# Subword Attention and Post-Processing for Rare and Unknown Contextualized Embeddings

Anonymous ACL submission

#### Abstract

 Word representations are an important aspect of Natural Language Processing (NLP). Represen- tations are trained using large corpuses, either as independent static embeddings or as part of a deep contextualized model. While word em- beddings are useful, they struggle on rare and unknown words. As such, a large body of work has been done on estimating rare and unknown words. However, most of the methods focus on static embeddings, with few models focused on contextualized representations. In this work, we propose SPRUCE, a rare/unknown embed- ding architecture that focuses on contextualized representations. This architecture uses subword attention and embedding post-processing com-**bined with the contextualized model to produce**  high quality embeddings. We then demonstrate 018 these techniques lead to improved performance in most intrinsic and downstream tasks.

# **020** 1 Introduction

 Word representations are an important aspect of NLP. While initially, word embeddings were trained separately and inserted into task specific architectures ("static" embeddings), modern ap- proaches use deep architectures to generate con- [t](#page-4-1)extualized representations [\(Devlin et al.,](#page-4-0) [2018;](#page-4-0) [Pe-](#page-4-1) [ters et al.,](#page-4-1) [2018;](#page-4-1) [Liu et al.,](#page-4-2) [2019\)](#page-4-2). A weakness of static representations is that they only exist for a trained vocabulary; there are no representations for unknown words. While deep contextualized models can theoretically produce a new representa- tion, [\(Schick and Schütze,](#page-5-0) [2020\)](#page-5-0) demonstrated that these representations for unknown/rare words are of poor quality, implying that rare/unknown words are still a challenge for contextualized embeddings. In response, there have been attempts to create new representations for these words. While there has been a large body of work on static embed- dings, less has been focused on contextualized em- beddings, especially approaches that incorporate recent innovations enhancing static rare/unknown

estimation. Motivated by this, we propose a new **042** architecture for rare/unknown estimation of con- **043** textualized embeddings. This model incorporates **044** subword attention and embedding post-processing **045** for higher quality estimates. We call this ap- **046** proach Subword Attention and Postprocessing for **047** Rare and Unknown Contextualized Embeddings **048** (SPRUCE). **049**

### 2 Related Work **<sup>050</sup>**

Rare/unknown word representations have been **051** well studied in static word embeddings. Early ap- **052** proaches used context sentences to estimate new **053** word embeddings [\(Herbelot and Baroni,](#page-4-3) [2017;](#page-4-3) **054** [Lazaridou et al.,](#page-4-4) [2017;](#page-4-4) [Horn,](#page-4-5) [2017;](#page-4-5) [Arora et al.,](#page-4-6) **055** [2017;](#page-4-6) [Mu and Viswanath,](#page-4-7) [2018;](#page-4-7) [Khodak et al.,](#page-4-8) **056** [2018\)](#page-4-8), while other approaches use the rare words' **057** morphemes/subwords to estimate the embedding **058** [\(Bojanowski et al.,](#page-4-9) [2017;](#page-4-9) [Sasaki et al.,](#page-5-1) [2019;](#page-5-1) [Pin-](#page-4-10) **059** [ter et al.,](#page-4-10) [2017\)](#page-4-10). The most effective approaches **060** [c](#page-5-2)ombine context sentences and subwords [\(Schick](#page-5-2) **061** [and Schütze,](#page-5-2) [2019c](#page-5-2)[,a;](#page-5-3) [Hu et al.,](#page-4-11) [2019;](#page-4-11) [Patel and](#page-4-12) **062** [Domeniconi,](#page-4-12) [2020,](#page-4-12) [2023\)](#page-4-13). The combined model **063** *SubAtt* [\(Patel and Domeniconi,](#page-4-13) [2023\)](#page-4-13), for instance, **064** uses transformer self attention [\(Vaswani et al.,](#page-5-4) **065** [2017\)](#page-5-4) on context like other models, but also uses **066** transformer self attention on the subword represen- **067** tations, leading to strong results. Rare/unknown **068** words have also been studied on contextualized **069** embeddings, with the goal of constructing new **070** representations for use in the initial embedding **071** layer of the contextualized deep model. While less- **072** studied than static embeddings, there have been **073** attempts to effectively estimate rare/unknown con- **074** textualized embeddings. The current state-of-the- **075** art approach on contextualized models is BERTRAM **076** [\(Schick and Schütze,](#page-5-5) [2019b\)](#page-5-5); BERTRAM constructs **077** the context representations using the BERT archi- **078** tecture. It then combines these representations us- **079** ing the attention mechanism from Attentive Mim- **080** icking [\(Schick and Schütze,](#page-5-3) [2019a,](#page-5-3) [2020\)](#page-5-0). It uses **081**

 learned subwords to estimate the rare/unknown embedding, and then inputs this estimate into the **BERT** model for each context sentence. BERTRAM has been shown to output strong rare/unknown em- beddings for use in a BERT architecture. How- ever, contextualized rare/unknown words are un- derstudied, and models don't incorporate recent innovations found in static embedding equivalents. In response to this, we propose SPRUCE, a model that incorporates the strengths of previous static models like *SubAtt* and contextualized models like BERTRAM to create a new architecture that is state-of-the-art in most rare/unknown evaluation tasks.

# **<sup>095</sup>** 3 Model

**We now present SPRUCE<sup>[1](#page-1-0)</sup>. We focus on estimat-** ing rare and unknown embeddings with the BERT [\(Devlin et al.,](#page-4-0) [2018\)](#page-4-0) model, although this can be adapted to any deep model. We combine aspects of the previous state-of-the-art model BERTRAM [\(Schick and Schütze,](#page-5-5) [2019b\)](#page-5-5) with attention on the subword input, similar to the one proposed in static [w](#page-4-13)ord embeddings model *SubAtt* [\(Patel and Domeni-](#page-4-13) [coni,](#page-4-13) [2023\)](#page-4-13) but has not been previously used in con- textualized models. In addition, we train SPRUCE on post-processed embeddings, with top PCA com- ponents removed. A diagram of SPRUCE is shown in Figure [1.](#page-2-0)

### **109** 3.1 Pretrained Aspects

 Similar to BERTRAM, we start with pretraining a context half and a subword half of the model sepa- rately. We use the same architectures pretrained in BERTRAM for SPRUCE.

#### **114** 3.2 **SPRUCE** Context Architecture

**115** Similar to BERTRAM, we extract BERT representations for each context sentence  $C_i$ . We then use 117 these to calculate our new representations using **118** Attentive Mimicking [\(Schick and Schütze,](#page-5-3) [2019a,](#page-5-3) **119** [2020\)](#page-5-0).

$$
120\\
$$

$$
v_{C_i} = BERT(C_i) \tag{1}
$$

$$
v_{ctx_1} = \sum_{i=1}^{C} \rho(C_i) v_{C_i}
$$
 (2)

122 where  $\rho(C)$  is calculated using the attention mech- [a](#page-5-3)nism used in Attentive Mimicking (see [\(Schick](#page-5-3) [and Schütze,](#page-5-3) [2019a\)](#page-5-3) for more details). Next, we calculate a second context representation, using a transformer encoder self attention layer, denoted as **126**  $Encoder_{ctx}$ . We take the mean of this result:  $127$ 

$$
v_{C_2} =Encoder_{ctx}(v_C, v_C, v_C)
$$
 (3) 128

$$
v_{ctx_2} = \frac{1}{|v_{C_2}|} \sum_{i} v_{C_{2i}} \tag{4}
$$

This approach yields two context representations, **130**  $v_{ctx_1}$  and  $v_{ctx_2}$ . **131**

### 3.3 **SPRUCE** Subword Architecture **132**

Unlike BERTRAM, which creates a subword estimate **133** and then inserts it into each context sentence, we **134** also incorporate the subword representation at the **135** end of the model. In addition, we apply attention **136** [o](#page-4-13)n the subwords. This was proposed in [\(Patel and](#page-4-13) **137** [Domeniconi,](#page-4-13) [2023\)](#page-4-13) for static embeddings; ours **138** is the first architecture to do this with contextual- **139** ized ones. We use two subword representations. **140** First, in an effort to match the context processing 141 of BERT, we apply transformer encoder layers to **142** the pretrained subword embeddings. We use 12 **143** layers in an effort to match the BERT architecture. **144** We then take the mean of those representations: **145**

$$
v_{S_2} = Encoder_{sub_{12}}(v_S, v_S, v_S)
$$
 (5)

$$
v_{sub1} = \frac{1}{|v_{S_2}|} \sum_{i} v_{S_{2i}} \tag{6}
$$

(6) **147**

(8) **154**

where  $V_S$  is the set of character ngram subwords  $148$ that make up the target rare/unknown word. Sec- **149** ondly, to match the context half of the architecture, **150** we use another transformer self attention layer, and **151** then take the mean: **152** 

$$
v_{S_3} = Encoder_{sub1}(v_{S_2}, v_{S_2}, v_{S_2})
$$
 (7)

$$
v_{sub2} = \frac{1}{|v_{S_3}|} \sum_{i} v_{S_{3i}} \tag{8}
$$

This yields two subword representations,  $v_{sub1}$  and  $155$  $v_{sub2}$ . . **156**

### 3.4 Combining Subword and Context **157**

We experimented combining the four values in various ways, but found that a hierarchical gating ap- **159** proach worked best. We use gate functions origi- **160** nally proposed in [\(Schick and Schütze,](#page-5-2) [2019c\)](#page-5-2), ap- **161** plied multiple times to combine each piece. First, **162** we combine the context representations with each 163 other and the subword representations with each **164** other. We then combine the final context and final **165**

<span id="page-1-0"></span> $1$ Link to code to be added after review

<span id="page-2-0"></span>

Figure 1: Model Architecture

**166** subword representations:

167 
$$
v_{ctx_{final}} = \alpha_c v_{ctx_1} + (1 - \alpha_c)v_{ctx_2}
$$
 (9)

168 
$$
v_{subfinal} = \alpha_s v_{sub1} + (1 - \alpha_s) v_{sub2}
$$
 (10)

$$
v_{final} = \alpha_f v_{ctx_{final}} + (1 - \alpha_f) v_{sub_{final}} \tag{11}
$$

170 with weights of each  $\alpha$  is calculated as follows:

171 
$$
\alpha_j = \sigma(w_j^T[v_{j_1}, v_{j_2}] + b)
$$
 (12)

172 where  $w_j \in R^{2d}$  and b is a bias value. Our final 173 **representation is**  $v_{final}$ **. During training, this is 174** compared to the original embedding (we refer to 175 this as  $v_{qold}$ ) using Mean Squared Error as the loss.

## **176** 3.5 Post-Processing Label Embeddings

 Word embeddings tend to share some common directions. These common directions carry lit- tle semantic content, and can distract from the [m](#page-4-7)eaningful components in embeddings. [\(Mu and](#page-4-7) [Viswanath,](#page-4-7) [2018\)](#page-4-7) and [\(Arora et al.,](#page-4-6) [2017\)](#page-4-6) proposed post-processing word embeddings in order to im- prove their performance in various tasks. The post- processing approach removes top PCA [\(Pearson,](#page-4-14) [1901\)](#page-4-14) components from each embedding, removing less meaningful aspects of the embeddings. While post-processing is generally studied on static word embeddings, [\(Sajjad et al.,](#page-5-6) [2022\)](#page-5-6) demonstrated that this post-processing shows improvement in contex- tualized embeddings as well. Motivated by this, we propose training SPRUCE on post-processed BERT embeddings. The goal is to train the model to output embeddings that carry meaningful content. Training on post-processed embeddings should force the model to focus on those instead of com- mon directions found in the embeddings. To this end, we remove the top seven components from the BERT embeddings before using them to super-vise training. We note that this is only done when

<span id="page-2-1"></span>

#### Table 1: WNLaMPro (MRR)

training SPRUCE; when inserting the estimated em- **200** beddings into the BERT architecture, we do not **201** post-process the common embeddings. The goal **202** is to estimate embeddings that work well in a stan- **203** dard BERT model, and as a result, we do not post- **204** process there. **205** 

# 4 Experiments **<sup>206</sup>**

## 4.1 Model Training **207**

We extract gold standard embeddings of frequent **208** words from the embedding layer of the BERT **209** model for use as labels. However, as discussed **210** in [\(Schick and Schütze,](#page-5-0) [2020\)](#page-5-0), most embeddings **211** use subword tokenization, and as such, an embed- **212** ding doesn't exist for all words in the vocabulary. **213** In order to get gold standard embeddings for these **214** [w](#page-5-0)ords, we use One Token Approximation [\(Schick](#page-5-0) **215** [and Schütze,](#page-5-0) [2020\)](#page-5-0) to get the equivalent embed- **216** ding. We extract context sentences from the West- **217** bury Wikipedia Corpus (WWC) [\(Shaoul,](#page-5-7) [2010\)](#page-5-7) for **218** each gold standard word. **219**

### 4.2 Baselines and Hyperparameters **220**

[W](#page-5-5)e compare our approach to BERTRAM [\(Schick and](#page-5-5) **221** [Schütze,](#page-5-5) [2019b\)](#page-5-5), the current state-of-the-art. For **222** both models, we pretrain a context only and sub- **223** word only model, using the same parameters used **224** in [\(Schick and Schütze,](#page-5-5) [2019b\)](#page-5-5) with one difference; **225** we increase the subword dropout from 0.1 to 0.3, 226 which we found improved results in both models. **227** 

<span id="page-3-1"></span>

	An $EM$	Bio-NER	<b>CoNLL 2003</b>	MovieMIT	<b>POS</b>	Rare-NER
<b>BERTRAM</b>	0.3652	0.7241	0.6617	0.6295	0.2449	0.2592
$BFRTRAM + PCA$	0.3579	0.7252	0.6633	0.6657	0.2346	0.2652
<b>SPRUCE</b>	0.3867	0.7399	0.6963	0.6801	0.4761	0.2874

Table 2: Downstream Tasks - Macro F1 of Rare/Unknown Words

 We train each model for 10 epochs with a learning rate of 1e-6 (which we found to be best out of 1e-6, 1e-5, and 1e-4). For each model, we train a version based on the standard embeddings, and one trained on post-processed embeddings (denoted "+ PCA"). 10 trials of each model were trained. As we don't have an evaluation set, we test the model saved at each epoch in the evaluation task, and take the best performance. We conduct significance test- ing using one-way ANOVA with a post-hoc Tukey HSD test. We use a p-value threshold equal to 0.05. We present the best result and any result not sig- nificantly different in bold. We also compare each model with its PCA post-processed version, where we present the significant best with an underline.

#### **243** 4.3 Evaluation Tasks

 Intrinsic Tasks First, we conduct intrinsic evalua- tion of our estimated embeddings. The first task we [s](#page-5-0)tudy is the WNLaMPRo task, proposed in [\(Schick](#page-5-0) [and Schütze,](#page-5-0) [2020\)](#page-5-0). This task contains various patterns containing vocabulary split by frequency (frequent, medium, and rare). This task then uses simple prompts to measure performance. For exam- ple, a frequent pattern may evaluate the word pre- dicted in "A lime is a ", while a similar rare pattern may evaluate the word predicted in "A kumquat is a ". The performance is based on where the real word ranks in the predicted probabilities, mea- sured with Mean Reciprocal Rank (MRR). In our evaluation, we use the models to estimate on rare and medium words, and judge the performance on the new embeddings. We present the results of WNLaMPro in Table [1.](#page-2-1) As shown in the re- sults, SPRUCE outperforms BERTRAM in rare word performance, but has a weaker performance with medium frequency words. Additionally, we find that PCA post-processing improves both BERTRAM and SPRUCE in both rare and medium words. These results demonstrate SPRUCE's strength at estimat- ing strong rare word representations, along with post-processing label effectiveness at improving embedding performance in both rare and medium **270** words.

Downstream Evaluation While intrinsic eval- **271** uation of estimated embeddings is important, the **272** main motivation of using deep contextualized mod- **273** els like BERT is for finetuning on downstream **274** tasks. To this end, we evaluate rare/unknown word **275** performance on various downstream tasks, simi- **276** [l](#page-4-13)ar to the procedure done in [\(Patel and Domeni-](#page-4-13) **277** [coni,](#page-4-13) [2023\)](#page-4-13). However, here we insert the estimated **278** embeddings into a standard BERT model, then **279** finetune the model<sup>[2](#page-3-0)</sup> on the training set (with the  $280$ best model picked by the validation set). We then **281** evaluate the performance on the test set for that **282** task. Each task presented here is a word level **283** task, which allows us to focus analysis on the **284** rare/unknown words. We focus on six downstream **285** tasks; five NER tasks: AnEM, [\(Ohta et al.,](#page-4-15) [2012\)](#page-4-15), **286** [B](#page-5-8)io-NER [\(Kim et al.,](#page-4-16) [2004\)](#page-4-16), CoNLL 2003 [\(Sang](#page-5-8) **287** [and De Meulder,](#page-5-8) [2003\)](#page-5-8), MovieMIT [\(Liu et al.,](#page-4-17) **288** [2013\)](#page-4-17), and Rare-NER [\(Derczynski et al.,](#page-4-18) [2017\)](#page-4-18) **289** and one parts-of-speech task POS [\(Ritter et al.,](#page-5-9) **290** [2011\)](#page-5-9). We present the results in Table [2.](#page-3-1) We find **291** that SPRUCE significantly outperforms BERTRAM in **292** all tasks. This demonstrates SPRUCE's high per- **293** formance at estimating rare and unknown words. **294** Interestingly, PCA post-processing does not seem **295** to affect results here in most cases, except for an im- **296** provement in BERTRAM in the MovieMIT task and **297** weaker performance in SPRUCE in the POS task. **298** We posit that this lack of impact is due to the fact 299 that post-processing improves estimated embed- **300** dings on a finer grained basis. For the downstream **301** tasks, which care more about general features, the **302** improvement gained by post-processing may not **303** have as much impact. **304** 

## 5 Conclusion **<sup>305</sup>**

We propose SPRUCE, an architecture that uses  $306$ deep contextualized models to estimate new repre- **307** sentations of rare/unknown words for use in those **308** models. We show the strength of SPRUCE in intrin- **309** sic and downstream tasks. **310** 

<span id="page-3-0"></span><sup>&</sup>lt;sup>2</sup>We freeze the embedding layer so we can evaluate the quality of embeddings, not finetuning.

# **<sup>311</sup>** Limitations

 This work has some limitations. Similar to pre- vious work, task diversity of downstream tasks is limited. Due to ability to focus on rare/unknown words, word level tasks are desirable for analysis, and therefore five out of the six tasks are named entity recognition tasks.

# A Implementation Details **<sup>478</sup>**

All experiments were conducted using Pytorch **479** [\(Paszke et al.,](#page-4-19) [2019\)](#page-4-19) and Huggingface [\(Wolf et al.,](#page-5-10) **480** [2020\)](#page-5-10) libraries. Our implementation was heavily **481** based on the BERTRAM <sup>[3](#page-5-11)</sup> code. 482
