_s^2} \cdot \delta_{u,i}(\mathbf{g}) \right\} \pi(\mathbf{g}) d\mathbf{g} \right] + o\left(\sum_{s=1}^q h_s^2\right),
\end{aligned}$$

**The Variance.** The variance of  $\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})$  can be represented as

$$\begin{aligned}
\mathbb{V}\{\mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}})\} &= \frac{1}{|\mathcal{D}|} \mathbb{V} \left[ \int \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot p_{u,i}(\mathbf{g})} \pi(\mathbf{g}) d\mathbf{g} \right] \\
&= \frac{1}{|\mathcal{D}|} \left[ \mathbb{E} \left\{ \left( \int \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot p_{u,i}(\mathbf{g})} \pi(\mathbf{g}) d\mathbf{g} \right)^2 \right\} \right. \\
&\quad \left. - \left\{ \mathbb{E} \left( \int \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot p_{u,i}(\mathbf{g})} \pi(\mathbf{g}) d\mathbf{g} \right) \right\}^2 \right].
\end{aligned}$$

By the bias of the N-IPS estimator,

$$\left\{ \mathbb{E} \left( \int \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot p_{u,i}(\mathbf{g})} \pi(\mathbf{g}) d\mathbf{g} \right) \right\}^2 = [\mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}})]^2 + O\left(\sum_{s=1}^q h_s^2\right) = O(1).$$

On the other hand, note that

$$\begin{aligned}
& \left( \int \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot p_{u,i}(\mathbf{g})} \pi(\mathbf{g}) d\mathbf{g} \right)^2 \\
&= \int \int \frac{\mathbb{I}(o_{u,i} = 1)}{p_{u,i}(\mathbf{g}) p_{u,i}(\mathbf{g}')} \cdot \frac{1}{\prod_{s=1}^q h_s^2} \mathbf{K}\left(\frac{\mathbf{g}_{u,i} - \mathbf{g}}{\mathbf{h}}\right) \mathbf{K}\left(\frac{\mathbf{g}_{u,i} - \mathbf{g}'}{\mathbf{h}}\right) \cdot \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \pi(\mathbf{g}) \pi(\mathbf{g}') d\mathbf{g} d\mathbf{g}'
\end{aligned}$$

Swap the order of integration and expectation leads to that

$$\begin{aligned} & \mathbb{E} \left\{ \left( \int \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot p_{u,i}(\mathbf{g})} \pi(\mathbf{g}) d\mathbf{g} \right)^2 \right\} \\ &= \int \int \mathbb{E} \left[ \frac{\mathbb{I}(o_{u,i} = 1)}{p_{u,i}(\mathbf{g}) p_{u,i}(\mathbf{g}')} \cdot \frac{1}{\prod_{s=1}^q h_s^2} \mathbf{K} \left( \frac{\mathbf{g}_{u,i} - \mathbf{g}}{\mathbf{h}} \right) \mathbf{K} \left( \frac{\mathbf{g}_{u,i} - \mathbf{g}'}{\mathbf{h}} \right) \cdot \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \right] \pi(\mathbf{g}) \pi(\mathbf{g}') d\mathbf{g} d\mathbf{g}'. \end{aligned}$$

Let  $\mathbf{g}_{u,i} = \mathbf{g} + \mathbf{h}\mathbf{t}$ , i.e.,  $\mathbf{g}_{u,i}^s = g_s + h_s t_s$ , then  $\mathbf{g}_{u,i} - \mathbf{g}' = (\mathbf{g} - \mathbf{g}') + \mathbf{h}\mathbf{t}$ , we have

$$\begin{aligned} & \mathbb{E} \left[ \frac{\mathbb{I}(o_{u,i} = 1)}{p_{u,i}(\mathbf{g}) p_{u,i}(\mathbf{g}')} \cdot \frac{1}{\prod_{s=1}^q h_s^2} \mathbf{K} \left( \frac{\mathbf{g}_{u,i} - \mathbf{g}}{\mathbf{h}} \right) \mathbf{K} \left( \frac{\mathbf{g}_{u,i} - \mathbf{g}'}{\mathbf{h}} \right) \cdot \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \right] \\ &= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g}) p_{u,i}(\mathbf{g}')} \cdot \int \left\{ \prod_{s=1}^q \frac{1}{h_s^2} K(t_s) K \left( \frac{g_s - g'_s}{h_s} + t_s \right) p(o_{u,i} = 1, \mathbf{g} + \mathbf{h}\mathbf{t} | x_{u,i}) \right\} dt_1 \cdots dt_q \right. \\ & \quad \left. \cdot \mathbb{E} \left\{ \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \middle| x_{u,i} \right\} \right] \\ &= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g}) p_{u,i}(\mathbf{g}')} \cdot \int \left\{ \prod_{s=1}^q \frac{1}{h_s^2} K(t_s) K \left( \frac{g_s - g'_s}{h_s} + t_s \right) p(o_{u,i} = 1, \mathbf{g} | x_{u,i}) + O(\sum_{s=1}^q h_s) \right\} dt_1 \cdots dt_q \right. \\ & \quad \left. \cdot \mathbb{E} \left\{ \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \middle| x_{u,i} \right\} \right] \\ &= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \int \prod_{s=1}^q \frac{1}{h_s} K(t_s) K \left( \frac{g_s - g'_s}{h_s} + t_s \right) dt_1 \cdots dt_q \cdot \mathbb{E} \left\{ \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \middle| x_{u,i} \right\} \right] \cdot \{1 + O(\sum_{s=1}^q h_s)\} \\ &= \mathbb{E} \left[ \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \int \prod_{s=1}^q \frac{1}{h_s} K(t_s) K \left( \frac{g_s - g'_s}{h_s} + t_s \right) dt_1 \cdots dt_q \cdot \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \right] \cdot \{1 + O(\sum_{s=1}^q h_s)\}. \end{aligned}$$

Thus, define  $\bar{K}(\frac{\mathbf{g} - \mathbf{g}'}{\mathbf{h}}) = \int \prod_{s=1}^q K(t_s) K \left( \frac{g_s - g'_s}{h_s} + t_s \right) dt_1 \cdots dt_q$ , then

$$\begin{aligned} & \mathbb{E} \left\{ \left( \int \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot p_{u,i}(\mathbf{g})} \pi(\mathbf{g}) d\mathbf{g} \right)^2 \right\} \\ &= \int \mathbb{E} \left[ \int \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \frac{1}{\prod_{s=1}^q h_s} \bar{K} \left( \frac{\mathbf{g} - \mathbf{g}'}{\mathbf{h}} \right) \cdot \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \pi(\mathbf{g}') d\mathbf{g}' \right] \cdot \{1 + O(\sum_{s=1}^q h_s)\} \cdot \pi(\mathbf{g}) d\mathbf{g} \\ &\triangleq \int \varphi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g} \frac{1}{\prod_{s=1}^q h_s} (1 + o(1)), \end{aligned}$$

where

$$\varphi(\mathbf{g}) = \int \frac{1}{p_{u,i}(\mathbf{g}')} \cdot \bar{K} \left( \frac{\mathbf{g} - \mathbf{g}'}{\mathbf{h}} \right) \cdot \delta_{u,i}(\mathbf{g}) \delta_{u,i}(\mathbf{g}') \pi(\mathbf{g}') d\mathbf{g}'$$

is a bounded function of  $\mathbf{g}$ . Therefore,

$$\mathbb{V}\{\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})\} = \frac{1}{|\mathcal{D}| \prod_{s=1}^q h_s} \int \varphi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g} + o\left(\frac{1}{|\mathcal{D}| \prod_{s=1}^q h_s}\right).$$

□

**Theorem 8** (Optimal bandwidth of N-IPS and N-DR with Multi-dimensional Treatment Representation). *Under Assumptions 1–3 and 6, and assume that  $h = h_1 = \cdots = h_q$ , then*

(a) *the optimal bandwidth for the N-IPS estimator in terms of the asymptotic mean-squared error is*

$$h_{\text{N-IPS}}^* = \left[ \frac{\int \varphi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g}}{4|\mathcal{D}| \left( \frac{1}{2} \mu_2 \sum_{s=1}^q \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i}=1, \mathbf{g}_{u,i}=\mathbf{g} | x_{u,i})}{\partial g_s^2} \cdot \delta_{u,i}(\mathbf{g}) \right] \cdot \pi(\mathbf{g}) d\mathbf{g} \right)^2} \right]^{1/(4+q)},$$

where  $\varphi(\mathbf{g})$  is defined in Theorem 6.

(b) the optimal bandwidth for the N-DR estimator in terms of the asymptotic mean-squared error is

$$h_{\text{N-DR}}^* = \left[ \frac{\int \psi(\mathbf{g}) \pi(\mathbf{g}) d\mathbf{g}}{4|\mathcal{D}| \left( \frac{1}{2} \mu_2 \sum_{s=1}^q \int \mathbb{E} \left[ \frac{\partial^2 p(o_{u,i}=1, \mathbf{g}_{u,i}=\mathbf{g} | x_{u,i})}{\partial g_s^2} \cdot \{\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})\} \right] \cdot \pi(\mathbf{g}) d\mathbf{g} \right)^2} \right]^{1/(4+q)},$$

where  $\psi(\mathbf{g})$  is defined in Theorem 6.

*Proof of Theorem 7.* This conclusion can be derived directly from a similar argument of the proof of Theorem 4.  $\square$

Then, we obtain the uniform tail bound of the N-IPS and N-DR estimators with multi-dimensional treatment representation.

**Theorem 9** (Uniform Tail Bound of N-IPS and N-DR with Multi-dimensional Treatment Representation). *Under Assumptions 1–3, 5, and 6, and suppose that  $K(t) \leq M_K$ , then for all  $\hat{\mathbf{R}} \in \mathcal{F}$ , we have with probability at least  $1 - \eta$ ,*

(a)

$$\sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathbb{E}[\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})] - \mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}) \right| \leq \frac{2M_p(M_K)^q}{\prod_{s=1}^q h_s} \mathcal{R}(\mathcal{F}) + \frac{5M_p M_\delta (M_K)^q}{2 \prod_{s=1}^q h_s} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)},$$

(b)

$$\sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathbb{E}[\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})] - \mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}}) \right| \leq \frac{2M_p(M_K)^q}{\prod_{s=1}^q h_s} \mathcal{R}(\mathcal{F}) + \frac{5M_p M_{|\delta-\hat{\delta}|} (M_K)^q}{2 \prod_{s=1}^q h_s} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)}.$$

*Proof of Theorem 8.* It is sufficient to prove the uniform tail bound of  $\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})$ , and the result for  $\mathcal{L}_{\text{DR}}^{\text{N}}(\hat{\mathbf{R}})$  can be derived by an exactly similar argument.

Note that

$$\begin{aligned} & \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}}) - \mathbb{E}\{\mathcal{L}_{\text{IPS}}^{\text{N}}(\hat{\mathbf{R}})\} \right| \\ & \leq \int \pi(\mathbf{g}) \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left\{ \frac{\mathbb{I}(o_{u,i}=1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right. \\ & \quad \left. - \mathbb{E} \left\{ \frac{\mathbb{I}(o_{u,i}=1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right| d\mathbf{g}. \end{aligned}$$

For all prediction model  $\hat{\mathbf{R}} \in \mathcal{F}$  and  $\mathbf{g}$ , we have

$$\frac{1}{|\mathcal{D}|} \left| \frac{\mathbb{I}(o_{u,i}=1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u,i}(\mathbf{g})} - \frac{\mathbb{I}(o_{u',i'}=1) \cdot \mathbf{K}((\mathbf{g}_{u',i'} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u',i'}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u',i'}(\mathbf{g})} \right| \leq \frac{M_p M_\delta (M_K)^q}{\prod_{s=1}^q h_s |\mathcal{D}|},$$

then applying Lemma 2 yields that with probability at least  $1 - \eta/2$

$$\begin{aligned} & \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathbb{E} \left\{ \frac{\mathbb{I}(o_{u,i}=1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} - \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left\{ \frac{\mathbb{I}(o_{u,i}=1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right| \\ & \leq \mathbb{E} \left[ \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathbb{E} \left\{ \frac{\mathbb{I}(o_{u,i}=1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} - \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left\{ \frac{\mathbb{I}(o_{u,i}=1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right| \right] \\ & \quad + \frac{M_p M_\delta (M_K)^q}{2 \prod_{s=1}^q h_s} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)} \\ & \leq \frac{M_p (M_K)^q}{\prod_{s=1}^q h_s} 2\mathbb{E}[\mathcal{R}(\mathcal{F})] + \frac{M_p M_\delta (M_K)^q}{2 \prod_{s=1}^q h_s} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)}, \end{aligned}$$

where the last inequality holds by Lemma 3 and

$$\frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u,i}(\mathbf{g})} \leq \frac{M_p(M_K)^q}{\prod_{s=1}^q h_s}.$$

Applying (A.5) yields that with probability at least  $1 - \eta$

$$\begin{aligned} & \sup_{\hat{\mathbf{R}} \in \mathcal{F}} \left| \mathbb{E} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} - \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} \left\{ \frac{\mathbb{I}(o_{u,i} = 1) \cdot \mathbf{K}((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot \delta_{u,i}(\mathbf{g})}{\prod_{s=1}^q h_s \cdot \hat{p}_{u,i}(\mathbf{g})} \right\} \right| \\ & \leq \frac{2M_p(M_K)^q}{\prod_{s=1}^q h_s} \mathcal{R}(\mathcal{F}) + \frac{5M_p M_\delta(M_K)^q}{2 \prod_{s=1}^q h_s} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)}, \end{aligned}$$

which implies that the conclusion (a) by noting that  $\int \pi(\mathbf{g}) d\mathbf{g} = 1$

□

Let

$$\mathbf{R}^\dagger = \arg \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{IPS}}^N(\hat{\mathbf{R}}), \quad \mathbf{R}^\ddagger = \arg \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{DR}}^N(\hat{\mathbf{R}}).$$

The following Corollary 10 shows the generalization bounds of the N-IPS and N-DR estimators.

**Corollary 10.** (Generalization Bound of N-IPS and N-DR with Multi-dimensional Treatment Representation) Under the conditions in Theorem 8, we have with probability at least  $1 - \eta$ ,

(a)

$$\begin{aligned} \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}^\dagger) & \leq \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}) + \mu_2 \left[ \sum_{s=1}^q h_s^2 \int \mathbb{E} \left\{ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})}{\partial g_s^2} \cdot \delta_{u,i}(\mathbf{g}) \right\} \pi(\mathbf{g}) d\mathbf{g} \right] \\ & \quad + \frac{4M_p(M_K)^q}{\prod_{s=1}^q h_s} \mathcal{R}(\mathcal{F}) + \frac{5M_p M_\delta(M_K)^q}{\prod_{s=1}^q h_s} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)} + o\left(\sum_{s=1}^q h_s^2\right). \end{aligned}$$

(b)

$$\begin{aligned} \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}^\ddagger) & \leq \min_{\hat{\mathbf{R}} \in \mathcal{F}} \mathcal{L}_{\text{ideal}}^N(\hat{\mathbf{R}}) + \mu_2 \left[ \sum_{s=1}^q h_s^2 \int \mathbb{E} \left\{ \frac{\partial^2 p(o_{u,i} = 1, \mathbf{g}_{u,i} = \mathbf{g} | x_{u,i})}{\partial g_s^2} \cdot (\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g})) \right\} \pi(\mathbf{g}) d\mathbf{g} \right] \\ & \quad + \frac{4M_p(M_K)^q}{\prod_{s=1}^q h_s} \mathcal{R}(\mathcal{F}) + \frac{5M_p M_{|\delta - \hat{\delta}|}(M_K)^q}{\prod_{s=1}^q h_s} \sqrt{\frac{2}{|\mathcal{D}|} \log\left(\frac{4}{\eta}\right)} + o\left(\sum_{s=1}^q h_s^2\right). \end{aligned}$$

*Proof of Proposition 2.* This conclusion can be derived directly from the proof of Proposition 1. □

## H PSEUDO-CODES FOR PROPENSITY LEARNING, N-IPS, N-DR-JL AND N-MRDR-JL

The learning paradigm for propensity is shown in Algorithm 1, and the learning paradigm for N-IPS, N-DR-JL and N-MRDR-JL are shown in Algorithms 2-4. When learning the propensity model  $p_{u,i}(\mathbf{g})$ , since  $\frac{1}{p_{u,i}(\mathbf{g})} = \frac{c}{\mathbb{P}(o=1|\mathbf{x})} \cdot \frac{\mathbb{P}(L=1)}{\mathbb{P}(L=0)} \cdot \frac{\mathbb{P}(L=0|\mathbf{x},\mathbf{g})}{\mathbb{P}(L=1|\mathbf{x},\mathbf{g})} \propto \frac{1}{\mathbb{P}(o=1|\mathbf{x})} \cdot \frac{\mathbb{P}(L=0|\mathbf{x},\mathbf{g})}{\mathbb{P}(L=1|\mathbf{x},\mathbf{g})}$ , therefore the well-trained model that estimates  $\mathbb{P}(L = 1 | \mathbf{x}, \mathbf{g})$  is enough for the propensity estimation. The constant  $c$  and  $\frac{\mathbb{P}(L=1)}{\mathbb{P}(L=0)}$  can be ignored when learning prediction and imputation model. For the N-MRDR-JL learning algorithm, the parameter  $\phi_{\mathbf{g}}$  of the imputation model is optimized by minimizing the following loss:

$$\mathcal{L}_e^{\text{N-MRDR}}(\hat{\mathbf{R}}|\mathbf{g}) = |\mathcal{D}|^{-1} \sum_{(u,i) \in \mathcal{D}} \frac{\mathbb{I}(o_{u,i} = 1) \cdot (1 - p_{u,i}(\mathbf{g})) \cdot K((\mathbf{g}_{u,i} - \mathbf{g})/\mathbf{h}) \cdot (\delta_{u,i}(\mathbf{g}) - \hat{\delta}_{u,i}(\mathbf{g}))^2}{h \cdot p_{u,i}^2(\mathbf{g})}.$$

Compared to the  $\mathcal{L}_e^{\text{N-DR}}(\hat{\mathbf{R}}|\mathbf{g})$ , the  $\mathcal{L}_e^{\text{N-MRDR}}(\hat{\mathbf{R}}|\mathbf{g})$  loss has variance reduction property.

**Output:** the well-trained prediction model  $f_{\theta}(\mathbf{x})$ .**I CASE STUDY ON A LARGE INDUSTRIAL DATASET**

We conduct two experiments on a large scale industrial dataset **KuaiRec** to verify the existence of the neighborhood effect. For the first experiment, we investigate whether the similarity of watching ratio between two friend users in the social network is higher than the similarity of watching ratio between two non-friend users. We use the small dataset in **KuaiRec**, which is a fully exposed dataset containing 4,676,570 watching ratio records from 1,411 users to 3,327 videos. Meanwhile, we also use the social network data in **KuaiRec**. Specifically, we first find friends for each user in the social network and calculate the mean of the distance of their watching ratio vectors. For example, if the friends of user  $U_1$  are  $U_2$  and  $U_3$ , then the mean of the distance is calculated as  $(\text{dist}(W_{U_1}, W_{U_2}) + \text{dist}(W_{U_1}, W_{U_3}))/2$ , where  $\text{dist}(\cdot, \cdot)$  is a distance metric and  $W_{U_i}$  is the watching ratio vector of user  $U_i$ . Then we randomly select non-friend user and calculate the mean of the watching ratio vector distance between each user and his non-friend users. In our experiment, the number of friend user and non-friend user are equal. In the above example, since the number of friends of  $U_1$  is two, we randomly select two non-friends users of  $U_1$  and calculate the mean of the watching ratio vector between  $U_1$  and two non-friend users. Figure 3(a) shows the experiment result. The distances between the friend user watching ratio vectors are smaller than the distances between the non-friend watching ratio vectors, which verifies the existence of the neighborhood effect.

For the second experiment, since  $(u, i)$  is reasonable to be viewed as the neighborhood of  $(u, i')$ , we explore the effect of a user's historical interaction on current behavior. For example, the videos that a user has watched before will have an impact on the watching ratio from the user to the current video. The intuition behind the experiment is that users who have seen better videos than the current video are more likely to have a low watching ratio towards the current video. Specifically, we first compute the average watching ratio of 3,327 videos based on the fully exposed small dataset and assign each video a ranking based on that watching ratio. Meanwhile, we rank each user interaction from past to present based on the timestamps. Next, we explore the connection between the watching ratio of the  $K + 1$  video seen by the user and the previous  $K$  videos. If more than half of the  $K$  videos have higher ranking than the  $K + 1$  video, then  $(u, i_{K+1})$  is denoted as a "better" user-item pair, and vice versa as a "worse" user-item pair. Then we compute the difference between the watching ratio of the

"better" and "worse" user-item pair and the average watching ratio of video  $i_{K+1}$ , respectively. Table 3 shows the mean values of the differences with varying  $K$ . Figure 3(b) shows the distribution of the differences when  $K = 15$ . The results show that "better" user-item pairs are more likely to have a low watching ratio, i.e., **the treatment of the neighbor units  $(u, i')$  will affect the outcome of  $(u, i)$ , which verifies the existence of the arrow from  $g_{u, i}$  to  $r_{u, i}$  in Figure 1.**

Table 3: The mean values of the differences with varying item numbers  $K$ .

$K$	3	4	5	10	15	20
Items with better quality	-0.048	-0.082	-0.059	-0.049	-0.070	-0.096
Items with worse quality	+0.188	+0.241	+0.125	+0.138	+0.153	+0.159

## J SEMI SYNTHETIC EXPERIMENT DETAILS

Following the previous studies (Guo et al., 2021; Schnabel et al., 2016; Wang et al., 2019), we set propensity  $p_{u,i} = p\alpha^{\max(0,4-r_{u,i})}$  for each user-item pair. To investigate the effect of the neighborhood effect, we randomly block-off some user rows and item columns to get the mask matrix  $\mathbf{M}$ . Specifically, we let  $m_u \sim \text{Bern}(p_u)$ ,  $\forall u \in \mathcal{U}$ ,  $m_i \sim \text{Bern}(p_i)$ ,  $\forall i \in \mathcal{I}$  and  $m_{u,i} = m_u \cdot m_i$ , where  $\text{Bern}$  denotes the Bernoulli distribution and  $p_u$  and  $p_i$  are the mask ratio for user and item. These  $p_u$  and  $p_i$  are set to 1 in RQ1. For RQ2, we set  $p_u = (|\mathcal{U}| - n_u)/|\mathcal{U}|$  and  $p_i = (|\mathcal{I}| - n_i)/|\mathcal{I}|$ , where  $|\mathcal{U}|$  and  $|\mathcal{I}|$  are the total user number and item number and  $n_u$  and  $n_i$  are the mask number for user and item, respectively. In our experiment,  $n_u \in \{50, 150, 250, 350\}$  and  $n_i = n_u \cdot |\mathcal{I}|/|\mathcal{U}|$ . Then we obtain the propensity matrix  $\mathbf{P}$  with  $p_{u,i} = p_{u,i} \cdot m_{u,i} = p\alpha^{\max(0,4-r_{u,i})} \cdot m_{u,i}$ . For different mask number, we adjust  $p$  to ensure the total observed sample is 5% of the entire matrix (Schnabel et al., 2016). **The different  $n_u$  and  $n_i$  corresponding to the different strength of the neighborhood effect.** Next, following the previous studies (Guo et al., 2021; Wang et al., 2019) we add a uniform distributed variable to introduce noise to obtain the estimate propensities  $\frac{1}{\hat{p}_{u,i}} = \frac{\beta}{p_{u,i}} + \frac{1-\beta}{p_o}$ , where  $\beta$  is from a uniform distribution  $U(0, 1)$  and  $p_o = \frac{1}{|\mathcal{D}|} \sum_{(u,i) \in \mathcal{D}} o_{u,i}$ .

## K REAL-WORLD EXPERIMENT DETAILS AND MORE EXPERIMENT RESULTS

**Dataset.** We verify the effectiveness of the proposed estimators on three real-world datasets: **Coat**<sup>2</sup> contains 6,960 MNAR ratings and 4,640 missing-at-random (MAR) ratings. Both MNAR and MAR ratings are from 290 users and 300 items. **Yahoo! R3**<sup>3</sup> contains 311,704 MNAR ratings and 54,000 MAR ratings. The MNAR ratings are from 15,400 users and 1,000 items, and the MAR ratings are from the first 5,400 users and 1,000 items. For both datasets, ratings are binarized to 1 if  $r_{u,i} \geq 3$ , and 0 otherwise. In addition, we use a public large-scale industrial dataset, **KuaiRec**<sup>4</sup> (Gao et al., 2022), which is a fully exposed dataset and contains 4,676,570 video watching ratio records from 1,411 users for 3,327 videos. The records less than 2 are set to 0, and otherwise are set to 1.

**Experimental Details.** All the experiments are implemented on PyTorch with Adam as the optimizer. For all experiments, we use NVIDIA GeForce RTX 3090 as the computing resource. We tune the learning rate in  $\{0.005, 0.01, 0.05, 0.1\}$ , weight decay in  $\{1e-6, 5e-6, \dots, 5e-3, 1e-2\}$  and the batch size in  $\{128, 256, 512, 1024, 2048\}$  for **Coat** and  $\{1024, 2048, 4096, 8192, 16384\}$  for **Yahoo! R3** and **KuaiRec**. For bandwidth value, we tune bandwidth value in  $\{20, 40, 60, 80, 100\}$  for **Coat**,  $\{500, 1000, 1500, 2000, 2500\}$  for **Yahoo! R3** and  $\{50, 75, 100, 125, 150\}$  for **KuaiRec**.

**Effect of Varying Bandwidth.** Table 4 shows the results for N-IPS-NB with varying bandwidth on all three datasets. The experiment result shows that the N-IPS-NB achieves the best performance when the bandwidth is moderate, because it will ensure a proper weight for N-IPS-NB estimator.
