

# Bi-Mamba: Towards Accurate 1-Bit State Space Models

Anonymous authors

Paper under double-blind review

## Abstract

The typical selective state-space model (SSM) of Mamba addresses several limitations of Transformers, such as quadratic computational complexity with sequence length and significant inference-time memory requirements due to the key-value cache. However, the growing size of Mamba models continues to pose training and deployment challenges and raises environmental concerns due to considerable energy consumption. In this work, we introduce **Bi-Mamba**, a scalable and powerful 1-bit Mamba architecture designed for more efficient large language models with multiple sizes across 780M, 1.3B, and 2.7B. **Bi-Mamba** models are trained from scratch on data volume as regular LLM pertaining using an autoregressive distillation loss. Extensive experimental results on language modeling demonstrate that **Bi-Mamba** achieves performance comparable to its full-precision counterparts (e.g., FP16 or BF16) and much better accuracy than post-training-binarization (PTB) Mamba and binarization-aware training (BAT) Transformer baselines, while significantly reducing memory footprint and energy consumption compared to the original Mamba model. Our study pioneers a new linear computational complexity LLM framework under low-bit representation and facilitates future design of specialized hardware tailored for efficient 1-bit Mamba-based LLMs. Our code is provided in *Supplementary Material* and the pre-trained weights are available anonymously at link.

## 1 Introduction

The Selective State-Space Model (SSM) (Gu et al., 2021b; 2022) has recently emerged as a powerful alternative to Transformers Vaswani et al. (2017) in language modeling, demonstrating comparable or superior performance at small to moderate scales. SSMs are characterized by linear scaling in sequence length during training and a constant state size during generation, which significantly reduces computational and memory overhead, making them more efficient in terms of speed and memory usage.

The representative SSM model of Mamba (Gu & Dao, 2024; Dao & Gu, 2024) has a significant advantage when handling long context sequences due to its linear complexity. In contrast, conventional transformers suffer from quadratic complexity as the sequence length increases. This means that for tasks involving large input sequences or extended contexts, Mamba is much more efficient, as its memory and computational requirements scale linearly with the sequence length. In practice, this allows Mamba to process long sequences faster and with lower resource consumption, making it ideal for applications such as long document processing, conversational agents, and any scenario where managing large amounts of contextual information is crucial. On the other hand, transformers require exponentially more resources as the context length increases, which can quickly become a bottleneck in long-context tasks.

Prior works (Devlin et al., 2019; Radford et al., 2019; Touvron et al., 2023; Achiam et al., 2023) on Transformers have been extensively studied for several years, with numerous methods proposed to alleviate their high computational and storage costs, such as pruning (Ma et al., 2023), model quantization Frantar et al. (2023), and KV Cache (Pope et al., 2023; Kwon et al., 2023). Among these methods, quantization has proven to be highly effective Dettmers et al. (2022b). Researchers have successfully quantized transformer models from 16-bit to 8-bit, 4-bit, and even 1-bit representations, often with minimal performance degradation Frantar et al. (2023); Ma et al. (2024c;a).

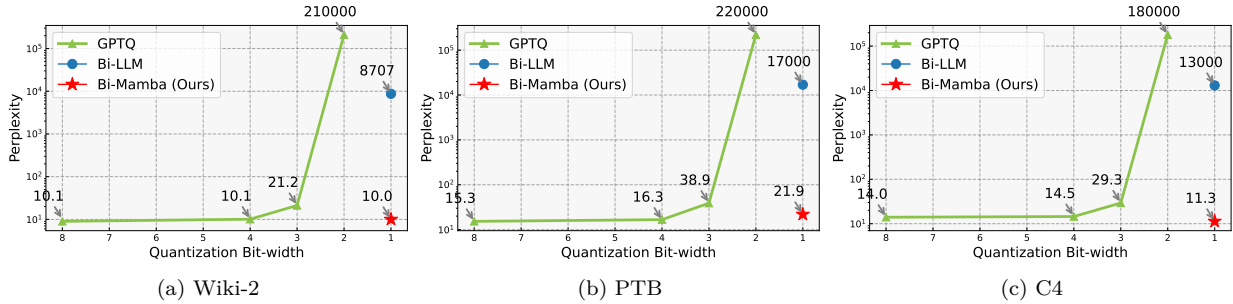

Figure 1: Perplexity comparison of Bi-Mamba, GPTQ and Bi-LLM on Wiki2, PTB and C4 datasets. GPTQ and Bi-LLM show significant performance degradation when the bit is low. Bi-Mamba demonstrates low perplexity in 1 bit and shows similar performance as GPTQ-8bit.

However, there has been little investigation into how SSM models or Mamba behave after low-bit quantization or even binarization. In this paper, we introduce **Bi-Mamba**, a novel approach that applies extreme quantization to SSM models by reducing weights to a binary setting. Through this extreme quantization, we demonstrate that SSM models can be effectively binarized for both training and inference, maintaining high performance while significantly reducing memory footprint and energy consumption.

Our work pioneers a new framework for 1-bit representation in linear computational complexity models, potentially facilitating the development of specialized hardware tailored for fully low-bit SSM-based language models. We provide comprehensive experiments showing that **Bi-Mamba** achieves competitive performance comparing to full-precision counterpart large language models (LLMs), thereby establishing the feasibility and benefits of binarizing SSM models. To further understand the behaviors of binarization on Mambas, we conducted extensive empirical studies to analyze the distribution of pre-trained and binarized weights in Mambas. The results of this study are detailed in Section 4 and Appendix A, leading to two key observations:

- As shown in Figure 2, post-training-binarization methods like BiLLM (Huang et al., 2024) and PB-LLM (Shang et al., 2023) typically tend to shift the distribution of weights on Mamba after binarization, resulting in a misaligned distribution to the optimal binary weights. Our binarization-aware training, however, ensures that the binarized weights remain close to the original weight distribution, preserving the largest capability in weight representation binarization.
- Based on our empirical experiments, applying existing LLM post-binarization methods (Frantar et al., 2023; Huang et al., 2024), even when retaining salient weights, often severely degrades the performance of the Mamba model. Without accounting for salient weights, binarization-aware training appears to be the only feasible solution for effectively binarizing models like Mamba while preserving competitive performance.

Our contributions in this paper are as follows: (1) This is the first work to successfully binarize the Mamba architecture to 1-bit from scratch while maintaining strong performance. (2) We explore the potential parameter space for binarization in Mamba, offering valuable insights for future research. (3) The **Bi-Mamba** model pretrained by our method can serve as a robust base model for downstream tasks in resource-limited scenarios and can be easily adapted for other NLP applications.<sup>1</sup>

## 2 Related Work

**Post-Training Quantization.** Due to their large parameter count, LLMs (Brown et al., 2020; OpenAI, 2023; Touvron et al., 2023) are resource intensive to run. Therefore they are often quantized to low bits representations during inference. This type of quantization is typically called post-training quantization (PTQ) (Dettmers et al., 2022a; Xiao et al., 2023; Wei et al., 2022; Frantar et al., 2023; Yao et al., 2022;

<sup>1</sup>We will make all our models, code, and training datasets fully available, we aim to support further research in this direction and encourage the exploration of binarized SSM models for more efficient large language models.

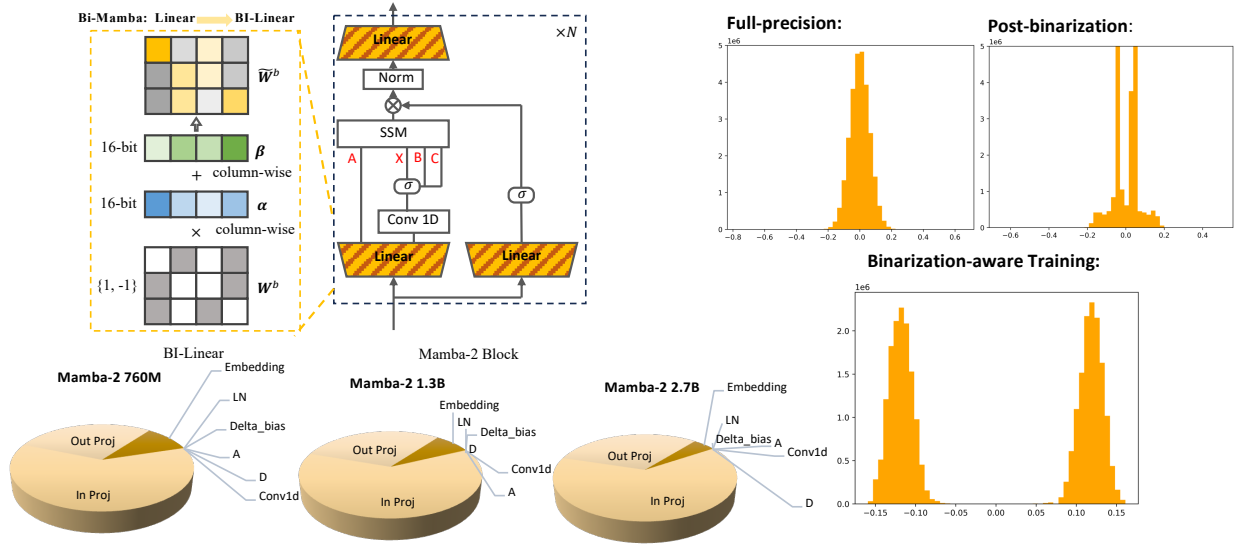

Figure 2: Illustration of the Bi-Mamba framework. Our Bi-Mamba binarizes both input and output projection matrices. Compared with the post-binarization method (Bi-LLM), our binarization-aware training method (Bi-Mamba) generates a more similar weight distribution (after scaling) on each part.

Xiao et al., 2023; Lin et al., 2024), where the quantization operation is applied to the pretrained models. Post-training quantization methods of LLMs are typically based on the empirical observations that a small set of salient features in pretrained Transformers have significantly large magnitudes, and quantization of these features needs to be extra careful (Xiao et al., 2023; Lin et al., 2023). PTQ methods have led to near lossless accuracy drop for INT8 weights and activations quantization, and INT4 weight-only quantization. While many works (Huang et al., 2024; Egiazarian et al., 2024; Shao et al., 2023; Chee et al., 2023; Tseng et al., 2024) have been focused on pushing post-training weight quantization below 4 bits, they often leads to drastic drop of model performance.

**Quantization-Aware Training.** Different from post-training quantization, quantization-aware training (QAT) aims to learn the quantized models during training. In the LLM era, QAT is less investigated as compared to PTQ because LLMs typically require huge amounts of compute resources to train. Li et al. (2023b) propose a method to adopt LoRA fine-tuning during QAT, making the quantization procedure resource efficient. However, these methods still require the pretrained weights to initialize the student LLMs. Wortsman et al. (2023) propose a method to stabilize the training of low-bit large vision-language models from random initializations. Most recently, Ma et al. (2024c) trained LLMs with tenary weights from random initializations, achieving non-trivial performance. Ma et al. (2024a) further proposed a distillation based method to pretrain binarized LLMs from scratch.

**State-Space Models.** While LLMs are often built with Transformers (Vaswani et al., 2017), their self-attention operations suffer from quadratic time complexity. This makes Transformers inefficient to run on long sequences. Therefore there have been many research efforts aiming at addressing the efficiency issue (Peng et al., 2023; Beck et al., 2024; Katharopoulos et al., 2020; De et al., 2024). Among these efforts, SSMs (Gu & Dao, 2024; Dao & Gu, 2024; Gu et al., 2021a) are a type of recurrent neural networks. The latest advanced SSMs like Mamba (Gu & Dao, 2024) and Mamba-2 (Dao & Gu, 2024) have demonstrated comparable performance to Transformers, while having linear complexity with respect to the sequence length. Despite their promising capabilities, how to effectively quantize this architecture has rarely been investigated. Concurrent to our work, Pierro & Abreu (2024) have looked at post-training quantization of Mamba.

### 3 Approach

#### 3.1 Preliminary: Mamba Series

Mamba belongs to a class of models known as State Space Models (SSMs), which is able to offer performance and scaling laws comparable to the Transformer while remaining practical at extremely long sequence lengths

Model Size	Embedding	LN	$\Delta_{bias}$	A	D	Conv1d	In Proj.	Out Proj.
Mamba-2 760M	9.901	0.029	0.0003	0.0003	0.0003	0.102	60.936	29.031
Mamba-2 1.3B	7.664	0.022	0.0002	0.0002	0.0002	0.078	62.270	29.964
Mamba-2 2.7B	4.763	0.018	0.0002	0.0002	0.0002	0.064	64.115	31.039

Table 1: Proportional distribution of parameters across different modules in Mamba-2. Input and output matrices take up the majority of the parameters in Mamba-2 models, around 90% and more.

(e.g., one million tokens). It achieves this extended context by eliminating “quadratic bottleneck” present in the attention mechanism. The vanilla structured state space sequence models (S4) transform a 1-dimensional sequence  $x \in R^T$  into another sequence  $y \in R^T$  by utilizing an latent state  $h \in R^{T,N}$  as follows:

$$\begin{aligned} h_t &= Ah_{t-1} + Bx_t \\ y_t &= Ch_t + Dx_t \end{aligned} \quad (1)$$

where  $A \in R^{N,N}$ ,  $B \in R^{N,1}$ ,  $C \in R^{1,N}$ ,  $D \in R$ .  $h_{t-1}$  is the hidden state,  $x_t$  is the input, the observation that the model gets each time.  $h_t$  then represents the derivative of the hidden state, i.e. how the state is evolving.

Since the parameters in Equation 1 are constant through time, this model is linear time-invariant (LTI). The LTI model gives equal attention to all elements when processing sequences, which prevents the model from effectively understanding natural language. To address this, Mamba improved it to the Selective State Space Model, where  $B$  and  $C$  are obtained through a linear projection of  $x_t$ . Meanwhile, the above equation applies to dynamic systems with continuous input and output signals. So, it needs to do discretization when dealing with text sequences:

$$\begin{aligned} \bar{A} &= \exp(\Delta A) \\ \bar{B} &= \exp(\Delta A)^{-1}(\exp(\Delta A) - I) \cdot \Delta B \end{aligned} \quad (2)$$

where,  $\Delta$  is related to  $x_t$  and a learnable parameter  $\Delta_{bias}$ . Then, the calculating process of selective SSM is as follows:

$$\begin{aligned} h_t &= \bar{A}h_{t-1} + \bar{B}x_t \\ y_t &= Ch_t + Dx_t \end{aligned} \quad (3)$$

Centered around selective SSM, combined with linear projection for input and output along with layer normalization, this forms the basic block for Mamba.

Compared to Mamba, Mamba-2 further replaces selective SSM with the state space duality (SSD). In SSD,  $A$  is simplified as scalar-times-identity structure, and SSD uses a larger head dimension which is 1 in Mamba. Meanwhile, Mamba-2 block also introduces simplifications, such as removing sequential linear projections in Mamba block, to facilitate parallel training. The basic structure of Mamba-2 is shown in Figure 2.

### 3.2 Bi-Mamba

**Binarization Space in Mamba.** To begin with, we need to identify what weight matrices can be binarized in Mamba architecture. We use the latest Mamba-2 Dao & Gu (2024) as our base architecture. According to the description above, we can interpret the SSD matrices of  $A$ ,  $B$ ,  $C$ ,  $D$ , and  $\Delta_{bias}$  more intuitively, as well as other layers including *embedding*, *layer normalization (LN)*, *Conv-1d*, *inner linear projection*, *out linear projection* in Mamba-2 to better understand the effect after binarization, so that to determine the binarization space. Briefly,  $A$  is the transition state matrix, representing how the current state transitions to the next state. It answers the question of *how should the model gradually forget the less relevant parts of the state over time?*  $B$  maps the new input to the state, addressing the point of *which parts of the new input should the model retain?*  $C$  maps the state to the output of the SSM, asking that *how can the model utilize the current state to make an accurate next prediction?*  $D$  shows how the new input directly influences the output, acting as a modified skip connection and asking *how can the model incorporate the new input into the prediction?*

Considering our base architecture Mamba-2, we present the specific parameters proportion for different layers across different sizes as shown in Figure 2 and Table 1<sup>2</sup>. It is observed that, in Mamba-2, the vast majority of the model’s parameters are in the linear modules, excluding the causal head. For instance, in Mamba-2-2.7B, these parameters account for 95.2% of the entire model. Additionally, the embedding module shares parameters with the causal head. Binarizing the embedding significantly diminishes its capability to represent token semantics, thereby reducing model performance. Therefore, in our **Bi-Mamba**, we only binarize the parameters in the linear modules (excluding the causal head). This strategy aims to maintain a high compression ratio of 90% while still allowing the binarized model to perform effectively.

**Simple Learnable Scaling Factors for Better Capability.** To binarize Mamba, we replace the original linear modules with the FBI-Linear module introduced by FBI-LLM (Ma et al., 2024a). Specifically, the FBI-Linear module primarily consists of two parts: a matrix  $\mathbf{W}^b \in \mathbb{R}^{m \times n}$  made up solely of  $\{1, -1\}$  and high-precision scale factors  $\alpha \in \mathbb{R}^n$  and  $\beta \in \mathbb{R}^n$ . The inference process of FBI-Linear is as follows:

$$\mathbf{y} = \widetilde{\mathbf{W}}^b \mathbf{x} \quad (4)$$

where  $\widetilde{\mathbf{W}}^b$  is derived by performing column-wise multiplication with  $\alpha$  and addition with  $\beta$  respectively:

$$\widetilde{\mathbf{W}}_{:,i}^b = \alpha_i \mathbf{W}_{:,i}^b + \beta_i \quad (5)$$

where  $\alpha_i$  and  $\beta_i$  are the learnable scaling and shifting factors at  $i$ -th layer.

**Objective of Training.** Our training objective is a cross-entropy loss between the outputs of the target student model and the pretrained teacher model at each step of the autoregressive scheme for next-token prediction. This can be expressed as:

$$\mathcal{L}_{\text{Bi-Mamba}} = -\frac{1}{n} \sum_k^n \mathbf{p}^T(x^{k+1}) \cdot \log \mathbf{p}^S(x^{k+1}) \quad (6)$$

where  $n$  is the number of input tokens. Here,  $\mathbf{p}^T(x^{k+1})$  represents the token distribution over the vocabulary at the  $k$ -th step predicted by the teacher model, and  $\mathbf{p}^S(x^{k+1})$  is the corresponding predicted distribution by the student model.

**Overall Design of Bi-Mamba.** During binarization-aware training of autoregressive distillation (Ma et al., 2024a), we compute the cross-entropy between the output probability distributions of a high-precision pre-trained model and our target **Bi-Mamba** model. In this process,  $\alpha$  and  $\beta$  are learnable parameters, while  $\mathbf{W}^b$  is derived using the  $\text{sign}(\cdot)$  function from a learnable high-precision matrix  $\mathbf{W}^f \in \mathbb{R}^{m \times n}$ . Since the  $\text{sign}(\cdot)$  function is non-differentiable, we use the Straight Through Estimator (STE) (Bengio et al., 2013) as prior studies (Rastegari et al., 2016; Alizadeh et al., 2019) in BNNs to approximate the gradients of the input variables, enabling the continuation of backward propagation.

## 4 Experiments

In our experiments, we solely binarize the parameters in the most linear modules, while keeping other model parameters and activation at original precision. Notably, we do not strictly represent the binarized parameters with 1-bit, instead, we use high-precision values to simulate the binarized parameters. We train **Bi-Mamba** on different scales and evaluate their performance across multiple tasks.

### 4.1 Setup

**Training Dataset.** Following FBI-LLM, we train **Bi-Mamba** with the Amber dataset (Liu et al., 2023) which contains a total 1.26 Trillion tokens from RefinedWeb (Penedo et al., 2023), StarCoder (Li et al., 2023a), and RedPajama-v1 (Computer, 2023). The data is partitioned into 360 chunks, each comprising approximately 3.5B tokens on average.

<sup>2</sup>Since  $B$  and  $C$  are derived from the linear projection of each layer’s inputs, and the language model head is tied to the embedding layer, these modules are ignored in our design.

**Training details.** We train Bi-Mamba on different scales with Mamba-2 architecture. Specifically, we binarize input projection and output projection matrices in 780M, 1.3B and 2.7B Mamba-2 models. We use LLaMA2-7B as the teacher model for all Bi-Mambas to calculate autoregressive distillation loss. Therefore, all Bi-Mambas we trained have the same vocabulary and tokenizer as LLaMA2. We train models until convergence with  $32 \times$  NVIDIA A100 GPUs in total and maintain BF16 precision while training. For configuring different sizes of Bi-Mamba, the details can be found at Table 2. We follow the same architectures as the original Mamba-2 models and apply binarization on both input and output projection matrices. The training process uses the Adam optimizer with parameters  $\beta_1 = 0.9$  and  $\beta_2 = 0.95$ . The initial learning rate is set at  $2.5e - 4$  and follows a cosine schedule, decreasing to  $2.5e - 5$  over 2,000 warm-up steps. Gradient clipping is set at 1.0. We train Bi-Mamba 780M, 1.3B, 2.7B with 30 data chunks, which are 105B tokens.

	Bi-Mamba 780M	Bi-Mamba 1.3B	Bi-Mamba 2.7B
d_model	1536	2,048	2,560
n_layer	48	48	64
vocabulary size	32,000	32,000	32,000
learning rate	$2.5e-4$	$2.5e-4$	$2.5e-4$
batch size (token)	0.5M	0.5M	0.5M
teacher model	LLaMA2-7B	LLaMA2-7B	LLaMA2-7B

Table 2: The configuration and training details for Bi-Mamba.

**Evaluation Metrics.** We evaluate the models based on their zero-shot performance in downstream tasks including BoolQ (Clark et al., 2019), PIQA (Bisk et al., 2020), HellaSwag (Zellers et al., 2019), Winogrande (Sakaguchi et al., 2021), ARC (Clark et al., 2018), and OpenbookQA (Mihaylov et al., 2018). We also evaluate Bi-Mamba and other baselines on HumanEval and GSM8k datasets. All downstream evaluations are done with *lm-evaluation-harness* package (Gao et al., 2024). We also use perplexity on Wikitext2 (Merity et al., 2016), PTB (Marcus et al., 1993), C4 (Raffel et al., 2020) dataset as the evaluation metric. Perplexity measures how well a probability model predicts a token, quantitatively measuring the model’s generation power.

**Baselines.** We compare our work with quantization and binarization methods, namely GPTQ (Frantar et al., 2023), SqueezeLLM (Kim et al., 2023), AQLM (Egiazarian et al., 2024) and Bi-LLM (Huang et al., 2024). GPTQ, SqueezeLLM and AQLM are post-training quantization methods while Bi-LLM is a post-training binarization method. We apply the official implementation of GPTQ and SqueezeLLM and quantize the Mamba-2 models into 3 and 2 bits, respectively. For AQLM, we use their official implementation to quantize the 780M, 1.3B and 2.7B models into 2.04bit, 1.92bit and 2.09bit. For Bi-LLM, we also utilize their official implementation and binarize Mamba-2 models. Moreover, we add quantization-aware training methods, OneBit (Xu et al., 2024) and BitNet-1.58bit (Ma et al., 2024b) for comparison. For BitNet, we report the results in the original paper for comparison while for OneBit, since they only released the official weights of 7B, we only add the results of 7B models. We also add the comparison with FBI-LLM (Ma et al., 2024a), which is a transformer-based binary model. We report the results of FBI-LLM 1.3B model from their paper. Furthermore, we include results from open-source full-precision transformer-based models of various sizes, such as OPT (Zhang et al., 2022), and TinyLLaMA (Zhang et al., 2024), as references.

## 4.2 Main Results

Table 3<sup>3</sup> presents the comparison of our Bi-Mamba model against various baselines on downstream tasks and perplexity on Wiki2, PTB, and C4 datasets. These evaluations provide insight into model generalization capabilities without further task-specific fine-tuning. The visualization of performance comparison is shown in Figure 3. The performance on HumanEval and GSM8k is present in Table 4.

<sup>3</sup>“M” indicating Mamba-2 (Dao & Gu, 2024) and “T” indicating Transformer (Vaswani et al., 2017). *HS*, *WG*, and *OBQA* are abbreviations for HellaSwag, Winogrande, and OpenbookQA, respectively.

Table 3: Performance comparison with baselines on downstream tasks and perplexity. Here, *Model* represents the architecture of the quantized model. We divide the table into three blocks based on model size. Our Bi-Mamba achieves lower perplexity than Bi-LLM and GPTQ on Wiki2, PTB and C4 datasets, as well as the best average performance on downstream tasks compared with GPTQ-2bit and Bi-LLM.

For the 780M Mamba-2 model, Bi-Mamba demonstrates an average downstream performance of 45.3, outperforming GPTQ-3bit and Bi-LLM, which achieve 42.6 and 38.1, respectively. In perplexity assessments, Bi-Mamba reports scores of 13.4, 32.4, and 14.5 on Wiki2, PTB, and C4, respectively, with the baseline models exhibiting up to  $10\times$  higher perplexity. SqueezeLLM and AQLM achieve better performance on both downstream tasks and perplexity compared with GPTQ while they are still surpassed by Bi-Mamba 780M model. Moreover, Bi-Mamba 780M surpasses the binarization-aware training method, BitNet on the zero-shot performance on downstream tasks. BitNet obtains 44.3 scores on average while Bi-Mamba 780M achieves 45.3 scores.

For the 1.3B model, Bi-Mamba achieves a notable downstream accuracy of 48.4 on average, surpassing GPTQ-2bit’s 35.3, SqueezeLLM-2bit’s 46.5, AQLM’s 39.6 and Bi-LLM’s 36.2. This performance indicates Bi-Mamba’s enhanced generalization across a wider range of tasks at this model size. Additionally, Bi-Mamba demonstrates substantially improved perplexity, registering scores of 13.2, 30.8, and 14.0 on Wiki2, PTB, and C4 datasets, respectively. In comparison, GPTQ-2bit and Bi-LLM present considerably higher perplexity values, underscoring the efficiency of Bi-Mamba’s binarization in maintaining linguistic coherence. Moreover, Bi-Mamba 1.3B model beats the training-based method, BitNet and FBI-LLM, which obtains 45.4, 46.3 scores on average on the downstream tasks.

For the 2.7B model, Bi-Mamba further extends its lead, achieving an average downstream accuracy of 50.6, compared to 35.8 for GPTQ-2bit, 35.5 for SqueezeLLM-2bit, 45.2 for AQLM-2.09bit, and 38.5 for Bi-LLM. Notably, Bi-Mamba maintains low perplexity across all datasets, with scores of 10.0, 21.9, and 11.3 on Wiki2, PTB, and C4, respectively. These results highlight Bi-Mamba’s ability to retain high-level performance in both task accuracy and linguistic fluency as model complexity scales up. Similarly, Bi-Mamba 2.7B model outperforms all training-based methods including OneBit and BitNet. OneBit only obtains 49.5 scores on average with 6.7B parameters and BitNet gains 50.2 scores with 3.0B parameters. The results demonstrate the effectiveness of Bi-Mamba. In summary, Bi-Mamba consistently demonstrates superior zero-

Figure 3: Visualization of results comparison on Mamba-2 in the scale of 2.7B, 1.3B and 780M.

shot performance and perplexity reduction across model sizes, substantiating its robustness and versatility compared to GPTQ and Bi-LLM, particularly in larger, more complex models.

## 5 Analysis

### 5.1 Training Result Dynamics

In this section, we discuss the performance of Bi-Mamba as the training progresses with different training costs/budgets. The main results are shown in Figure 4. We provide the downstream performance and perplexity curve along different training costs on the Mamba-2-780M model. More results on 2.7B and 1.3B Mamba-2 models can be found in the Appendix A.1. From the figure, we can observe that the perplexity decreases quickly at the beginning of training and gradually converges to the full-precision perplexity. The perplexity of Bi-Mamba on the wiki2 and C4 datasets is more stable than the perplexity on the PTB dataset. Notably, on the C4 dataset, the final perplexity of Bi-Mamba is even lower than the full-precision model, highlighting the superior performance of Bi-Mamba. Interestingly, early in training, our Bi-Mamba model surpasses GPTQ-3bit on the perplexity, demonstrating the effectiveness of binarization-aware training. Since the perplexity of GPTQ-2bit and BiLLM is extremely high on all datasets, we omit them in the figure and

Figure 4: Downstream performance and perplexity curve of Bi-Mamba with different training costs.

refer to Table 3 for detailed results of GPTQ-2bit and BiLLM. Moving to the downstream task evaluation, we first observe the catastrophic performance degradation of the binarized models, whose performance is even lower than the random results on many benchmarks such as the results on ARC-E and ARC-C. This indicates that directly applying the naive binarization method destroys the ability of the full-precision model. However, after binarization-aware training, the model recovers the performance on all benchmarks and finally outperforms all baselines including GPTQ-3bit, GPT-2bit and Bi-LLM. This underscores the importance of binarization-aware training in achieving competitive results.

## 5.2 Binarization Space

In this section, we explore the binarization space of Mamba models and discuss the effect of binarizing each part. We conduct experiments that binarize the `In_Proj` and binarize both `In_Proj` and `Out_Proj`. The binarized models are trained with the same data. The results are shown in Table 5. Partial and full binarization are compared with the full-precision Mamba model on perplexity and downstream tasks. First, the results in the table show that partial binarization generally retains higher zero-shot accuracy compared to full binarization. However, the performance gap between the partial and full binarized models is not significant. For instance, in the Mamba-2-2.7B model, partial binarization achieves an average accuracy of 53.1, while full binarization reduces this to 50.4. Across all model sizes, partial-binarized **Bi-Mamba** consistently outperforms full-binarized **Bi-Mamba** on most benchmarks, though shows minor performance degradation compared with full-precision models. It also suggests that fully binarization remains highly competitive and does not substantially lag. In terms of perplexity, the fully binarized model also performs comparably to the partial model. For example, in the Mamba-2-780M model, the C4 dataset perplexity for full-binarized **Bi-Mamba** (Fully) is 15.0, compared to 14.4 for partial-binarized **Bi-Mamba**, demonstrating that full binarization does not impose a significant perplexity increase. These findings highlight that the fully binarized model can maintain competitive performance with the partial binarization model, particularly in terms of perplexity, while still benefiting from greater storage and computational efficiency.

Model	Zero-shot Acc. $\uparrow$								Perplexity $\downarrow$		
	BoolQ	PIQA	HS	WG	ARC-e	ARC-c	OBQA	Avg.	Wiki2	PTB	C4
Mamba-2-780M	61.5	71.8	54.9	60.2	54.3	28.5	36.2	52.5	11.8	20.0	16.5

Mamba-2-1.3B	64.3	73.7	59.9	61.0	60.4	33.1	37.8	55.8	10.4	17.7	14.8
Bi-Mamba (In_Proj)	62.1	71.7	50.4	53.8	49.5	26.8	33.0	49.6	10.7	26.0	12.0
Bi-Mamba (Fully)	60.0	68.8	47.3	55.9	48.0	26.3	32.2	48.4	11.7	29.9	12.9
Mamba-2-2.7B	70.7	76.3	66.6	63.9	64.8	36.3	38.8	59.6	9.1	15.3	13.3
Bi-Mamba (In_Proj)	62.4	74.6	58.9	57.1	54.0	29.4	35.4	53.1	9.1	19.5	10.5
Bi-Mamba (Fully)	58.0	72.5	54.3	56.1	51.4	29.1	32.6	50.6	10.0	21.9	11.3

Table 5: Performance comparison of partial-binarization and fully-binarization on perplexity and downstream tasks. The results show that the performance gap between partial-binarization and fully-binarization is not significant, indicating that the fully binarized model can maintain competitive performance with the partial binarization model.

Model	Tokens	GPU Hours	Zero-shot Acc. $\uparrow$								Perplexity $\downarrow$		
			BoolQ	PIQA	HS	WG	ARC-e	ARC-c	OBQA	Avg.	Wiki2	PTB	C4
Mamba-2 (130M, 16-bit)	300B	1180	55.1	64.0	35.3	52.6	47.4	24.1	30.6	44.2	20.0	35.1	25.2
Mamba-2 (370M, 16-bit)	300B	2360	54.0	69.2	46.9	55.4	48.7	26.7	32.4	47.6	14.1	24.2	19.0
Bi-Mamba (780M, 1-bit)	105B	4640	58.5	68.0	41.6	52.0	42.4	24.3	30.6	45.3	13.4	32.4	14.5

Bi-Mamba (2.7B, 1-bit)	105B	7822	58.0	72.5	54.3	56.1	51.4	29.1	32.6	50.6	10.0	21.9	11.3

Table 6: The performance comparison of Bi-Mamba and a pretrained model in small size. All Bi-Mamba models are better than Mamba-2-130M 16-bit model, which is equivalent to a 2.0B model in 1-bit. Moreover, Bi-Mamba 1.3B and 2.7B models achieve higher performance than Mamba-370M 16-bit model, which is equivalent to a 5.9B model in 1-bit, demonstrating the effectiveness of quantization-aware training instead of training a small model directly. The GPU hours are evaluated on A100 80G.

### 5.3 Comparison with Full Precision Small Models

Instead of binarization, one can train small models with full precision from scratch. We add the performance comparison of Bi-Mamba and small models pretrained with full precision, as shown in Table 6. We utilize the official pretrained weight from Mamba2 including models with 130M and 370M parameters pretrained with 300B tokens. 130M and 370M models in 16 bits are equivalent to 2.0B and 5.9B models in 1 bit, respectively. From the table, all Bi-Mamba models including 780M, 1.3B and 2.7B with only 105B token training are better than the 130M models with full precision on average performance. Specifically, Mamba-2 130M obtains 44.2 of accuracy on downstream tasks, and 20.0, 35.1, 25.2 of perplexity on Wiki, PTB and C4 datasets while the smallest model of Bi-Mamba with 780M parameters achieves 45.3 of accuracy on all downstream tasks and 13.4, 32.4 and 14.5 on Wiki, PTB and C4 datasets. Moreover, Bi-Mamba 1.3B and 2.7B models achieves higher average performance than full-precision 370M Mamba-2 model. Full-precision Mamba-2 370M gains 48.4 on average on downstream tasks. Bi-Mamba 1.3B beats the 370M Mamba-2 model with 48.4 of accuracy on downstream task. The results indicate that binarization with post-training is better than training a full-precision small model from scratch.

### 5.4 Storage Efficiency

Bi-Mamba is trained with full precision but can be saved as binary values in storage and inference. During training, we use *Sign*( $\cdot$ ) function to obtain the binarized weights. Model binarization can significantly reduce the storage requirement in the disk. Following Bi-LLM (Huang et al., 2024), we provide the theoretical storage requirement for our Bi-Mamba in different model sizes compared with full-precision models, as shown in Table 7. For each parameter size, the storage requirements for the original full-precision Mamba-2 model are substantially larger than those for the binarized Bi-Mamba including partial and full binarization. Specifically,

Model	Model Param.	Storage Size	Compress Ratio
Mamba-2	780M	1.45GB	-
Bi-Mamba (InProj)	780M	0.63GB	56.5%
Bi-Mamba (Full)	780M	0.22GB	84.8%
Mamba-2	1.3B	2.50GB	-
Bi-Mamba (InProj)	1.3B	1.01GB	59.6%
Bi-Mamba (Full)	1.3B	0.33GB	86.8%
Mamba-2	2.7B	5.03GB	-
Bi-Mamba (InProj)	2.7B	2.01GB	60.0%
Bi-Mamba (Full)	2.7B	0.55GB	89.0%

Table 7: Storage efficiency Bi-Mamba. Compared with partial binarization, full binarization can reduce the storage size significantly in all scale.

Model	Model Param.	Memory	Token/s	Energy/Infer.
Mamba-2-16bit	2.7B	5.03GB	24.59 $\pm$ 2.26	0.744J
Bi-Mamba (Ternary)	2.7B	1.04GB	62.73 $\pm$ 0.33	0.046J

Table 8: Resource consumption analysis of Bi-Mamba including memory, throughput and energy consumption. Bi-Mamba will reduce the energy and memory consumption significantly by more than  $5\times$ .

fully-binarized Bi-Mamba demonstrates the highest compression ratio, achieving reductions of more than 80%. In contrast, partial-binarized Bi-Mamba provides relatively moderate compression, ranging from 55% to 60%. This analysis highlights the efficiency of fully-binarization in significantly reducing storage requirements while maintaining the model parameter count, making it a highly storage-efficient alternative for large models.

## 5.5 Resource Consumption Analysis

We present the resource analysis of Bi-Mamba, as shown in Table 8. We deploy our Bi-Mamba on the CPU of Mac M4 Pro Chips with Llama.cpp framework<sup>4</sup>. The throughput is measured on text generation with batch size 128. At this moment, we use the ternary computation kernel to conduct the inference. We will release the binary and GPU-support kernel in the future. For the energy computation, we follow Touvron et al. (2023); Desislavov et al. (2021) to compute the energy cost for each inference on A100 40G PCIe GPU, which generally consumes 300W and provides 312 TFLOPS of computation. Specifically, we compute the estimated energy required for generating a single next-token prediction with a sequence length of 128 and batch size of 1. The memory requirements for each model are evaluated with 2048 tokens and 128 batch size. Notably, Bi-Mamba reduces the memory and energy consumption more than  $5\times$ , while increases the throughput of inference to  $2.55\times$ , from 24.59 to 62.73. These improvements in resource efficiency highlight Bi-Mamba’s potential to significantly reduce computational costs in practice.

## 5.6 Weight Distribution

We visualized the weight distributions of different modules in Mamba-2 (Orange histograms) and Bi-Mamba (Blue histograms), as shown in Figure 5. We visualize the weight parameter distributions of different modules in the first (1st), mid (24th) and final (48th) layers of the corresponding 780M models. The input and output projection matrices are the values after re-scaling. Each pair of histograms compares how Bi-Mamba modifies the distribution of weights in different modules, no matter whether the module is binarized or not, illustrating the impact of Bi-Mamba on each module.

Specifically, in the first layer, the weight distribution of the original Mamba-2 such as *Conv1d.weight*, and *D* are tightly concentrated, indicating the strong focus on specific values. In contrast, the weight distribution in Bi-Mamba in the first layer is much divergent with additional peaks in the histograms such as in *A-log*,

<sup>4</sup><https://github.com/ggml-org/llama.cpp>

Figure 5: Distribution comparison of each weight in Mamba-2 and Bi-Mamba modules (1st and 24th layers).

and  $D$ . The divergent weight distributions in Bi-Mamba suggest that Bi-Mamba intentionally captures broader values in the initial layers to retain sufficient information for binarized modules.

With more variability at the initial layers, Bi-Mamba can process the diverse initial features even in low-bit precision. In the mid-depth layers such as the 24th layer, the weight distribution of both the original Mamba and Bi-Mamba show similar patterns as in the first layer. However, the divergence is more moderate compared with the divergence in the first layer. This suggests that in the intermediate layers, Bi-Mamba can refine the intermediate representation with generalization with binarized weights. The distribution of all values and the final layer is present in the appendix Figure 9, 10, 11. In short, in the last layer, the divergence patterns also remain while the distribution is much narrower compared with previous layers, reflecting a more concentrated range of values.

Model	Zero-shot Acc. $\uparrow$								Perplexity $\downarrow$		
	BoolQ	PIQA	HS	WG	ARC-e	ARC-c	OBQA	Avg.	Wiki2	PTB	C4
Mamba-2-780M	61.5	71.8	54.9	60.2	54.3	28.5	36.2	52.5	11.8	20.0	16.5
Bi-Mamba (No KD)	50.5	65.8	37.8	50.9	39.7	23.8	30.4	42.7	14.9	30.9	15.6
Bi-Mamba (KL-Div)	56.8	66.5	38.1	51.6	39.8	22.7	28.2	43.3	15.0	27.3	15.6
Bi-Mamba (Phi-3.5)	49.6	66.8	39.0	53.2	40.6	23.7	30.8	43.4	14.5	27.3	16.6
Bi-Mamba	58.5	68.0	41.6	52.0	42.4	24.3	30.6	45.3	13.4	32.4	14.5

Table 9: Ablation study of **Bi-Mamba**. This table includes the performance comparison of different teachers and knowledge distillation strategies. Our autoregressive knowledge distillation brings improvement to the binarization-aware training regardless of the choice of teachers.

The focused distribution helps the model to generate a stable and reliable final representation. In all, our **Bi-Mamba** includes a much wider distribution to capture more information at the beginning stages while the distribution tends to be more centralized progressively to output stable final results.

## 5.7 Ablation Study

In this section, we provide the ablation study of **Bi-Mamba**. As shown in Table 9, we conduct various ablation studies in the 780M model including the model without knowledge distillation (w/o KD in the table), the model utilizing the KL divergence loss as distillation loss (KL Div in the table) and the model using a different teacher model (Phi-3.5-instruct-mini (Abdin et al., 2024)). The results demonstrate the importance of each component, as removing knowledge distillation (KD) or using alternate loss functions (KL Div and Phi-3.5) significantly reduces performance compared to the full Bi-Mamba model, which achieves the best results across all metrics except PTB. Specifically, Bi-mamba trained with original autoregressive loss obtains the lowest performance compared with other models trained with KD. The average accuracy on downstream tasks is 42.7, which is surpassed by the model trained with KL-Div loss, namely 43.3. With a different teacher, Phi-3.5, **Bi-Mamba** achieves similar performance as the model trained with Llama-2-7B as the teacher, demonstrating the effectiveness of our proposed autoregressive knowledge distillation.

## 6 Conclusion

We introduce **Bi-Mamba**, a scalable and efficient 1-bit Mamba architecture designed for large language models in multiple sizes: 780M, 1.3B, and 2.7B parameters. We begin by identifying the binarization space within the Mamba architecture. Then, **Bi-Mamba** models are trained from scratch on large datasets, similar to standard LLM pretraining, using an autoregressive distillation loss. Extensive language modeling experiments show that **Bi-Mamba** achieves competitive performance that is slightly lower than its full-precision counterparts (e.g., FP16 or BF16), while substantially reduces memory usage and computational cost compared to the original precision Mamba. This study provided a novel, first accessible and low-bit framework with linear computational complexity, laying the foundation for developing specialized hardware optimized for efficient 1-bit Mamba-based LLMs.

## Limitations and Ethical Statements

While **Bi-Mamba** achieves competitive performance to full-precision models, there may still be trade-offs in accuracy, particularly in complex tasks that rely heavily on nuanced language understanding. Also, full deployment may require specialized hardware to maximize efficiency gains, limiting accessibility on standard hardware setups. On ethical part, reducing model precision could risk oversimplifying nuanced patterns in data, potentially amplifying biases present in the training data. Moreover, while **Bi-Mamba** reduces energy consumption during inference, training binary models from scratch can still be computationally intensive.

## Appendix

### A More Experimental Results

#### A.1 Full Results on Downstream Tasks

We present the performance dynamics of the 2.7B and 1.3B Bi-Mamba models during training in terms of perplexity and multiple downstream tasks, as shown in Figure 6 and 7. Each configuration demonstrates different trade-offs between model performance and computational efficiency of Bi-Mamba across various datasets.

We can observe that both the 2.7B and 1.3B Bi-Mamba models consistently outperform GPTQ-2bit and BiLLM after reaching a certain training stage. Specifically, Bi-Mamba generally exhibits a gradual decrease in perplexity, indicating the effectiveness of the training. In some cases such as Bi-Mamba-2.7B on C4 dataset, the perplexity is even better than in the full-precision Mamba models. In downstream tasks such as ARC-C, ARC-E, HS, and PIQA, Bi-Mamba consistently outperforms Bi-LLM, indicating that it is a more effective low-bit quantization approach for maintaining accuracy across various data sizes.

Additionally, the performance on average increases steadily with more training costs. The overall trend demonstrates that Bi-Mamba provides a robust alternative, balancing computational efficiency with competitive performance. This makes Bi-Mamba particularly valuable in resource-constrained environments where some trade-off in precision is acceptable. At the current training stage, the models have not yet fully converged, indicating potential for further performance gains.

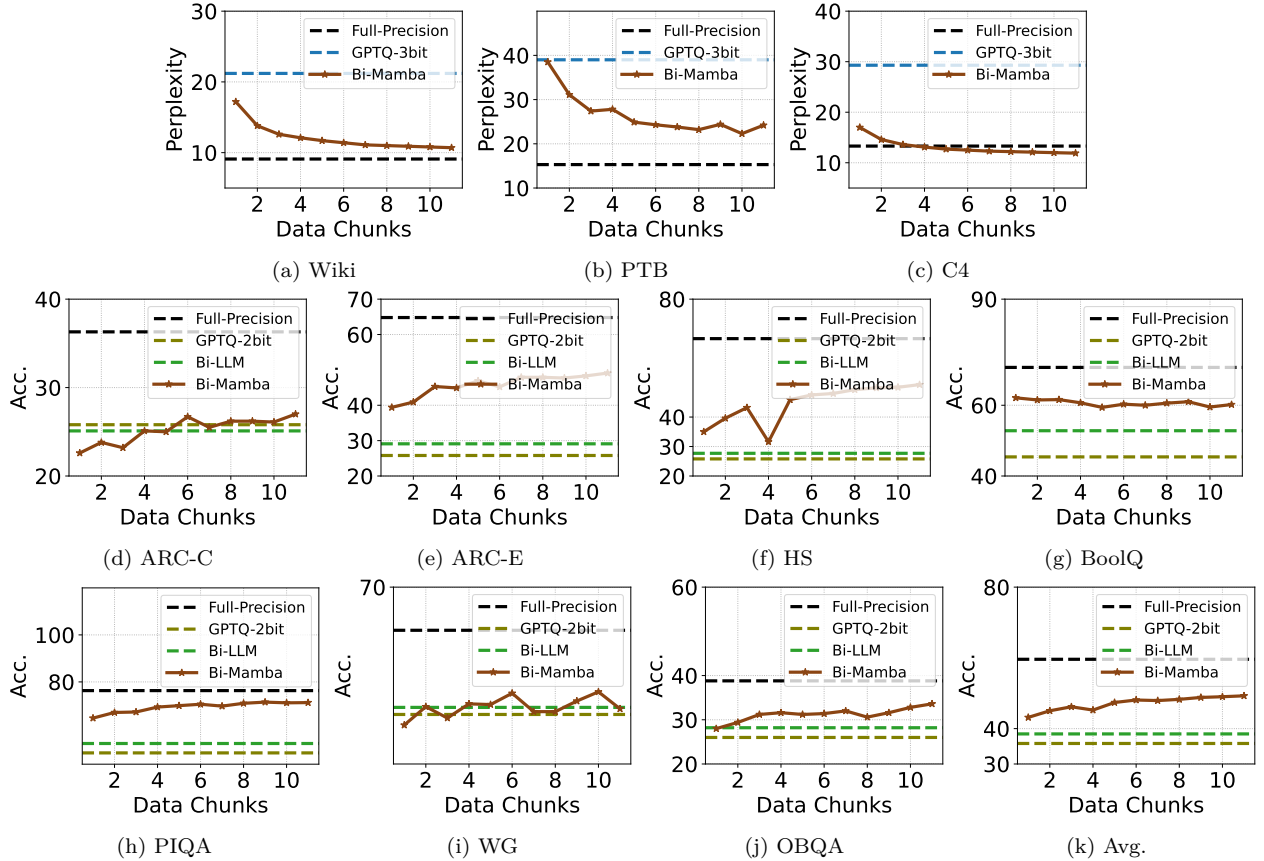

Figure 6: The downstream performance and perplexity curve of Bi-Mamba-2.7B with different training costs.

Figure 7: The downstream performance and perplexity curve of Bi-Mamba-1.3B with different training costs.

We provide the full results of the ablation study on downstream tasks, as shown in Table 9. Without knowledge distillation, the model obtains the lowest average zero-shot accuracy on downstream tasks. With knowledge distillation, Bi-Mamba achieves the highest accuracy on downstream tasks, demonstrating the effectiveness of our Bi-Mamba.

## A.2 Weight Distribution

We visualized the weight distributions of different modules in Mamba-2 (Orange histograms) and Bi-Mamba (Blue histograms), as shown in Figure 9, 10 and 11. We visualize the weight parameter distributions of different modules in the first (1st), mid (24th) and final (48th) layers of the corresponding 780M models. The input and output projection matrices are the values after re-scaling. Each pair of histograms compares how Bi-Mamba modifies the distribution of weights in different modules, no matter whether the module is binarized or not, illustrating the impact of Bi-Mamba on each module.

Specifically, in the first layer, the weight distribution of the original Mamba-2 such as *Conv1d.weight*, *Conv1d.bias* and *D* are tightly concentrated, indicating the strong focus on specific values. In contrast, the weight distribution in Bi-Mamba in the first layer is much divergent with additional peaks in the histograms such as in *A-log*, *Conv1d.bias* and *D*. The divergent weight distributions in Bi-Mamba suggest that Bi-Mamba intentionally captures broader values in the initial layers to retain sufficient information for binarized modules.

With more variability at the initial layers, Bi-Mamba can process the diverse initial features even in low-bit precision. In the mid-depth layers such as the 24th layer, the weight distribution of both the original Mamba and Bi-Mamba show similar patterns as in the first layer. However, the divergence is more moderate

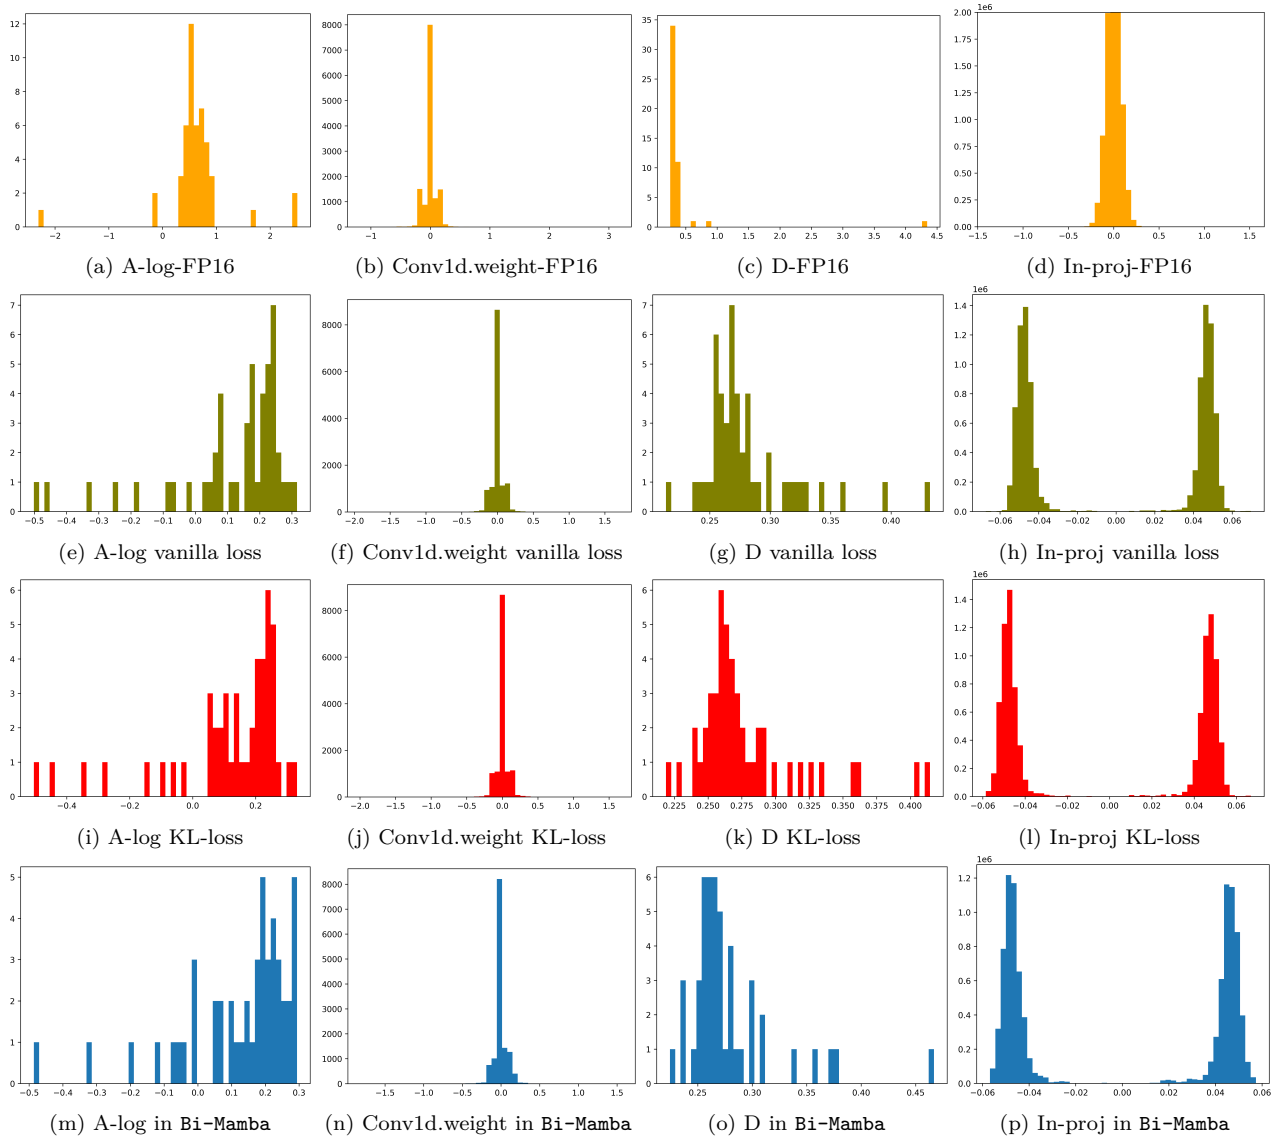

Figure 8: Distribution comparison of precision FP16 and different training objectives. It shows that different training objectives generate similar weight distributions.

compared with the divergence in the first layer. This suggests that in the intermediate layers, Bi-Mamba can refine the intermediate representation with generalization with binarized weights. Finally, in the last layer, the divergence patterns also remain while the distribution is much narrower compared with previous layers, reflecting a more concentrated range of values.

We also provide the weight distribution of different training objectives, as shown in Figure 8. With binarization, different training objectives including vanilla loss, KL-Divergence loss and our autoregressive loss, generate similar weight distribution after training.

The focused distribution helps to model to generate a stable and reliable final representation. In all, our Bi-Mamba includes a much wider distribution to capture more information at the beginning stages while the distribution tends to be more centralized progressively to output stable final results.

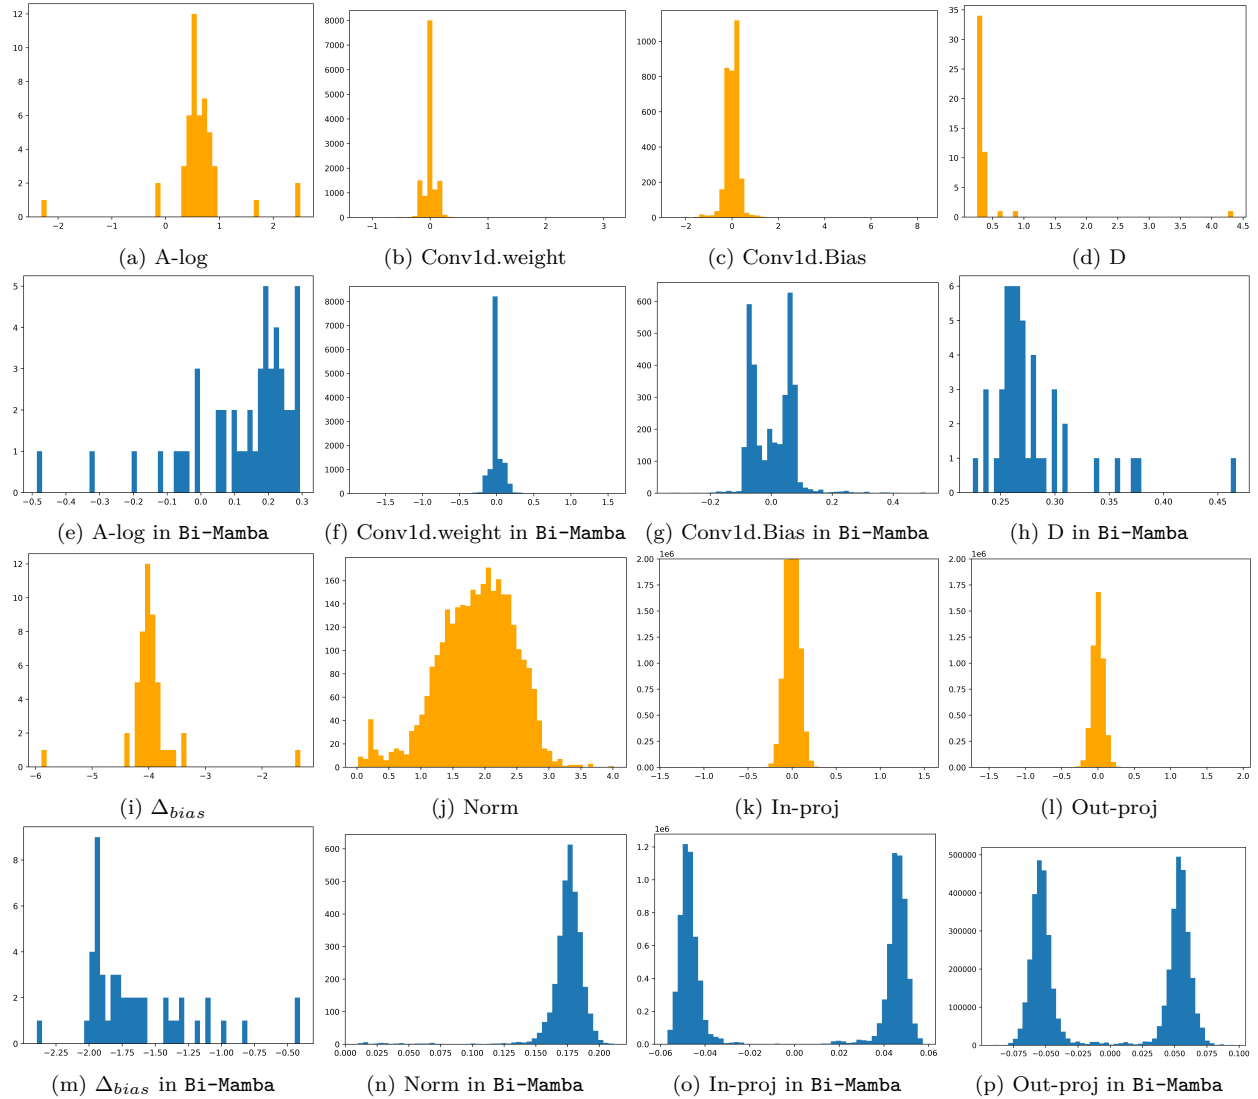

Figure 9: Distribution Comparison of each weight in Mamba-2 and Bi-Mamba modules at the 1st layer.

## B Generation Case

We provide generation cases from our models in different scales including 2.7B, 1.3B and 780M, and other baseline models including GPTQ-3bit, GPTQ-2bit and Bi-LLM as shown in Figure 12, 13 and 14.

It is observed that Mamba-2 consistently produces coherent answers with meaningful semantic information but often repeats the content excessively. **Bi-Mamba**, while also retaining coherence and context after binarization, also shows repetition, especially in phrases. Nevertheless, **Bi-Mamba** is more robust than other baseline methods in preserving relevant information.

Post-training quantization methods, particularly at lower bit levels (e.g., GPTQ-2bit and 1bit BiLLM), tend to produce meaningless or garbled content. Specifically, GPTQ-3bit occasionally provides coherent starts but quickly devolves into repetitive or nonsensical text, indicating limited content understanding and generation ability after quantization. Other low-bit settings such as GPTQ-2bit and Bi-LLM generally fail to maintain coherence for generation, resulting in meaningless symbols generation, especially in smaller models.

Figure 10: Distribution Comparison of each weight in Mamba-2 and Bi-Mamba modules at the 24th layer.

Figure 12: The generation cases for 2.7B models.
