Paper under double-blind review

ABSTRACT

We present MM1.5, a new family of multimodal large language models (MLLMs) designed to enhance capabilities in text-rich image understanding, visual referring and grounding, and multi-image reasoning. Building upon the MM1 architecture, MM1.5 adopts a data-centric approach to model training, systematically exploring the impact of diverse data mixtures across the entire model training lifecycle. This includes high-quality OCR data and synthetic captions for continual pre-training, as well as an optimized visual instruction-tuning data mixture for supervised finetuning. Our models range from 1B to 30B parameters, encompassing both dense and mixture-of-experts (MoE) variants, and demonstrate that careful data curation and training strategies can yield strong performance even at small scales (1B and $3B$).^{[1](#page-0-0)} Through extensive empirical studies and ablations, we provide detailed insights into the training processes and decisions that inform our final designs, offering valuable guidance for future research in MLLM development.

1 INTRODUCTION

026 027 028 029 030 031 032 033 034 Multimodal Large Language Models (MLLMs) have emerged as an increasingly active research topic in recent years. Closed-source models, such as GPT-4o [\(Islam & Moushi, 2024\)](#page-13-0), GPT-4V [\(OpenAI,](#page-17-0) [2024\)](#page-17-0), Gemini-1.5 [\(Team et al., 2023;](#page-18-0) [Reid et al., 2024\)](#page-17-1), and Claude-3.5 [\(Anthropic, 2023\)](#page-10-0), have demonstrated remarkable capabilities in advanced multimodal understanding. Meanwhile, opensource models, such as the LLaVA series of work [\(Liu et al., 2023b](#page-16-0)[;a;](#page-16-1) [2024a;](#page-16-2) [Li et al., 2024c\)](#page-14-0), InternVL2 [\(Chen et al., 2024b\)](#page-11-0), Cambrian-1 [\(Tong et al., 2024a\)](#page-18-1) and Qwen2-VL [\(Bai et al., 2023;](#page-10-1) [team, 2024\)](#page-18-2), are rapidly narrowing the performance gap. There has also been growing interest in developing models capable of understanding single-image, multi-image, and video data using a single set of model weights [\(Li et al., 2024c\)](#page-14-0). Further discussion of recent works is in Appendix [A.1.](#page-22-0)

035 036 Building upon MM1 [\(McKinzie et al., 2024\)](#page-17-2), we introduce MM1.5, a new family of MLLMs carefully designed to enhance a set of core capabilities. Specifically, we focus on the following aspects.

• OCR. MM1.5 supports arbitrary image aspect ratios and resolutions of up to 4 Megapixels. By incorporating carefully selected OCR data to enhance text comprehension across different training stages, MM1.5 excels at understanding text-rich images.

• Visual referring and grounding. MM1.5 offers robust, fine-grained image understanding, extending beyond text prompts to interpret *visual* prompts such as points and bounding boxes. Moreover, MM1.5 can generate grounded responses by grounding text output with image bounding boxes. This capability is notably under-explored in most open-source models (*e.g.*, LLaVA-OneVision [\(Li](#page-14-0) [et al., 2024c\)](#page-14-0) and Phi-3-Vision [\(Abdin et al., 2024b\)](#page-10-2)), and even in strong proprietary models like GPT-4o, which rely on set-of-mark (SoM) prompting [\(Yang et al., 2023\)](#page-19-0) to reference image regions.

• Multi-image reasoning. MM1.5 benefits from large-scale interleaved pre-training, resulting in strong in-context learning and multi-image reasoning capabilities right out of the box. We further improve its capabilities via supervised fine-tuning (SFT) on additional multi-image data.

049 050 051 052 Our primary focus is on the most efficient model scales, 1B and 3B, together with their corresponding Mixture-of-Experts (MoE) variants, and demonstrates that even relatively small MLLMs can achieve competitive performance on various downstream tasks. Furthermore, we demonstrate that the

¹Additionally, we introduce two specialized variants: MM1.5-Video, designed for video understanding, and MM1.5-UI, tailored for mobile UI understanding, detailed in Appendix [A.7](#page-30-0) and [A.8](#page-31-0) correspondingly.

Figure 1: Recipe for building MM1.5. Model training contains three stages: (i) large-scale pretraining with low-resolution images (378×378) , (ii) continual pre-training with high-resolution (up to 4 Megapixels) OCR data and synthetic captions, and (iii) supervised fine-tuning (SFT). At each stage, we aim to identify the optimal data mix and assess the impact of each data type.

MM1.5 recipe exhibits strong scaling behavior all the way to 30B parameters, achieving competitive performance across a wide range of benchmarks.

071 072 073 074 075 Building performant MLLMs is a highly empirical endeavor. While the overarching goal and the high-level training procedure are well-defined, the finer details of their execution remain unclear. In developing MM1.5, we choose to retain the same model architecture as MM1 [\(McKinzie et al.,](#page-17-2) [2024\)](#page-17-2), enabling us to focus on refining and investigating the intricacies of our data-centric training recipes. Our attention is centered on the following key aspects:

- **076 077 078 079** • Continual Pre-training. We introduce an additional high-resolution continual pre-training stage preceding the SFT stage, which we found crucial for boosting text-rich image understanding performance. We ablate the impact of two kinds of data: (i) text-rich OCR data, focusing on detailed transcription of text within images; and (ii) high-quality synthetic image captions.
	- SFT. While considerable prior work discusses SFT data for MLLMs, there is still limited exploration into how each category of SFT data can affect the final model's performance. In particular, the impact of data supporting each capability on other capabilities is understudied. We conduct extensive ablations to identify trade-offs and synergies, ultimately constructing a mixture from public datasets that contributes to well-balanced performance across a wide set of capabilities.
		- Dynamic High-resolution. Furthermore, for *high-resolution* image encoding, we follow the popular any-resolution approach, dynamically dividing the image into sub-images [\(Li et al., 2023i;](#page-15-0) [Zhang et al., 2024b\)](#page-20-0), and conduct thorough ablations to refine key details in our design.

089 090 091 092 093 094 Unlike most open-source models focusing solely on SFT [\(Liu et al., 2023b](#page-16-0)[;a;](#page-16-1) [2024a\)](#page-16-2), MM1 demonstrated strong zero-shot and few-shot learning capabilities through large-scale pre-training. In developing MM1.5, we aim to retain these strengths and more effectively transfer them to the SFT stage. To achieve this, We further extend MM1's pre-training by exploring the impact of text-only data and optimizing the ratio of different pre-training data types. This approach improves performance on knowledge-intensive benchmarks and enhances overall multimodal understanding capabilities.

095 096 097 098 Our main contributions are summarized as follows: (i) We introduce MM1.5, a family of MLLMs that include both dense models (ranging from 1B to 30B) and MoE variants. (ii) We conduct a thorough empirical study detailing the process and decisions leading to our final design choices. (iii) MM1.5 excels in handling a wide range of multimodal tasks, from general-domain to text-rich image understanding, coarse- to fine-grained understanding, and single- to multi-image reasoning.

2 RECIPE FOR BUILDING MM1.5

104 In this work, beyond pre-training and SFT stages as in MM1 [\(McKinzie et al., 2024\)](#page-17-2), we introduce a continual pre-training stage with high-quality OCR data and synthetic captions. As outlined in Figure [1,](#page-1-0) to obtain the best data recipe,

106 107 • We first present comprehensive ablations of our SFT data mixture (Section [2.2\)](#page-2-0). We categorize the SFT data into multiple groups based on the capabilities they aim to support. We carefully evaluate the impact of datasets from each category and adjust the ratio to balance different core capabilities.

- **108 109 110 111 112 113 114 115 116 117 118 119 120 121 122 123** • To further enhance model performance, especially for text-rich image understanding, we further ablate the data choices for continual pre-training (Section [2.3\)](#page-5-0). This includes 45M rich OCR data and 7M high-quality captions from public or generated by a MM1-based image captioner. • We also provide detailed ablation regarding dynamic image splitting, also known as AnyRes [\(Liu](#page-16-2) [et al., 2024a\)](#page-16-2) (Section [2.4\)](#page-6-0), for high-resolution image comprehension. Finally, to enhance performance on knowledge-heavy benchmarks like MMMU [\(Yue et al., 2023a\)](#page-20-1), we further study the impact of pre-training data (Appendix [A.2\)](#page-22-1). 2.1 EMPIRICAL SETUP FOR ABLATIONS Unless otherwise noted, we follow the default settings below in our ablation studies. Model architecture and data preprocessing. Wefollow MM1 [\(McKinzie et al., 2024\)](#page-17-2) and use the same architecture, focusing on the 3B dense model for all the ablation studies in this section. Specifically, • Static image splitting [\(Lin et al., 2023b\)](#page-16-3) is enabled with 4 sub-image splits (plus an overview
- **124 125** image), and each sub-image is resized to 672×672 resolution via position embedding interpolation. Note that we did not use dynamic image splitting during ablation for faster iteration of experiments.
	- As to the encoding of multi-image data, we enable image splitting only when the current training sample contains fewer than three images to avoid excessively long sequence lengths.
- **128 129 130 131** • Similar to capabilities introduced in Ferret [\(You et al., 2023\)](#page-19-1), MM1.5 directly supports referring and grounding. When requested, MM1.5 can produce bounding boxes in its textual output to ground its responses. Additionally, the model can interpret references to points and regions in the input image in the form of referring coordinates and bounding boxes.
	- The CLIP image encoder and the LLM backbone are based on in-house models, with C-Abstractor [\(Cha et al., 2024\)](#page-11-1) serving as the vision-language connector.

134 135 136 Model optimization. For both continual pre-training and SFT, we set the batch size as 256. We use the AdaFactor optimizer with a peak learning rate of 1e-5 and a cosine decay of 0. For continual pre-training, we train a maximum of 30k steps. During SFT, all models are optimized for one epoch.

137 138 139 140 141 142 Continual pre-training. Models are initialized with the MM1 pre-trained checkpoint. By default, we conduct continual pre-training on 45M high-resolution OCR data (including PDFA, IDL, Renderedtext [\(Laurençon et al., 2024a\)](#page-14-1) and DocStruct-4M [\(Hu et al., 2024a\)](#page-13-1)) at this stage. In each training batch, data is equally sampled from those four datasets. Similar to the SFT stage, we use static image splitting, dividing each image into five sub-images, with each sub-image resized to 672×672 resolution. We find that this high-resolution setup is essential for continual pre-training.

144 145 146 147 148 149 SFT data categorization. Grouping datasets into categories can be helpful for data balancing and simplifying the analysis [\(Laurençon et al., 2024a;](#page-14-1) [Tong et al., 2024a\)](#page-18-1). At a high level, we cluster datasets into *single-image*, *multi-image*, and *text-only* categories based on the number of images presented in each example. For the single-image group, we further classify each dataset into the following sub-categories: *general*, *text-rich*, *refer&ground*, *science*, *math* and *code*. See Table [5](#page-24-0) in Appendix [A.3](#page-23-0) for the details of each category used for the ablation study, and Figure [8](#page-24-1) for an overview of the group categories.

150 151 152 153 154 155 156 157 Evaluation benchmarks. We group our benchmarks into categories based on what capabilities a benchmark primarily measures. Our benchmark groups include general, text-rich, refer&ground, knowledge, and multi-image. See Table [6](#page-25-0) in Appendix [A.4](#page-23-1) for more details. We propose *Category Average Score*, the average score of all benchmark numbers for each sub-category, to represent the average performance on that capability. We focus on the categories of general, text-rich, and knowledge, as these capabilities are widely considered essential for MLLMs. To evaluate a model's impact on these capabilities, we refer to a *MMBase* score, defined as the average scores on general, text-rich, and knowledge categories. Details of the evaluation metrics are provided in Appendix [A.4.](#page-23-1)

158

126 127

132 133

- **159 160** 2.2 SFT ABLATIONS
- **161** To determine the optimal SFT recipe, we first study the impact of different data categories in Section [2.2.1,](#page-3-0) followed by investigating how to best mix all the data in Section [2.2.2.](#page-3-1)

Figure 2: Impact of different SFT data categories to different model capabilities (general, textrich, knowledge, and refer&ground). Text-rich data significantly improves text-rich and knowledge benchmarks on average. Science data improves knowledge average score. Referring and grounding data enables this capability.

Figure 3: Impact of α (x-axis) for different data categories to a model's different capabilities. The selected ratio is marked with red "x". α denotes the data ratio of the target category (science, math, code, refer&ground (R&G)) when compared with the general category.

2.2.1 IMPACT OF DIFFERENT DATA CATEGORIES

 In this subsection, we focus on evaluating the single-image data category. We begin by assessing the general data category and then progressively evaluate the impact of adding other sub-categories individually. During training, we mix data from different sub-categories and construct each training batch by randomly sampling data from the corresponding mixture. We compare models using each capability with the *Category Average Score*.

 Our results are summarized in Figure [2.](#page-3-2) We observe that adding text-rich data can significantly improve the performance on text-rich and knowledge benchmarks. The inclusion of math data follows a similar trend, though we observe a lesser degree of improvement in the text-rich average score. When science data is added, we observe the expected improvement in the knowledge benchmarks, alongside a minor improvement in text-rich performance. Adding the code category yields a slight increase in the text-rich average score, while the performance on other benchmarks does not improve. Including the refer&ground data instills the model with referring and grounding capability, but we also observe slight regression in all other capability categories.

 2.2.2 DATA MIXTURE RATIO STUDY

 We first study the mixing ratio within the single-image categories. Since directly mixing the general and text-rich data based on their data sizes shows strong results across a variety of benchmarks (see Figure [2\)](#page-3-2), we use this combination as the starting point to study how to mix other categories to this set. Then, we combine the entire single-image set with multi-image and text-only sets with sampling weights of w_{single} , w_{multi} and w_{text} , respectively, where $w_{\text{single}} + w_{\text{multi}} + w_{\text{text}} = 1$.

 Mixture of single-image data. Directly mixing all datasets from different categories may not be ideal due to imbalanced numbers of data samples across different sub-categories. For example, the size of the general data category is around $68\times$ the size of the science data category. In this study, we use the general data category as the reference, and upsample/downsample data from a target category, such that in each training batch, the data ratio from the general and target category is $1:\alpha$.

Figure 4: Impact of the mixing ratio for text-only and multi-image SFT data. The selected ratio is marked with red "x".

Figure 5: Ablation study of mixing all the SFT data. *Base Mixture* denotes general, text-rich and knowledge (science, math and code). The "Average" column represents the performance averaged across the preceding five benchmark categories.

 To measure the average impact of α, we propose *MMBase* score, an average over general, text-rich, and knowledge average scores, for model comparison. As shown in Figure [3,](#page-3-3) we vary the α for different data categories. For science, math, and code categories, we find the best ratio of α to be 0.1, 0.5, and 0.2, respectively. As shown in Section [2.2.1,](#page-3-0) the refer&ground data is the main driver for improving referring and grounding benchmarks. Therefore, besides the *MMBase* score, we also include the Refer&Ground average score as another metric for the α selection. As summarized in Figure [3\(](#page-3-3)d), the *MMBase* score will drop slightly, while the Refer&Ground average score increases significantly. With that, we select $\alpha = 2.0$ as a good trade-off.

 Mixture of single-image, multi-image, and text-only data. Now, we study the mixture ratios, w_{single} , w_{multi} and w_{text} . Enumerating all combinations between the three ratios will incur significant computational cost. Therefore, we instead separately ablate w_{text} and w_{multi} for text-only and multiimage data, respectively, to evaluate how sensitive our model is to these ratios. Finally, w_{single} is determined by $1 - w_{\text{text}} - w_{\text{multi}}$.

 Similar to the single-image mixture study, we also start with the combination of general and text-rich data and enumerate different values for w_{multi} and w_{text} . For text-only data, we tested w_{text} from 0 to 0.2. Figure [4\(](#page-4-0)left) shows that varying different values for w_{text} has minor effects on the model's base capabilities in general. We select $w_{text} = 0.1$ to allocate a higher weight for single-image data for potential performance improvements.

 For multi-image data, we use the multi-image average score (evaluated on multi-image benchmarks in Table [6\)](#page-25-0) as an additional metric to assess a model's capability of handling multi-image tasks. Results are summarized in Figure [4\(](#page-4-0)right). We observe that increasing the sampling ratio of multi-image data would introduce a performance drop of the base capabilities as indicated by the decreased number of the *MMBase* score, while the multi-image average score increases. We select $w_{\text{multi}} = 0.1$ since it introduces a surge in the multi-image average score.

 Mixing multiple categories. Based on the studies above, we present three mixtures, the *Base* mixture, *Single-image* mixture, and *All* mixture, and analyze their trade-offs. The *Base* mixture includes the general, text-rich, science ($\alpha_{\text{science}} = 0.1$), math ($\alpha_{\text{math}} = 0.5$) and code ($\alpha_{\text{code}} = 0.2$) data groups. The *Single-image* mixture additionally adds refer&ground data ($\alpha_{rg} = 2.0$) to the *Base* mixture. All

(a) Impact of input resolution. OCR data is used for all (b) Impact of data source. the continual pre-training experiments.

.51

Figure 6: Ablation study of continual pre-training. Average Score indicates the *MMBase* score. Cont. PT denotes continual pre-training.

 mixture includes all data from single-image, multi-image, and text-only data, with $w_{\text{single}} = 0.8$, $w_{\text{multi}} = 0.1$, and $w_{\text{text}} = 0.1$.

 Our results are summarized in Figure [5.](#page-4-1) The first three columns indicate that including refer&ground and multi-image data slightly reduces average performance on text-rich, knowledge, and general benchmarks. The fourth column shows that adding refer&ground data significantly boosts referring and grounding performance, while the fifth column highlights that adding multi-image data greatly improves multi-image benchmarks. The final column reveals that our optimized mixture achieves the best overall performance, balancing all capabilities across benchmarks.

 2.3 CONTINUAL PRE-TRAINING ABLATIONS

 Unless otherwise specified, we use OCR data (45M in total), including PDFA, IDL, Renderedtext [\(Laurençon et al., 2024a\)](#page-14-1) and DocStruct-4M [\(Hu et al., 2024a\)](#page-13-1) in a high-resolution setting (1344×1344) for continual pre-training. During the SFT stage, all continual pre-trained models in this section are fine-tuned with data from the *Base Mixture* including general, text-rich, knowledge (science, math, and code) with their selected mixture ratios as described in Section [2.2.2.](#page-3-1)

 Impact of image resolution. Intuitively, higher-resolution images are preferable when training with OCR data. We first ablate the impact of image resolution during this stage by setting up two baselines, continual pre-training with 378×378 and 756×756 resolutions, respectively. For the former, we disabled both image splitting and position embedding interpolation (our CLIP image encoder natively supports image resolution of 378×378). For the latter, we enabled image splitting and turn-off position embedding interpolation. The results are shown in Figure [6\(](#page-5-1)a). Note that the final SFT stage always uses image resolution 1344×1344 across these experiments, so the training only differs with respect to the image resolution used in continual pre-training.

 We can clearly see that using a setting of 1344×1344 image resolution for continual pre-training achieves the best overall performance. Decreasing resolution consistently leads to lower final scores. In particular, continual pre-training with 378×378 resolution can underperform a model without continual pre-training. We hypothesize this is due to insufficient visible detail at lower resolutions, which may hinder the model's ability to effectively learn from the document-based OCR data in the continual pre-training mixture.

 Impact of OCR data and synthetic captions. Besides OCR data, high-quality synthetic image captions [\(Chen et al., 2023c;](#page-11-2) [Li et al., 2024a\)](#page-14-2) are also widely considered useful for pre-training. To study its impact, we use our default setting except for the data used in continual pre-training. We study two synthetic caption datasets: LLaVA-Recap-3M [\(Li et al., 2024a\)](#page-14-2) and ShareGPT4V-PT [\(Chen et al., 2023c\)](#page-11-2), and their combination with our OCR data. When we combine ShareGPT4V-PT or LLaVA-Recap-3M with our OCR data, we equally sample data from individual datasets in each training batch. Results are presented in Figure [6\(](#page-5-1)b). We observe that all continual pre-trained models perform better than the baseline without continual pre-training. However, we did not find conclusive evidence that these high-quality synthetic captions improved performance over the arguably simpler

324 325 326 327 Table 1: Ablation on the image resolution and the number of image tokens used in dynamic image splitting. *n* denotes the total number of sub-images. Row 3: $(n_{\min}, n_{\max}) = (4, 4)$; Row 4-7: $(n_{\min}, n_{\max}) = (9, 9)$. Image encoder resolution: (i) 378 × 378: no position embedding interpolation; (*ii*) 672 \times 672: with position embedding interpolation.

Row #	Mode	\boldsymbol{n}	#image tokens (per sub-img / total)	Image Enc. Resolution	Effective Resolution	Text-rich	Knowledge	General	Refer & Ground	Average
			144/144	672×672	0.45MP	49.4	53.6	62.6	71.3	59.2
	Static		144/720	672×672	1.8MP	57.7	53.8	64.4	74.8	62.7
			144/720	672×672	1.8MP	58.6	53.7	64.1	74.0	62.5
		10	81/810	378×378	1.3MP	57.6	53.3	62.9	74.0	62.0
	Dvnamic	10	81/810	672×672	4.1MP	58.3	53.8	64.3	74.9	62.8
6		10	144/1440	378×378	1.3MP	58.5	54.0	63.2	74.5	62.6
		10	144/1440	672×672	4.1MP	59.8	54.0	64.5	75.2	63.3

OCR data. While prior studies [\(Li et al., 2024c\)](#page-14-0) show synthetic captions boost performance, our results indicate further investigation into their exact impact is needed.

Therefore, we further investigate the impact of synthetic captions generated through self-training for even larger scales (up to 7M) and more controllable styles, using a pre-trained MM1 model fine-tuned on human-annotated captions, similar to [\(Fang et al., 2024\)](#page-12-0). This new dataset showed some promise in certain settings, see Appendix [A.5](#page-25-1) for details. We defer further study of this topic to future work.

343 344 345

346

2.4 DYNAMIC IMAGE SPLITTING ABLATIONS

347 348 349 350 351 352 Dynamic image splitting. Processing high-resolution images is essential for text-rich image understanding. In *static* image splitting [\(Lin et al., 2023b\)](#page-16-3), images are split into a rigid 2×2 grid, which is often inefficient. Low-resolution images are splitted without any need, and images with non-square aspect ratios can result in sub-images being padding only. Therefore, we adopt a dynamic image splitting approach, which is common in the literature [\(Li et al., 2024a;](#page-14-2) [Dong et al., 2024b;](#page-11-3) [Hu et al.,](#page-13-1) [2024a;](#page-13-1) [Lin et al., 2023b;](#page-16-3) [Xu et al., 2024c;](#page-19-2) [Zhang et al., 2024d\)](#page-20-2), for MM1.5.

353 354 355 356 357 358 359 360 361 362 Given a minimum and maximum number of sub-images, n_{\min} and n_{\max} , consider the set of all candidate grids $G = \{(n_h, n_w) \in \mathbb{N} \mid n_{\min} \leq n_h \cdot n_w \leq n_{\max}\}\.$ Further, consider the resolution of the vision encoder r, and an input image resolution (h, w) . If there is a grid that can cover the image, we choose the grid that minimizes the amount of padding after longer side resizing to the grid, *i.e.*, $g^* = \arg \min_{(n_h, n_w) = g \in G} n_h n_w r^2 - h_g w_g$, subject to $n_h r \ge h_g \ge h$ and $n_w r \ge w_g \ge w$, where h_{α} , w_{α} denote the image height and width after longer side resizing the candidate grid. If no such grid exists, we choose the one that minimizes the resolution loss due to scaling the image down and fully covers the longer side resized image. Assume we allow up to 4 sub-images. With a static image splitting approach, all images use the grid $(2, 2)$. The dynamic splitting approach instead allows for the following grids: $\{(1, 1), (1, 2), (2, 1), (1, 3), (3, 1), (1, 4), (4, 1), (2, 2)\}.$

363 364 365 366 367 368 369 370 Global-Local Format. In addition to the sub-images, we always feed the original image with a longer side resized to the encoder resolution r to the model. This ensures that the model has a global understanding of the image. If the grid is $(1, 1)$, we omit the overview image. We consider two variants: (i) before: the overview image is put before the sub-images; (ii) after: the overview image is put after the sub-images. These variants yield different results because an autoregressive mask is used in the LLM decoder, and as such, the choice determines whether the decoder can attend to the overview image when processing the sub-images (i) or attend to the sub-images when processing the overview image (ii) .

371 372 373 374 Sub-image position indicator. Given that an input image is dynamically split into multiple subimages, we explore whether it is helpful to indicate the position of each sub-image in the original highresolution image to ensure the model can understand the original 2D image structure. Specifically, we consider two methods.

375 376 377 • Index. A tuple of (k, i, j) is used to represent sub-image position information, where k is the zero-indexed image number in the example (assuming there can be multiple images in a training sample), i and j are the one-index row and column id, $e.g., (0, 0, 0)$ is the overview image of image 0, and $(0, 2, 1)$ is the sub-image in the second row and first column, for image 0.

Row #	Train	(n_{\min}, n_{\max}) Inference	DocVOA	InfoVOA	Text-rich	Knowledge	General	Refer & Ground	Average

Table 2: Ablation on the image grid configuration (n_{\min}, n_{\max}) used in dynamic image splitting.

Table 3: Ablation on the sub-image position indicator and the position of the overview image. We set $(n_{\min}, n_{\max}) = (4, 4)$ for experiments.

Row #	Sub-img pos. indicator	Overview image pos.	DocVOA	InfoVOA	Text-rich	Knowledge	General	Refer & Ground	Average
	none	before	73.2	48.3	58.6	53.5	64.1	74.0	62.5
◠ ∠	seps	before	74.3	49.7	58.8	53.0	63.8	74.5	62.5
	index	before	73.4	48.6	58.6	52.7	63.4	74.8	62.4
	none	after	73.3	49.7	59.2	54.3	64.1	73.8	62.8

• Seps. Instead of using indexes, we use three text tokens. Specifically, "the overview image indicator, γ is the column separator, and γ is the row separator. The latter two tokens are inserted between the set of image tokens corresponding to each sub-image so that the original 2D image structure can be recovered from the flattened image token sequence.

407 408 409 410 411 Inference for higher resolution. The tuple (n_{\min}, n_{\max}) is used to decide the dynamic image splitting configuration for model training. During inference, it is possible to support even higherresolution image processing simply by increasing these parameters. For example, we explore training at $(n_{\min}, n_{\max}) = (4, 9)$ to save model training compute, while during inference, we use $(n'_{\min}, n'_{\max}) = (4, 16)$ to process images at even higher effective resolutions.

412 413 414 415 416 Findings. We use the final *Single-image Mixture* as our default experiment setting, including general, text-rich, knowledge (science, math and code), and refer&ground data. For fast iteration of experiments, all the models are initialized with the MM1 pre-trained checkpoint without continual pre-training. Following Figure [2,](#page-3-2) we report the average performance on text-rich, knowledge, general, and refer&ground benchmarks. Our findings are summarized as follows.

417 418 • Dynamic image splitting outperforms static splitting in text-rich tasks. Both image resolution and the number of sub-images, along with image token counts, are important (Table [1\)](#page-6-1).

- Regarding image grid configuration (Table [2\)](#page-7-0), dynamic image splitting with a larger n_{max} significantly improves performance on tasks with unusual aspect ratios, such as DocVQA and InfoVQA, especially when trained natively for it. Grounding performance is highly sensitive to grid size changes, and larger LLM backbones yield greater performance gains, with the 7B model showing larger improvements than the 3B model.
- **425 426 427 428** • In terms of position indicators (Table [3\)](#page-7-1), they are not strictly necessary for text-rich tasks, though they can be beneficial for specific tasks like DocVQA and InfoVQA. Additionally, placing the overview image after the sub-images improves performance, as it allows the decoder attention mask to attend to all sub-images more effectively.
- **430 431** • In practice, dynamic image splitting does not significantly increase the number of sub-images to process. In a sample of 100k examples, static splitting generates 500k sub-images, while dynamic splitting with $(n_{\min}, n_{\max}) = (4, 9)$ produces barely more, only 539k images in total.

429

432 433 3 FINAL MODEL AND TRAINING RECIPE

We collect the results from the previous ablations to determine the final recipe for MM1.5 training:

434 435 436

437

- Architecture. We use the same model architecture as MM1 [\(McKinzie et al., 2024\)](#page-17-2).
- Data and training pipeline. As summarized in Figure [1,](#page-1-0) MM1.5 is trained in three stages:
- **438 439 440 441 442 443** - Pre-training. The pre-training data comprises three parts: (i) 2B image-text pairs, (ii) 600M interleaved image-text documents with 1B images in total, and (iii) text-only data with 2T tokens. Except for the updated text-only data, the data remains unchanged from MM1 [\(McKinzie](#page-17-2) [et al., 2024\)](#page-17-2). However, the data ratio has been adjusted from 45:45:10 to 50:10:40, significantly downweighting the interleaved data (from 45% to 10%) while increasing the proportion of text-only data (from 10% to 40%) as discussed in Section [A.2.](#page-22-1)
- **444 445** – **Continual Pre-training.** We use 45M OCR data to enhance text-rich image understanding. Notably, we do not include additional synthetic image captions based on empirical results.
- **446 447 448 449 450** – SFT. We use the data illustrated in Figure [8](#page-24-1) and adopt the mixing ratios studied in Section [2.2.2.](#page-3-1) Our final mixture consists of 80% single-image data, 10% multi-image data, and 10% text-only SFT data. The single-image data can be further categorized into 37.2% text-rich data, 22.5% refer&ground data (VQA data enriched with bounding boxes and/or point coordinates), 11.3% general data, 5.6% math data, 2.3% code data, and 1.1% science data, totaling 80% of all data.
- **451 452 453 454 455** • **Dynamic high-resolution.** We set the image grid configuration $(n_{\min}, n_{\max}) = (4, 9)$, using an index for the sub-image position indicator and placing the overview image after the sub-images. Dynamic image splitting is only enabled when the current training sample has fewer than three images. The supported resolution reaches up to 4 Megapixels (approximately 2016×2016 for a square image, or 6048×672 for a long image).
- **456 457 458 459 460 461** We use the same image encoder and the LLM backbone from MM1 [\(McKinzie et al., 2024\)](#page-17-2), and keep them *unfrozen* during all the model training stages. For pre-training, we follow the exact same learning rate schedule as in MM1 [\(McKinzie et al., 2024\)](#page-17-2) and 200k training steps with sequence length 4096. For continual pre-training, we use a peak learning rate of 1e-5 with the cosine decay and 30k training steps for all the models (from 1B to 30B). For SFT, we use a peak learning rate of [2](#page-8-0)e-5 and 23k training steps for all the models. $²$ </sup>
- **462 463 464 465** Mixture-of-Experts (MoE). We introduce two MoE models, a 1B-MoE and a 3B-MoE, with 64 experts replacing dense layers every two layers. We use the same hyperparameters as those applied to the dense models for both scales and top-2 gating with a 0.01 load balance loss to encourage a better expert load balance and a 0.001 router z-loss for training stability [\(Lepikhin et al., 2021\)](#page-14-3).
- **466 467**

485

3.1 RESULTS

468 469 470 471 472 We evaluate our MM1.5 models across 35 multimodal benchmarks using an internal fork of lm-evalharness [\(Gao et al., 2023\)](#page-12-1), covering task categories ranging from general multimodal understanding, knowledge, text-rich, referring and grounding, multi-image reasoning, to in-context learning. Detailed results for each capability at various model sizes are further summarized in Table [7,](#page-27-0) [8,](#page-28-0) [9,](#page-28-1) [10,](#page-29-0) and [11,](#page-29-1) respectively. Below, we highlight a few key observations from Table [4.](#page-9-0)

473 474 475 476 477 MM1.5 represents a major upgrade over MM1. It delivers improvements across all model sizes and nearly all benchmarks, often by a substantial margin. For instance, MM1.5-30B boosts the MathVista from 39.4 to 55.6, DocVQA from 75.8 to 91.4, and InfoVQA from 47.3 to 67.3. It also offers much enhanced multi-image reasoning capability and introduces new capabilities not present in MM1, such as visual referring & grounding.

478 479 480 481 482 483 484 Both Dense and MoE model scaling are effective. First, scaling the dense model from 1B to 30B consistently improves performance, with benchmarks like AI2D increasing from 59.3 to 77.2 (see Table [7\)](#page-27-0). Second, both the 1B and 3B MoE models outperform their dense counterparts. Notably, the MM1.5-3B-MoE model can even surpass the MM1.5-7B model in knowledge, general, visual referring and grounding, and multi-image benchmarks, though it falls slightly behind on text-rich benchmarks. This suggests that MoE models show strong potential in integrating diverse capabilities compared to dense models.

 2 All models are trained using the AXLearn framework <https://github.com/apple/axlearn>

486 487 Table 4: Comparison with SOTA models on the selected benchmarks. Comparison of more benchmarks and broader baselines can be found in Table [7,](#page-27-0)[8,](#page-28-0)[9,](#page-28-1) [10](#page-29-0) and [11i](#page-29-1)n the Appendix.

503 504

505 506 507 508 509 MM1.5-1B is the state-of-the-art model at the 1B scale. While few models are available at this scale, MM1.5-1B clearly outperforms comparable models such as SPHINX-Tiny [\(Gao et al., 2024\)](#page-12-2). For reference, MM1.5-1B also significantly surpasses LLaVAOneVision-0.5B [\(Li et al., 2024c\)](#page-14-0) (*e.g.*, ScienceQA: 67.2 vs. 82.1, DocVQA: 70.0 vs. 81.0, see Table [7](#page-27-0) and [8\)](#page-28-0), but it should be stressed that this is of course an even smaller model and as such cannot be directly compared.

510 511 512 513 514 515 516 MM1.5-3B outperforms MiniCPM-V 2.0 and is competitive with InternVL2 and Phi-3-Vision. Compared to MiniCPM-V 2.0, MM1.5-3B achieves superior results on MathVista (38.7 vs. 44.4) and DocVQA (71.9 vs. 87.7) while also supporting visual referring and grounding, which MiniCPM-V lacks. It surpasses InternVL2-2B on general VQA and, although Phi-3-Vision (4.2B) has an edge on knowledge-based tasks like AI2D as in Table [7,](#page-27-0) MM1.5-3B excels on text-rich benchmarks (e.g., DocVQA: 83.3 vs. 87.7) and outperforms Phi-3-Vision in referring and grounding (see Table [9\)](#page-28-1), as well as in-context learning tasks (see Table [10\)](#page-29-0).

517 518 519 520 521 522 MM1.5 excels in visual referring and grounding. While most SOTA models focus on improving performance across general, knowledge, and text-rich benchmarks, few have integrated fine-grained image grounding and referring ability into their design. Even GPT-4o relies on set-of-mark prompting to demonstrate visual grounding capabilities. As shown in Table [9,](#page-28-1) MM1.5-3B outperforms Ferret-7B and is on par with Ferret-13B, both of which are fine-tuned specifically for referring and grounding tasks. Notably, our model inherently possesses these capabilities while still excelling in other areas.

523 524 525 526 527 528 529 530 MM1.5 excels in multi-image reasoning and in-context learning. As shown in Table [11,](#page-29-1) the MM1.5-1B model outperforms LLaVAOneVision-0.5B at the 1B scale. Similarly, at the 3B scale, MM1.5-3B significantly surpasses Phi-3-Vision. Additionally, we evaluate MM1.5's zero-shot transfer capability for video understanding using MVBench [\(Li et al., 2024h\)](#page-15-1), a benchmark designed for video tasks. Moreover, we evaluate MM1.5's ability of multimodal in-context learning on VL-ICL benchmark [\(Zong et al., 2024\)](#page-21-0). As shown in Table [10,](#page-29-0) our models outperform others in in-context learning. In Section [A.7,](#page-30-0) we will further introduce MM1.5-Video, a model variant specifically designed for video understanding.

531 532

4 CONCLUSION AND LIMITATION

533 534 535 536 537 538 539 In this work, we build on the insights of MM1 [\(McKinzie et al., 2024\)](#page-17-2) and introduce MM1.5, a family of highly performant generalist MLLMs. While MM1 focused on key pre-training choices, we improve post-pre-training techniques like continual pre-training, dynamic high-resolution image processing, and curation of our supervised fine-tuning datasets. Our extensive ablations show MM1.5 's strong performance in text-rich image understanding, visual grounding, and multi-image reasoning. Like most MLLMs, MM1.5 may produce harmful and counterfactual responses. Future efforts will aim to unify these capabilities for a stronger generalist model, with the hope of benefiting the community beyond specific architectures.

1188 1189 A APPENDIX

1190 1191 A.1 RELATED WORK

1192 1193 1194 1195 1196 1197 1198 1199 1200 1201 1202 Multimodal Large Language Models (MLLMs) [\(OpenAI, 2024;](#page-17-0) [Islam & Moushi, 2024;](#page-13-0) [Team et al.,](#page-18-0) [2023;](#page-18-0) [Li et al., 2024d;](#page-14-4) [Huang et al., 2023\)](#page-13-2) have recently emerged as a significant area of research focus. The development of MLLMs can be traced back to Frozen [\(Tsimpoukelli et al., 2021\)](#page-19-3) and Flamingo [\(Alayrac et al., 2022;](#page-10-3) [Awadalla et al., 2023\)](#page-10-4), with more recent advancements such as LLaVA [\(Liu et al., 2023b\)](#page-16-0) and MiniGPT-4 [\(Zhu et al., 2023\)](#page-21-1) introducing the concept of visual instruction tuning. The past year has witnessed a boom of open-source MLLMs, some of which claim to rival GPT-4o on certain benchmarks. Notable examples include Emu2 [\(Sun et al., 2023b;](#page-18-3) [2024\)](#page-18-4), VILA [\(Lin et al., 2024b\)](#page-15-2), Idefics2/3 [\(Laurençon et al., 2024a;](#page-14-1) [Laurençon et al., 2024a\)](#page-14-5), Cambrian-1 [\(Tong et al., 2024a\)](#page-18-1), InternLM-XComposer-2.5 [\(Dong et al., 2024a;](#page-11-4) [Zhang et al., 2024b\)](#page-20-0), InternVL2 [\(Chen et al., 2024c](#page-11-5)[;b\)](#page-11-0), MiniCPM-V [\(Yao et al., 2024b\)](#page-19-4), CogVLM2 [\(Wang et al., 2023a;](#page-19-5) [Hong et al., 2024a\)](#page-12-3), BLIP-3 [\(Li et al., 2023d;](#page-15-3) [Xue et al., 2024\)](#page-19-6), LLaVA-OneVision [\(Li et al., 2024e\)](#page-14-6), Llama3.1-V [\(Dubey et al., 2024\)](#page-12-4), and the latest Qwen2-VL [\(Bai et al., 2023\)](#page-10-1).

1203 1204 1205 1206 1207 1208 1209 1210 1211 1212 1213 1214 1215 Research in MLLMs has expanded across several fronts: (i) scaling up the pre-training data [\(Lin](#page-15-2) [et al., 2024b;](#page-15-2) [McKinzie et al., 2024;](#page-17-2) [Xue et al., 2024;](#page-19-6) [Awadalla et al., 2024;](#page-10-5) [Li et al., 2024j\)](#page-15-4) and supervised instruction-tuning data [\(Hu et al., 2024b;](#page-13-3) [Tang et al., 2024;](#page-18-5) [Laurençon et al., 2024a;](#page-14-1) [Tong](#page-18-1) [et al., 2024a\)](#page-18-1); *(ii)* enhancing high-resolution image comprehension [\(Lin et al., 2023b;](#page-16-3) [Li et al., 2023i;](#page-15-0) [Liu et al., 2024a;](#page-16-2) [Dong et al., 2024a;](#page-11-4) [Gao et al., 2024;](#page-12-2) [Ge et al., 2024;](#page-12-5) [Chen et al., 2024a;](#page-11-6) [Zhang et al.,](#page-20-2) [2024d;](#page-20-2) [Xu et al., 2024c;](#page-19-2) [Li et al., 2024l\)](#page-15-5); (iii) exploring various vision encoders [\(Tong et al., 2024b;](#page-18-6) [Shi et al., 2024\)](#page-18-7) and vision-language connectors [\(Cha et al., 2024;](#page-11-1) [Yao et al., 2024a;](#page-19-7) [Li et al., 2024k;](#page-15-6) [Cai et al., 2024\)](#page-11-7); (iv) using mixture-of-experts [\(Lin et al., 2024a;](#page-15-7) [Li et al., 2024g\)](#page-14-7); (v) extending LLaVA-like architectures to region-level [\(Wang et al., 2023b;](#page-19-8) [Zhao et al., 2023;](#page-20-3) [Zang et al., 2023;](#page-20-4) [Peng et al., 2023;](#page-17-3) [Chen et al., 2023b;](#page-11-8) [Zhang et al., 2023;](#page-20-5) [You et al., 2023;](#page-19-1) [Zhang et al., 2024a\)](#page-20-6) and pixel-level [\(Lai et al., 2024;](#page-14-8) [Rasheed et al., 2024;](#page-17-4) [Yuan et al., 2024;](#page-20-7) [Ren et al., 2024\)](#page-17-5) understanding, multi-image reasoning [\(Jiang et al., 2024;](#page-13-4) [Li et al., 2024e\)](#page-14-6), UI comprehension [\(You et al., 2024;](#page-20-8) [Hong et al., 2024b\)](#page-12-6), and video understanding [\(Lin et al., 2023a;](#page-15-8) [Xu et al., 2024a;](#page-19-9)[b\)](#page-19-10), among others.

1216 1217 1218 1219 1220 1221 1222 Among the extensive body of literature on MLLMs, MM1.5 distinguishes itself as a significant upgrade over its predecessor, MM1 [\(McKinzie et al., 2024\)](#page-17-2). The MM1.5 model family integrates a diverse set of core capabilities, including text-rich image understanding, visual referring and grounding, and multi-image reasoning. In contrast, recent general-purpose MLLMs such as Cambrian-1 [\(Tong](#page-18-1) [et al., 2024a\)](#page-18-1) and LLaVA-OneVision [\(Li et al., 2024e\)](#page-14-6) have shown less satisfactory performance in handling referring and grounding tasks, and GPT-4o has to rely on set-of-mark (SoM) prompting [\(Yang et al., 2023\)](#page-19-0) to understand image regions.

1223 1224 1225 1226 1227 1228 While several recent works have open-sourced detailed SFT data mixtures for public use [\(Laurençon](#page-14-1) [et al., 2024a;](#page-14-1) [Tong et al., 2024a\)](#page-18-1), the precise impact of each data category and the best recipe to combine them remain under-explored. This is particularly true for models requiring diverse capabilities. MM1.5 stands out by providing a comprehensive empirical study that presents mature recipes for building performant MLLMs. The extension of MM1.5 to mobile UI understanding further enhances the uniqueness of this work.

1229 1230 1231 1232 1233 Another emerging trend in the field is the development of lightweight MLLMs for potential edge deployment [\(Jin et al., 2024b;](#page-13-5) [Huang et al., 2024;](#page-13-6) [Beyer et al., 2024;](#page-10-6) [Lu et al., 2024;](#page-16-4) [Hinck et al.,](#page-12-7) [2024;](#page-12-7) [Li et al., 2024l;](#page-15-5) [Zhou et al., 2024;](#page-21-2) [He et al., 2024\)](#page-12-8). In MM1.5, models with 1B and 3B parameters are offered, which outperform similar-sized models, such as Phi-3-Vision [\(Abdin et al.,](#page-10-2) [2024b\)](#page-10-2) and MiniCPM-V [\(Yao et al., 2024b\)](#page-19-4).

1234

1235 A.2 PRE-TRAINING ABLATIONS

1236 1237 1238 1239 1240 1241 Beyond the SFT and continual pre-training, we emphasize the importance of large-scale, task-specific data used during pre-training in establishing robust foundations for models to effectively handle diverse tasks. For knowledge-heavy benchmarks like MMMU [\(Yue et al., 2023a\)](#page-20-1), we found that model performance is highly sensitive to its text comprehension capabilities. The LLM's ability to understand and process textual content is pivotal in addressing the complex reasoning and knowledgerepresentation challenges posed by these benchmarks, as also observed in Cambrian-1 [\(Tong et al.,](#page-18-1) [2024a\)](#page-18-1).

Figure 7: Performance comparison of all categories across different text-only data and pre-training data ratio. The figure highlights the performance improvement when replacing with *HQ-Text* data and the additional gains achieved by adjusting the ratio to 50:10:40. Note that the default setting for continual pre-training (OCR) and *All Mixture* for SFT are used for all models.

 We incorporated a higher-quality and more diverse set of text-only datasets, referred to as *HQ-Text*, introduced by [\(Gunter et al., 2024\)](#page-12-9), during the pre-training phase. These datasets were specifically curated to enhance the model's language capabilities by providing deeper and more varied textual contexts, with a focus on general knowledge, mathematics, and coding. This update aims to strengthen the model's ability in language-based reasoning.

 As shown in Figure [7,](#page-23-2) by simply replacing with the new data, the average score on knowledge improves by 0.85 points.

 In conjunction with the text-only datasets and the latest SFT recipes discussed in Section [2.2,](#page-2-0) we further refined our pre-training data composition. The original data ratio proposed in MM1 [\(McKinzie](#page-17-2) [et al., 2024\)](#page-17-2) was 45:45:10 for image-caption, interleaved image-text, and text-only data, respectively. Further experiments revealed that decreasing the amount of interleaved pre-training data and, respectively, increasing the weight of text-only data to a ratio of 50:10:40 resulted in improved performance across most tasks after SFT. We note that in contrast to pre-training ablations in MM1, for MM1.5, we conduct evaluations on downstream benchmarks post SFT to select our final pre-training mixture. We hypothesize that relying primarily on few-shot pre-training metrics may not be ideal, as the improvements on such evaluations may not effectively transfer to downstream performance. Our newly optimized data mix for MM1.5 not only enhances multimodal capabilities but also strengthens language understanding, leading to superior overall performance across benchmarks.

 With the updated mixture, performance on text-rich average increased by 0.85, knowledge average by 0.99, and refer&ground tasks by around 1.4, as shown in Figure [7.](#page-23-2) Although there was a slight decrease of 0.05 on multi-image datasets due to the lower weighting of interleaved data, we consider this trade-off reasonable for maintaining strong performance across all tasks.

-
- A.3 DETAILS OF SFT DATA FOR ABLATION & FINAL SFT MIXTURE

 As presented in Table [5,](#page-24-0) we use a subset of our final SFT data when conducting the ablation study. The MM1.5 final mixture is presented in Figure [8.](#page-24-1)

 A.4 MM1.5 BENCHMARK DETAILS

 Benchmarks used for MM1.5 evaluation are summarized in Table [6,](#page-25-0) where for each *Category Average Score*, we directly calculate the average of each metric number within that capability category as follows, with detailed evaluation metrics listed in Table [6.](#page-25-0)

• Text-rich Average Score: average score of the corresponding metric scores from WTQ, TabFact, OCRBench^{[4](#page-24-3)}, ChartQA^{[5](#page-24-4)}, TextVQA, DocVQA and InfoVQA.

³MME-Normalize is (MME-Perception + MME-Cognition)/2800 \times 100%.

⁴The accuracy of OCRbench is the total score normalized by $1000 \times 100\%$.

⁵Average of human part accuracy and augmented part accuracy.

1350 1351 Table 6: Details of benchmarks and their metrics used in MM1.5 ablation study. Benchmarks marked with (†) are excluded from the category average.

1372 1373

> • Refer & ground Average Score: average of the scores of Flickr30k, RefCOCO avg. and LVIS avg., where RefCOCO avg. is the average of RefCOCO A, RefCOCO B, RefCOCO+ A, RefCOCO+ B and RefCOCOg, and LVIS avg. is the average of point and box metrics.

> • Knowledge Average Score: average score of the corresponding metric scores from AI2D, ScienceQA, MathVista and MMMU.

• Multi-image average score: average of Qbench, Mantis, NLVR2, BLINK and MVBench metric scores.

1381 1382 1383 • MMBaseScore: average score of the *General Average Score*, *Text-rich Average Score* and *Knowledge Average Score*. This aggregated metric is used in Section [2](#page-1-1) to measure the impact of the general, text-rich, and knowledge capabilities of a model.

1384 1385

A.5 IMPACT OF SYNTHETIC CAPTIONS BY SELF-TRAINING

1386 1387 1388 1389 1390 1391 1392 1393 1394 1395 1396 1397 Besides using public captioning data mentioned in Section [2.3,](#page-5-0) we also follow [\(Fang et al., 2024\)](#page-12-0) to study the effect of self-training using synthetic captions. This is particularly important because captioning data generated by black-box commercial models can sometimes be difficult to scale and data from open models, such as from the LLaVA-NeXT family may be constrained by these model's inherent limitations. We develop a self-augmented image-caption data engine building on our previous work, MM1 [\(McKinzie et al., 2024\)](#page-17-2) with a goal to provide high quality captions in a computationally efficient manner. Specifically, we fine-tune a pre-trained 3B MM1-style model on a mix of synthetic and approximately 8k human-annotated paragraph-length image captions (approximately 70 tokens on average). We then apply this captioner at scale to 290 million web-crawled images with resolutions ranging from 512 to 1024px. Following the approach in [\(Liu et al., 2024a\)](#page-16-2), we perform concept filtering based on the generated captions, resulting in a dataset of 7 million high-quality captions, which includes numerous text-rich examples and alt-text-derived knowledge.

1398 1399 1400 1401 1402 1403 Building on this, we investigate the impact of the volume of synthetic caption data. The synthetic captions, ranging from 1.4 million to 7 million, show consistent improvements in model performance across various metrics, as illustrated in Figure [9.](#page-26-0) Specifically, a ratio of 0 on the x-axis indicates that no image-caption data is added to the original OCR dataset, while ratios ranging from 0.2 to 1.0 on the x-axis represent the proportion of the total 7M dataset included in the training. For example, a ratio of 0.2 corresponds to approximately 1.4M image-caption pairs added with the original OCR data while 1.0 denotes all 7M are added into training.

Figure 9: Impact of synthetic captions for continual pre-training the 3B model, building on top of the final MM1.5 strategy introduced in the main text, *i.e.*, including the OCR continual pre-training stage. We report the impact of adding incrementally more synthetic captions, up to 7M in total.

 In contrast to the ShareGPT4V-PT and LLaVA-Recap-3M captions as explored in Section [2.3,](#page-5-1) we find that adding our in-house synthetic captions to the OCR data mixture can lead to consistent improvement for continual pre-training.^{[6](#page-26-1)} We observe improvements in knowledge-related benchmarks and the aggregated *MMBase* scores that further scale with increased data volume. This is especially notable since our in-house captioner uses only a 3B model while LLaVA-Recap, for example, uses a 34B model for captioning.

 Our results suggest that while a comparatively simple OCR mixture represents a strong baseline for continual pre-training data, high-quality captions can still lead to further improvements. However, the quality, distribution, perhaps even style and length of the generated captions seem crucial to realize gains. While our in-house captions empirically outperformed publicly available data in our specific setting, further research is necessary as to what, specifically, these improvements are attributable to and whether further improvements can be achieved. This investigation goes beyond the scope of this paper, and we aim to study synthetic captioning further in future work.

A.6 COMPARISON WITH SOTA MODELS

 We compared our model with selected benchmarks in Section [3.](#page-8-1) Here, we present comparisons with more baselines on extensive benchmarks in Table [7](#page-27-0) (Knowledge & General), [8](#page-28-0) (Text-rich), Table [9](#page-28-1) (Refer & s Ground), Table [10](#page-29-0) (In-context Learning), and Table [11](#page-29-1) (Multi-image).

⁶Experiments in this section are based on the final recipe from Section [3,](#page-8-1) with slightly different settings compared to those in Section [A.2.](#page-22-1)

1592 1593 1594 Table 11: Comparison with SOTA models on multi-image benchmarks. The result with mark (†) in the row of GPT-4V is from GPT-4o. MVBench [Li et al.](#page-15-1) [\(2024h\)](#page-15-1) is treated as a multi-image benchmark to test the zero-shot transfer capability of MM1.5 to video understanding tasks.

1620 1621 A.7 MM1.5-VIDEO

1622 1623 1624 1625 1626 1627 1628 The multi-image reasoning capability shown in MM1.5 naturally leads us to develop MM1.5-Video for video understanding. It takes a video and an instruction as input and generates the response. For the inputs, we uniformly sample N frames from the video at an arbitrary length and feed them into the model as multi-image inputs without special frame assembly. Due to the token limits, we disable the dynamic image splitting for each frame, and the vision encoder generates the feature maps frame-by-frame independently. Specifically, we sample 24 frames for each video, and each frame is represented by 144 tokens.

1629 1630 1631 1632 We introduce two variants for MM1.5-Video. First, we build MM1.5-Video as a *training-free* model, which is achieved by directly adopting the pre-trained MM1.5 image models to video tasks without being fine-tuned on any video data. This saves a lot of computation resources and demonstrates MM1.5's capability of transferring knowledge to new domains.

1633 1634 1635 1636 1637 1638 1639 Second, we introduce the *supervised fine-tuning (SFT)* model where we fine-tune MM1.5 image models on video instruction-tuning datasets to improve its temporal modeling capability for video tasks. We use a mixture of public video datasets from ShareGPTVideo [\(Zhang et al., 2024c\)](#page-20-16) (556K), VideoChat2 [\(Li et al., 2023e\)](#page-15-14) (225K), and ActivityNet-QA [\(Yu et al., 2019\)](#page-20-17) (31.5K). These datasets contain a variety of videos types, spanning different tasks (*e.g.,* open-ended and multiple choice questions), viewpoints (*e.g.,* first- and third-person views), and lengths (*e.g.,* videos from a few seconds to tens of minutes).

1640

1641 A.7.1 BENCHMARKS AND METRICS

1642 1643 1644 We compare our video training-free and SFT models with state-of-the-art methods on multiple video question-answering (VideoQA) tasks and benchmarks.

1645 1646 1647 1648 1649 1650 1651 1652 Open-Ended Benchmarks evaluate the performance of a model to answer questions in a free-form style. For this task, we include ActivityNet-QA [\(Yu et al., 2019\)](#page-20-17) and VCGBench [\(Maaz et al., 2024\)](#page-16-15). Following prior work [\(Xu et al., 2024b\)](#page-19-10), we use $GPT-3.5-Turbo-0125$ to assess the accuracy and score for the prediction. Considering that the labeled answers of these two datasets are typically short (*e.g.,* one word or phrase), we also evaluate on the LLaVA-Hound [\(Zhang et al., 2024c\)](#page-20-16), which requires the model to generate more detailed answers. This is useful for assessing performance on tasks involving detailed video understanding. We follow their original setting to report the score from GPT-3.5-Turbo-0301 and consider a score value \geq 3 as correct for accuracy calculation.

1653 1654 1655 1656 1657 1658 1659 Multiple Choice Benchmarks require the model to pick the correct answer from multiple choices. For this evaluation, we include VideoMME [\(Fu et al., 2024b\)](#page-12-16), EgoSchema [\(Mangalam et al., 2024\)](#page-16-16), NExTQA [\(Xiao et al., 2021a\)](#page-19-16), and IntentQA [\(Li et al., 2023c\)](#page-15-15). VideoMME is a comprehensive evaluation dataset containing video from a few seconds to one hour in length. EgoSchema consists of egocentric videos and involves complex long-form temporal understanding and reasoning. NExTQA and IntentQA are collected from the same video source, but IntentQA focuses on predicting intents in daily social activities. For all these datasets, the accuracy of selecting the correct answer from the options is used as the evaluation metric.

- **1660**
- **1661 1662** A.7.2 RESULTS

1663 1664 1665 1666 1667 1668 1669 1670 1671 Training-free results are shown in Table [12](#page-31-1) and [13.](#page-31-2) MM1.5-Video demonstrates greater capability on Multiple Choice VideoQA, where MM1.5-Video-3B already outperforms state-of-the-art training-free 7B models on all benchmarks. We also find that MM1.5-Video can follow the instruction to precisely output the predicted option; however, most existing methods [\(Li et al., 2024h\)](#page-15-1) use structured answer prompts (*e.g,* "Best Option:(") to guide their models to generate answers in a desirable format. On the other hand, MM1.5-Video achieves only on-par performance compared to SlowFast-LLaVA on the open-ended benchmarks. We hypothesize that this is because our multi-image SFT datasets contain primarily multiple choice tasks, making such a task formulation most similar to the training data.

1672 1673 SFT results are also shown in Table [12](#page-31-1) and [13.](#page-31-2) First, we observe that fine-tuning MM1.5-Video on video datasets can improve its performance on all tasks. Second, on both open-ended and multiple choice benchmarks, our small model, MM1.5-Video-1B, significantly outperforms LLaVAOneVision-

Table 12: Comparison with SOTA models on Open-Ended and Multiple Choice benchmarks.

Third, our 7B model achieves state-of-the-art performance on ActivityNet-QA (*e.g.,* outperforming LLaVAOneVision-7B by 4.3%) and very strong results (mostly runner-up) on other benchmarks by using only public video datasets. We are impressed by the superior results of LLaVAOneVision-7B, especially on long-form video benchmarks such as VideoMME and EgoSchema. We hypothesize this can be due to that (i) it is trained on their re-annotated video datasets with better labeling quality, (ii) it takes more video frames as inputs (*i.e.,* 32 vs. 24), (iii) it uses multiple training stages on joint image and video datasets. We will explore these directions to improve our model in future work. Lastly, MM1.5-Video achieves state-of-the-art performance on the LLaVA-Hound benchmarks, which demonstrates our capability for detailed video understanding.

- **1717 1718**
- **1719** A.8 MM1.5-UI

1720 1721 1722 1723 1724 1725 1726 1727 One of the most promising applications of MLLMs that has recently gained popularity is using them to understand and act on user interfaces (UIs) on behalf or alongside users [\(Hong et al., 2024b;](#page-12-6) [Baechler](#page-10-11) [et al., 2024;](#page-10-11) [You et al., 2024;](#page-20-8) [Li & Li, 2023\)](#page-14-14), which could significantly boost users' productivity and efficiency when interacting with digital devices. This application typically involves providing a model input of: (i) an image of the graphical user interface (GUI) of a device (*i.e.*, phone or computer) screen; and *(ii)* instructions on either knowledge *grounded* on certain areas or the entirety of the screen (*e.g.*, Is this element at <x1,x2,y1,y2> clickable?), or asking it to *refer* to certain areas of the screen that fit the questions' criterion (*e.g.*, Where is the text 'login' on the screen?). Beyond referring and grounding abilities, excelling on UI tasks also requires text-rich image understanding ability to

 Figure 10: Illustration of the UI understanding capability shown in MM1.5-UI. Our single model is able to perform a variety of referring and grounding tasks and establish new state-of-the-arts. Moreover, it can summarize the functions of the UI screen and engage with users through conversations.

 understand text-dense UIs, and background knowledge about typical user interactions on devices, which makes MM1.5 a perfect candidate to be developed into a highly capable UI understanding model.

 Towards this goal, we developed MM1.5-UI, an MM1.5 model variant further fine-tuned specifically on UI data that achieves competitive performance on UI understanding tasks and establishes new state-of-the-art performance in various benchmarks. Figure [10](#page-32-0) illustrates a single MM1.5-UI model's wide range of UI understanding capabilities on an iPhone screenshot. The model can find certain text ("BRIGHTNESS") on the left side (box2), correctly identify the settings icon at the top left (box1), classify a UI element on the right as a checkbox (box0), and maintain a multi-turn conversation about the "Night Shift" function (box3) in the UI.

A.8.1 BENCHMARKS AND METRICS

 We train and evaluate MM1.5-UI on a variety of public and elementary UI understanding tasks used in Ferret-UI [\(You et al., 2024\)](#page-20-8). These tasks are established benchmarks in literature that cover multiple aspects of UI understanding, and allow us to fairly compare MM1.5-UI against prior work:

 • Public Benchmarks include screen2words [\(Wang et al., 2021\)](#page-19-17): a screen-level captioning task; widget captions [\(Li et al., 2020\)](#page-15-17): a widget-level captioning task; and taperception [\(Schoop et al.,](#page-17-17) [2022\)](#page-17-17): predicting the tapability of a certain widget on the UI.

 • Ferret-UI elementary tasks are split into two categories: Grounding (Grd-*) are questions querying for a certain area on the screen, such as finding an icon; and Referring (Ref-*) are questions given a certain area on the screen, such as recognizing text within a screen area (*i.e.*, OCR). Each of these tasks also has an iOS (*-i) and Android (*-A) version, forming four categories of tasks (*e.g.*, Grounding task on Android is Grd-A).

1782 1783 Table 14: Comparison with SOTA models on UI benchmarks. S2W: screen2words, WiC: widget captioning, TaP: taperception. (†) denotes per-task fine-tuning. 1 ep. means 1 epoch model training.

1799 1800 More details of the benchmarks can be found in Appendix [A.10](#page-34-1) and the original Ferret-UI paper [\(You](#page-20-8) [et al., 2024\)](#page-20-8).

1788 1789

1791 1792

1802 1803 A.8.2 RESULTS

1804 1805 1806 1807 1808 MM1.5-UI models are trained by further fine-tuning the final MM1.5 models on the Ferret-UI data mixture [\(You et al., 2024\)](#page-20-8), which includes training data corresponding to the above elementary UI tasks and additional GPT-4-generated conversations about functionalities and descriptions about the UIs' functionality and layouts. There are 801K samples in total. All models are trained with the same batch size and learning rate as the original MM1.5 model.

1809 1810 1811 1812 1813 Comparison with Prior Art. Results are summarized in Table [14.](#page-33-0) Our MM1.5-UI models outperform prior best models in nearly all benchmarks except Screen2words. In particular, even our 1B model is able to outperform the Ferret-UI model in its proposed elementary tasks by a wide margin despite being ten times smaller. The performance difference is most significant on iOS tasks at 9.1 points on average. This demonstrates that the abilities learned by MM1.5 are relevant and useful for UI tasks.

1814 1815 1816 1817 1818 1819 1820 1821 1822 When comparing the performance across individual benchmarks, MM1.5-UI demonstrates a clear hierarchy of difficulties among tasks that focus on different types of UI elements, similar to Ferret-UI [\(You et al., 2024\)](#page-20-8). Tasks focused on text are the most challenging, followed by those involving icons, while widget-based tasks are the easiest. This trend holds for both referring and grounding tasks. However, MM1.5-UI shows a notable performance improvement in icon-based tasks, significantly narrowing the gap between icon and widget tasks. Ferret-UI highlighted the importance of resolution for tasks involving smaller elements like icons. The higher resolution and dynamic image splitting used in MM1.5-UI further confirm that resolution is particularly beneficial for enhancing performance in icon-related tasks.

1823 1824 1825 1826 1827 1828 1829 1830 Impact of MM1.5 SFT on UI tasks. To highlight the effectiveness of the MM1.5 SFT mixture on downstream UI tasks (*i.e.*, in MM1.5-UI), we compare the performance of the full MM1.5-UI model with a baseline UI model fine-tuned with UI data on the pre-training checkpoint that MM1.5 was trained on. Both models are trained for one epoch using the Ferret-UI dataset, and their results are presented in Table [14.](#page-33-0) The final MM1.5-UI model, which underwent SFT for general domain, text-rich, and refer&ground tasks, achieves superior UI performance within the same number of training steps. This demonstrates the strong transfer capability of MM1.5 for UI applications and contributes to its performance improvement over prior SOTA models.

1831 1832 1833 1834 1835 Impact of model scaling. We observe overall performance improvements as models scale, though gains in all metrics remain modest, suggesting that larger models may be constrained by factors such as data diversity, image resolution, or overfitting. For instance, in the most challenging OCR tasks, 47.8% of incorrect responses contain the ground truth as a strict substring of the generated response, or vice versa. This suggests the model accurately recognized the text but failed to trim or include the correct amount. Additionally, the performance of the 7B and 30B models appears to have plateaued, **1836 1837** indicating that larger, more diverse datasets and joint SFT of UI and core capabilities could further improve the performance.

1838 1839

1840

A.9 MM1.5 IN-HOUSE MULTI-IMAGE SFT DATA

1841 1842 We generated two sets of in-house SFT data for the multi-image capabilities of our model: cocoinstruct-interleaved and icl-instruct.

1843 1844 1845 1846 1847 Coco-instruct-interleaved was generated using an LLaVa-style approach using our text-only LLM. We input COCO image captions for two images, along with a prompt requiring the LLM to generate a conversation between a user and an assistant, with the two images inserted in context. This dataset helps our model learn conversational multi-image capabilities. An example from this dataset is shown below. This dataset contains ~2k examples, with 2 images per example.

- **1848 1849 1850** User: <image 1> What do you see in the following picture? Assistant: I see an open beige toilet with a monitoring device attached to the
- **1851** seat. The device appears to be displaying various metrics, such as temperature and pressure, and it is likely used for medical purposes.
- **1852** User: \langle image 2> What about this picture?
- **1853 1854 1855** Assistant: I see a row of parking meters sitting next to each other near a street. The meters are typical of those used to enforce parking regulations in many cities.
- User: What is the difference between the two pictures?
- **1856 1857 1858 1859** Assistant: The first picture depicts a toilet with a monitoring device, while the second picture shows a row of parking meters. These are two very different objects in different settings. The first picture is likely used for medical purposes, while the second picture is used to regulate parking in cities.
- **1860 1861 1862 1863 1864** Icl-instruct was generated manually to help the model retain in-context learning abilities from pretraining along with more nuanced in-context learning tasks that require multi-step reasoning from the model. This dataset contains different varieties of in-context learning tasks, some of which are similar to those found in the VL-ICL benchmark [\(Zong et al., 2024\)](#page-21-0). We found that including this dataset, which contains ~500 examples, greatly boosts the models' in-context learning performance.
- **1865 1866**

1867 A.10 MM1.5-UI BENCHMARK DETAILS

1868 The public benchmark tasks and metrics for evaluating MM1.5-UI are:

- **1869 1870 1871** • Screen2words is a captioning task where each complete screen is paired with 5 ground-truth high-level summaries under ten words. The generated summaries' quality is measured by CIDEr score between the ground-truth and generated summaries.
- **1872 1873 1874** • Widget Captioning is a captioning task where a certain screen area that corresponds to a widget (*e.g.*, button, list item) is paired with 3 ground-truth captions. The generated summaries' quality is measured by CIDEr score similar to Screen2words.
- **1875 1876 1877 1878** • Taperception is a binary classification task where a certain screen area that correspond to a widget (*e.g.*, button, list item) is paired with a ground-truth binary label of whether the screen area is 'tappable' (*i.e.*, clickable by users). The generated labels' quality is measured by F1 score.
- **1879 1880** The Ferret-UI Elementary task benchmarks used to evaluate MM1.5-UI, organized by capability categories, are:
- **1881 1882 1883 1884 1885** • Ferret-UI Grounding (Grd-i/A) is a set of three grounding-based UI tasks introduced in Ferret-UI [\(You et al., 2024\)](#page-20-8). These tasks query for certain areas of screens that meet certain criteria. They include finding a widget given a text description, finding an icon given the class of the icon, and finding a text location on screen. The expected response from the model is a bounding box, and the quality of the bounding box is measured by Recall with $IoU > 0.5$.
- **1886 1887 1888 1889** • Ferret-UI Referring (Ref-i/A) is a set of three referring-based UI tasks introduced in Ferret-UI [\(You et al., 2024\)](#page-20-8). These tasks query about knowledge or characteristics that correspond to certain areas of the screens. They include classifying the type of widgets in the given areas, recognizing the type of icons in the given areas, and recognizing texts in the given areas. The quality of the responses is measured by exact match accuracies.

1902 1903 1904 Figure 11: Illustration of image grid selection used in dynamic image splitting for high-resolution image encoding. (Left) If the grid can cover the full image without scaling down, we choose the grid that minimizes padding. (Right) Otherwise, we choose the grid that minimizes the resolution loss due to scaling down.

1906 1907 1908 Each of these two sets Ferret-UI tasks further have two variants with screenshots from two types of operating systems (iOS/Android), of which Android tasks are denoted as -A (*e.g.*, Grd-A), and iPhone tasks as -i, which results in 12 tasks in total.

1910 A.11 DYNAMIC VS STATIC IMAGE SPLITTING

1912 1913 Detailed ablation study of MM1.5 with different image splitting strategies is shown in Table [15,](#page-35-0) [16,](#page-36-0) [17](#page-36-1) and [18.](#page-37-0) All models are using the final setting except for the image splitting (dynamic vs. static).

1914 1915 1916 Table 15: Comparison of our models when using dynamic vs. static image splitting. We follow our final settings for all models. (S) and (D) indicate static and dynamic splitting, respectively.

A.12 METHODOLOGY FOR RUNNING COMPETITOR MODELS

1936 1937 1938 1939 1940 1941 1942 This section covers the methodology used to report results for Phi-3-Vision [\(Abdin et al., 2024b\)](#page-10-2), LLaVA-OneVision [\(Li et al., 2024c\)](#page-14-0), InternVL2 [\(Chen et al., 2024b\)](#page-11-0) and MiniCPM-V2 [\(Yao et al.,](#page-19-4) [2024b\)](#page-19-4). When available, we reported the results published by the original authors, either in their technical reports or on public leaderboards^{[7](#page-35-1)}. When not available, we implemented inference runners using publicly released checkpoints. Commonly, we followed [\(Li et al., 2024b\)](#page-14-15)'s implementations that we adapted on our own internal fork of lm-eval-harness [\(Gao et al., 2023;](#page-12-1) [McKinzie et al., 2024\)](#page-17-2). To verify the validity of our inference implementations, we ensured we could reproduce previously published results within standard deviation. Below, we share details for each model implementation:

1944 1945 Table 16: Comparison of our models when using dynamic vs. static image splitting. We follow our final settings for all models. (S) and (D) indicate static and dynamic splitting, respectively.

Table 17: Comparison of our models when using dynamic vs. static image splitting. We follow our final settings for all models. (S) and (D) indicate static and dynamic splitting, respectively.

> Phi-3-Vision. We used the public Phi-3-Vision checkpoint^{[8](#page-36-2)} and ran it on our families of benchmarks. For general, text-rich, knowledge and refer&ground benchmarks, when the position of the image is not determined by the task, we prepend the image to the text input following the examples given in the Phi-3-Vision cook book^{[9](#page-36-3)}. For **grounding** benchmarks, we introduced the following prompt: "Question: {question}
>b>Answer this question by listing the requested entities and their bounding boxes. The bounding boxes are formatted as follows: $\langle x1, y1, x2, y2 \rangle$, each value is between 0-{upper_bound}.<n>Answer:". For both referring and grounding, we experimented with a variety of upper bound bounding boxes. Through our experiments, we noticed that an upper box of 1 yielded to

⁹ https://github.com/microsoft/Phi-3CookBook/blob/main/md/03.Inference/Vision_Inference.md#3 comparison-of-multiple-images

1998 1999 Table 18: Comparison of our models when using dynamic vs. static image splitting. We follow our final settings for all models. (S) and (D) indicate static and dynamic splitting, respectively.

2021 2022

2023 2024 2025 better results, in line with the answers produced by Phi-3-Vision. For Flickr30k, we slightly simplified the benchmark and asked the model to ground one entity per prompt, as grounding multiple entities jointly did not lead to satisfactory results.

2026 2027 2028 2029 2030 2031 LLaVA-OneVision. We used the public checkpoint LLaVA-OneVision 7B^{[10](#page-37-1)} and we followed closely the LLaVA documentation^{[11](#page-37-2)}. When not baked directly into the benchmarks, we used the original LlaVA prompts specified in [\(Liu et al., 2023a;](#page-16-1) [Li et al., 2024c\)](#page-14-0) for all families of benchmarks. In particular, for **grounding** benchmarks, we used the prompt introduced in Table 18 of [\(Li et al.,](#page-14-0) [2024c\)](#page-14-0): "Provide the bounding box coordinate of the region this sentence describes". On Flickr30k, we followed the single-entity approach outlined above.

2032 2033 2034 2035 2036 2037 2038 2039 InternVL2. The InternVL2 authors provided already a comprehensive set of benchmarks on general, text-rich, knowledge and refer&ground families^{[12](#page-37-3)}, which we reported first. For the few remaining benchmarks, we used the 2B public checkpoint released. InternVL2 code base relies on both VLMEvalKit [\(Duan et al., 2024\)](#page-11-15) and a custom internal evaluation 13 . We carefully reviewed the logic implemented^{[14](#page-37-5)}, especially regarding the decoding parameters and prompts used. For **grounding**, we used the prompt shared by the authors: "Please provide the bounding box coordinates of the region this sentence describes: <ref>{question}</ref>". On Flickr30k, we followed the single-entity approach outlined above.

2040 2041 2042 2043 MiniCPM-V2. We used the publicly released MiniCPM-V2 2.8B checkpoint^{[15](#page-37-6)}. Similarly to In-ternVL2, MiniCPM-V2 code base relies on both VLMEvalKit and a custom internal implementation^{[16](#page-37-7)}, which we reviewed carefully to reproduce decoding parameters and prompts. For **refer&ground** benchmarks, we noticed that regardless of the prompt used, MiniCPM-V2 could not produce satisfac-

 tory results on RefCOCO and Flickr30 k^{17} k^{17} k^{17} . We decided not to include those results. For **multi-image** and in-context learning benchmarks, we found that MiniCPM-V2 does not accept multiple images as input in its Hugging Face implementation. We acknowledge MiniCPM-V2's authors used a custom image concatenating approach for BLINK^{[18](#page-38-1)}, but we could not reproduce easily the same approach on other benchmarks. We decided to only include the BLINK score reported by the authors^{[19](#page-38-2)}.

 Figure 12: The overview of model architecture. MM1.5 excels at (i) text-rich image understanding with dynamic image splitting, (ii) visual referring and grounding with coordinate tokens, and (iii) multi-image reasoning.

¹⁷Responses commonly produced incomplete bounding boxes, preventing any parsing for a fair evaluation.

 A.13.2 TEXT-RICH IMAGE UNDERSTANDING

A.13.4 MULTI-IMAGE REASONING

 П --------------------------------- n n \Box n n n n **The Second Second** Please identify the most significant actions in the video. What conclusions can be drawn from these actions? The character is seen lying on the bed, holding a black shirt. They then place the black shirt on the bed. The character is seen holding a gray shirt and places it on the bed as well. They then hold a pair of black socks and place them on the bed. The character is seen holding a pair of red socks and places them on the bed. The character is seen holding a pair of black shoes and places them on the bed. <u> El el el el el el el el el e</u>l e **TITLE** mп THE LE Please describe the video in details. In the video, a person is engaged in the act of painting a wedding scene on a canvas. The canvas is propped up on a table, which is cluttered with various art supplies. The person is holding a paintbrush, dipping it into a palette filled with different shades of paint. They are carefully applying the paint to the canvas, bringing the wedding scene to life. The table around the canvas is a testament to the artist's process. It's covered in art supplies - brushes of different sizes and shapes, jars of paint in various colors, and a sketchbook filled with preliminary sketches. The sketchbook, in particular, provides a glimpse into the artist's thought process, with sketches of the wedding scene visible on its pages. The background of the video is a wall adorned with shelves. The shelves are lined with more art supplies, indicating a well-stocked workspace. The overall scene suggests a dedicated artist immersed in their work, bringing a beautiful wedding scene to life on canvas.
