Document Structure in Long-Document Transformers

Anonymous ACL submission

Abstract

 Long documents often exhibit structure with hierarchically organized elements of different functions, such as section headers and para- graphs. Despite the omnipresence of docu- ment structure, its role in natural language processing (NLP) remains opaque. Do long- document Transformer models acquire an in- ternal representation of document structure during pre-training? How can structural in- formation be communicated to a model after pre-training, and how does it influence down- stream performance? To answer these ques- tions, we develop a novel suite of probing tasks to assess structure-awareness of long-document 015 Transformers, propose general-purpose struc- ture infusion methods, and evaluate the ef- fects of structure infusion on QASPER and Evidence Inference, two challenging long- document NLP tasks. Results on LED and 020 LongT5 suggest that they acquire implicit un- derstanding of document structure during pre- training, which can be further enhanced by structure infusion, leading to improved end- task performance. To foster research on the 025 role of document structure in NLP modeling, 026 **we make our data and code publicly available^{[1](#page-0-0)}.**

027 1 Introduction

 Long documents such as news articles, scientific papers, and clinical reports play a vital role in many human activities. These documents are usually or- ganized into chapters, sections, subsections, and paragraphs, i.e. they are structured. This helps humans in navigating documents [\(Guthrie et al.,](#page-9-0) [1991;](#page-9-0) [Nguyen et al.,](#page-10-0) [2021\)](#page-10-0) and building a men- tal model of the content [\(Taylor and Beach,](#page-11-0) [1984;](#page-11-0) [Meyer et al.,](#page-10-1) [1980\)](#page-10-1). The example in Fig. [1](#page-0-1) shows how the hierarchy of sections and subsections helps when looking for the size of a dataset in an NLP paper: one would go via the "Experiments" section to the "Datasets" subsection.

Figure 1: Transformer models receive unstructured text as input (top right) – yet long texts exhibit structure, which helps in finding information (bottom). We investigate whether Transformers learn representations of document structure during pre-training ([§4\)](#page-2-0), whether structure-awareness can be enhanced by infusion after pre-training ([§5\)](#page-3-0), and what effects infusion has on downstream task performance. Source: QASPER dataset, arxiv ID 1909.00694 [\(Dasigi et al.,](#page-9-1) [2021\)](#page-9-1).

Although structure is omnipresent and useful to **041** humans, existing long-document Transformers (e.g. **042** [Ainslie et al.](#page-9-2) [2020;](#page-9-2) [Beltagy et al.](#page-9-3) [2020;](#page-9-3) [Ivgi et al.](#page-10-2) **043** [2023\)](#page-10-2) operate with linearized textual input: doc- **044** uments are converted to flat character strings, re- **045** moving the distinction between different functional **046** elements and their hierarchy (Fig. [1,](#page-0-1) top right). **047**

Understanding the structural capabilities of long- **048** document Transformers is important both theoreti- **049** cally and practically. From a theoretical standpoint, **050** prior work in probing has demonstrated the ability **051** of Transformers to learn syntactic representations **052** on the sentence level [\(Hewitt and Liang,](#page-10-3) [2019\)](#page-10-3) **053** – yet little is known about the ability to induce **054** higher-level discourse structures from linearized **055** text. Probing methodology and datasets for this **056** investigation are missing. From a practical per- **057** spective, recent works demonstrate that structure- **058**

 aware modeling can improve downstream task per- formance [\(Li et al.,](#page-10-4) [2023;](#page-10-4) [Cao and Wang,](#page-9-4) [2022;](#page-9-4) [Ruan et al.,](#page-11-1) [2022\)](#page-11-1) – yet existing studies are limited to task-specific architectures and data formats, mak- ing it hard to generalize the findings to new tasks and document types. General-purpose methodol- ogy for communicating structural information to Transformer models is yet to be established.

 Our work aims to close this gap. Instead of com- mitting to a specific document format, we build upon a task- and format-agnostic formalism of In- tertextual graphs (ITG, [Kuznetsov et al.](#page-10-5) [2022\)](#page-10-5) to encode structure obtained from the original doc- uments. Using this formalism, we (1) devise a novel suite of probing tasks to investigate structure- awareness of pre-trained Transformer models. We then (2) introduce a general-purpose structure infu- sion kit that allows communicating information about document structure to Transformers, and (3) investigate the impact of document structure on end-task performance using two widely used [l](#page-9-3)ong-document Transformer models – LED [\(Belt-](#page-9-3) [agy et al.,](#page-9-3) [2020\)](#page-9-3) and LongT5 [\(Guo et al.,](#page-9-5) [2022\)](#page-9-5) – and two challenging long-document NLP datasets – QASPER [\(Dasigi et al.,](#page-9-1) [2021\)](#page-9-1) and Evidence Infer- ence [\(DeYoung et al.,](#page-9-6) [2020\)](#page-9-6). Our findings suggest that Transformers do acquire an implicit notion of document structure during pre-training, and that their structure-awareness can be enhanced via in- fusion, leading to up to 6.8 F1 points increase on downstream tasks. Our work lays the foundation for the systematic analysis of the role of document structure in long document modeling.

⁰⁹² 2 Background

Figure 2: Document Graph. Black arrows show parent edges, next edges between alphabetically consecutive nodes are omitted for clarity. Node depth and node type information are infused in [§5.](#page-3-0)

093 Document structure. The term "structure" is **094** used ambiguously for textual documents. *Rhetor-* *ical structure* is the hierarchical organization of **095** semantic units, usually latent and not available for 096 explicit processing. [\(Kintsch and van Dijk,](#page-10-6) [1978;](#page-10-6) **097** [Mann and Thompson,](#page-10-7) [1987\)](#page-10-7). *Abstract structure* **098** refers to the hierarchical organization of a text into **099** elements such as sections, paragraphs, and $lists²$ $lists²$ $lists²$ [\(Nunberg,](#page-10-8) [1990;](#page-10-8) [Power et al.,](#page-10-9) [2003\)](#page-10-9). *Concrete*, **101** or *visual structure*, includes aspects of typesetting **102** such as font size, spacing and the location of textual **103** elements in a typeset text, classically ordered into **104** pages [\(Power et al.,](#page-10-9) [2003\)](#page-10-9). In this work, we focus **105** on the study of abstract document structure as the **106** direct author expression of textual organization. **107**

100

. **126**

Long-document Transformers. The memory **108** and computational requirements of the standard **109** Transformer architecture [\(Vaswani et al.,](#page-11-2) [2017\)](#page-11-2) **110** scale quadratically with the input length, making **111** it hard to process long documents under compu- **112** tational constraints. Several innovations for in- **113** creased efficiency have been proposed, surveyed by **114** Tay et al. [\(2022\)](#page-11-3). A popular and well-performing **115** approach is the combination of local attention with **116** [a](#page-9-2) varied distribution of global attention [\(Ainslie](#page-9-2) **117** [et al.,](#page-9-2) [2020;](#page-9-2) [Beltagy et al.,](#page-9-3) [2020;](#page-9-3) [Guo et al.,](#page-9-5) [2022\)](#page-9-5), **118** used by the top 5 models in the Scrolls bench- **119** mark for long-document processing [\(Shaham et al.,](#page-11-4) **120** [2022\)](#page-11-4). We experiment with two representatives for **121** this approach: LED [\(Beltagy et al.,](#page-9-3) [2020\)](#page-9-3), which is **122** employed in many recent works on long documents **123** (e.g. [Dasigi et al.](#page-9-1) [2021;](#page-9-1) [Cao and Wang](#page-9-4) [2022\)](#page-9-4) and **124** LongT5 [\(Guo et al.,](#page-9-5) [2022\)](#page-9-5), the best "base" model **125** on the Scrolls leaderboard at the time of writing^{[3](#page-1-1)}.

Probing. Probing tasks are diagnostic classifica- **127** tion tasks which investigate whether a linguistic **128** feature (e.g. sentence length, word content or syn- **129** [t](#page-9-7)ax tree depth) is encoded in a representation [\(Con-](#page-9-7) **130** [neau et al.,](#page-9-7) [2018;](#page-9-7) [Belinkov,](#page-9-8) [2022;](#page-9-8) [Rogers et al.,](#page-11-5) **131** [2020\)](#page-11-5). Early work on probing measured the en- **132** coded knowledge through the delta to a majority **133** baseline or randomly initialized embeddings. Con- **134** trol tasks were introduced as a better approximation **135** of what a probing classifier is able to learn in its **136** own neural representation compared to what lin- **137** guistic features it can extract from the underlying **138** representations [\(Hewitt and Liang,](#page-10-3) [2019\)](#page-10-3). We fol- **139** low this line of work by designing a novel atomic **140**

 2 Power et al. [\(2003\)](#page-10-9) include phenomena such as emphasis and quotation into abstract document structure. They are not considered here, as they are rarely preserved or standardized. 3 [https://www.scrolls-benchmark.com/](https://www.scrolls-benchmark.com/leaderboard)

[leaderboard](https://www.scrolls-benchmark.com/leaderboard), October 2023.

 control setting where we remove contextual infor- mation. To measure contextual information beyond a given span, we employ edge probing introduced by Tenney et al., [\(2019\)](#page-11-6).

 Syntax trees have been shown to be encoded in **BERT** [\(Hewitt and Manning,](#page-10-10) [2019\)](#page-10-10), but the repre- sentation of higher-order document structure has not been investigated. For the first time, we show that long-document Transformers internally repre- sent several aspects of document structure, and that this internal representation can be enhanced.

 Document structure in Transformers. Existing approaches that make use of document structure in Transformers broadly fall into two categories. In *hi- erarchical processing* [\(Zhang et al.,](#page-11-7) [2022;](#page-11-7) [Qi et al.,](#page-10-11) [2022;](#page-10-11) [Liu and Lapata,](#page-10-12) [2019;](#page-10-12) [Ruan et al.,](#page-11-1) [2022\)](#page-11-1), complex, task specific architectures are built, from which results and analyses are hard to generalize. In *structure infusion*, additional structural informa- tion is added to pre-trained Transformer models. We employ the latter setting, because methods and models can be reused and analyzed more easily. [S](#page-9-9)tructure infusion through special tokens [\(Agha-](#page-9-9) [janyan et al.](#page-9-9) [2022;](#page-9-9) [Fisch et al.](#page-9-10) [2019\)](#page-9-10), attention masks [\(Liu et al.,](#page-10-13) [2021;](#page-10-13) [Hong et al.,](#page-10-14) [2022\)](#page-10-14), absolute [\(Bai et al.](#page-9-11) [2021\)](#page-9-11) or relative position embeddings [\(Cao and Wang,](#page-9-4) [2022\)](#page-9-4) has been shown to improve downstream task performance. Here, we combine special tokens and position embeddings which only require changes at the input layer, making them easily transferrable to other transformer models.

¹⁷² 3 Representing Structure

 Formalism. We model the abstract structure of a document [\(Power et al.](#page-10-9) [2003,](#page-10-9) see [§2\)](#page-1-2) as an ordered graph G (Fig. [2\)](#page-1-3) as in Kuznetsov et al. [\(2022\)](#page-10-5), using their notation. Structural el- ements such as section headings or paragraphs **are represented as a set of typed nodes** N^G . The node types correspond to the *function* of the element in the document. We consider the types article-title, section-title, 182 abstract, and paragraph^{[4](#page-2-1)}. The set of typed, 183 directed edges E^G encodes the *hierarchical organi- zation* of the textual elements with parent edges and the linear order with next edges. Node func- tion and hierarchical organization can be seen as orthogonal pieces of information that together fully describe the abstract document structure.

> ⁴We do not consider sentences, as their borders often cannot be extracted unambiguously from English texts.

Data conversion. All datasets used in the present **189** work were converted to the intertextual graph (ITG) **190** format^{[5](#page-2-2)} introduced in Kuznetsov et al. [\(2022\)](#page-10-5), 191 which is a JSON representation of the graph data 192 structure introduced above. All our methods and **193** experiments are based on this format, and therefore **194** dataset agnostic, easily adaptable, and extensible. **195**

4 Probing for Structure 196

4.1 Probing Suite Design 197

As the first step towards the systematic study of **198** document structure in long document processing, **199** we propose a suite of seven probing tasks that **200** measure the ability of pre-trained Transformers **201** to capture structural information from their input, **202** described in Tab. [1.](#page-3-1) For example, the parent **²⁰³** predecessor probe measures the representa- **²⁰⁴** tion of document hierarchy in a Transformer by **205** learning to distinguish between pairs of document **206** elements (e.g. headings or paragraphs) that are in **207** a parent-child relationship and pairs that are not. **208** As shown in our introduction example, a good rep- **209** resentation of the hierarchy can help in locating **210** relevant information in a document (Fig. [1\)](#page-0-1). **211**

All probing tasks are cast as classification and **212** evaluated via accuracy. Assuming a model that **213** computes vector representations of textual nodes, **214** classification is implemented as a linear layer pro- **215** jecting from the representation of a node or a node **216** pair to the label space. If a model has multiple **217** layers, node representations are computed as a **218** weighted sum [\(Tenney et al.,](#page-11-6) [2019\)](#page-11-6) of the representations from each layer. For tasks on node pairs, **220** the representations of two nodes are concatenated. **221** Only the linear layer and the scalar mix weights **222** are updated during training on the probing task. **223**

4.2 Experiments and Results **224**

Probing dataset. We instantiate our probing **225** tasks with research papers from the open sci- **226** ence platform F1000Research^{[6](#page-2-3)}. Based on the 227 pre-processing used for the F1000RD corpus **228** [\(Kuznetsov et al.,](#page-10-5) [2022\)](#page-10-5) we convert each paper into **229** the ITG format (Fig. [2\)](#page-1-3), removing all non-textual **230** nodes[7](#page-2-4) . Removing all papers exceeding the maxi- **231** mum input length of LED (16384 tokens) results **232**

⁵[https://github.com/UKPLab/](https://github.com/UKPLab/intertext-graph) [intertext-graph](https://github.com/UKPLab/intertext-graph)

⁶<https://F1000research.com>, downloaded on April 9th, 2021. We use the paper first versions.

⁷For the node type probe we remove the document title and abstract as well, as these occur once per document.

Name	Classification task	Labels
Node type	Type of n_i with all nodes of type section and a	Section,
	tree depth > 1 grouped as subsection[1].	subsection,
		paragraph
Sibling	Do n_i and n_k share the same parent n_p ?	Boolean
Ancestor	Is n_i on the parent path of n_k and the root n_0 ?	Boolean
Position	Position within an ordered set S for all nodes $n_i \in$	Begin, inside,
	S with the same parent n_p .	outside
Parent predecessor	Is n_p the parent of n_i ?	Boolean
Tree depth	Depth of n_i from the root n_0 .	Integer
Structural	Shortest parent path between n_i and n_k .	Integer

Table 1: Definitions of probing tasks and their labels. $n_{j,k,p,0}$ denote nodes in the document graph G. [1] Subsection is a mixture of functional and hierarchical description, so it is not part of the node types defined in [§3.](#page-2-5) It is added to the node type probing task to increase the difficulty.

 in a corpus of 2,499 documents. All probing tasks are balanced through downsampling on document basis, meaning that the label distribution is uniform in most cases (Tab. [5\)](#page-13-0). For some probes, e.g. tree depth, not all labels occur in all documents, re-sulting in a non-uniform label distribution.

 Probing architecture. We compare probing of the "vanilla" LED and LongT5 encoders with two control configurations each: *atomic* and *random*. In the atomic control (Fig. [3\)](#page-4-0), nodes are input to the model individually, i.e. without their document context. Comparing the vanilla and atomic configu- rations shows the effect of contextualization on the representation of structure. For the random control, all model weights except for the embedding layer are re-initialized randomly [\(Jawahar et al.,](#page-10-15) [2019\)](#page-10-15). It shows the effect of pre-training on the represen- tation of structure. Details on implementation and hyperparameters can be found in Appx. [B.2.](#page-11-8)

 Results. In all probes, the accuracy of the vanilla model is higher than the random control (Tab. [2\)](#page-5-0). The difference varies between 34% for LongT5 on position and 2.7% for LED on node type – a magnitude comparable to reported results from prior work on probing (e.g. [Conia and Navigli](#page-9-12) [2022\)](#page-9-12). This result suggests that LED and LongT5 learn to represent document structure during pre- training, but the effect varies between different as- pects of document structure. The cases with small difference between vanilla and random control im- ply that the input token and position embeddings, not being re-initialized, contain much of the infor- mation needed to solve the task. The scores of the atomic control are lower than those of the vanilla

configuration on all probes, showing that context **267** helps to represent document structure. **268**

Vanilla LED and LongT5 achieve accuracies of **269** 0.9 on some probes, e.g. node type, suggest- **²⁷⁰** ing that they are able to encode some aspects of **271** structural information well even without its explicit **272** input. It is surprising that the accuracy on the **273** sibling probe is far below that of parent **²⁷⁴** predecessor, because the information on the **²⁷⁵** parents of two nodes is enough to determine their **276** siblinghood. It seems that the combination of par- **277** ent information from two nodes in a queried pair is **278** difficult. The structural probe can be consid- **²⁷⁹** ered the most complex, as it has the most classes. **280** Thus, the large room for improvement is expected. **281**

We could show for the first time that long- **282** document Transformers can learn to represent doc- **283** ument structure, even though the models were not **284** explicitly trained for this. However, the representa- **285** tion of some aspects of structure is far from optimal. **286** In the following, we investigate whether structure **287** infusion, i.e. the input of additional, explicit infor- **288** mation on document structure, improves the inter- **289** nal representation of structure and if this translates **290** to improvements on downstream tasks. **291**

5 Infusing Structure **²⁹²**

As exemplified in Fig. [1,](#page-0-1) structure can help hu- **293** mans in working with documents. While previous **294** work shows that the addition of structural informa- **295** tion can improve the downstream performance of **296** Transformer models [\(Li et al.,](#page-10-4) [2023;](#page-10-4) [Cao and Wang,](#page-9-4) **297** [2022;](#page-9-4) [Ruan et al.,](#page-11-1) [2022\)](#page-11-1), the use of task-specific **298** architectures and document formats prevents com- **299**

Figure 3: Probing classifier with the vanilla probing architecture encoding a full document (left) and the atomic encoding two nodes individually without any context (right). Tokens w/ arrow are used as input to the next layer.

Figure 4: Structure infusion via special tokens and embeddings. Special tokens ("<Ti>", "<Ab>") are prepended to the text of the corresponding node, embeddings are summed with the token embeddings. The figure shows the combination of hierarchical embeddings and node type special tokens, short description tok-type-emb-depth.

 parison of structure infusion methods across the studies, and makes it challenging to relate perfor- mance to probing results. To remedy this, we intro- duce a task- and format-agnostic structure infusion kit, and demonstrate its wide applicability by study- ing the effects of structure infusion on LED and LongT5 and two challenging long-document tasks.

5.1 Methodology [8](#page-4-1)

 Structure infusion. We infuse structural infor- mation through position embeddings added to the token embeddings (indicated as emb, see Fig. [4\)](#page-4-2) and special tokens that are prepended to the tokens of the corresponding node (tok). Both methods only modify the input layer and are therefore easily applicable to any Transformer model.

 We infuse the two types of abstract structural information that are missing in the input of Trans- former models ([§3\)](#page-2-5): node function and hierar- chy. Node function is infused through embed- dings and special tokens representing the node type (type). To infuse the hierarchical organization, to- kens and embeddings represent the depth of a node in the graph, i.e. its distance to the document root (depth). As a baseline for structural tokens, we prepend each node with the same separator token (sep). We refer to the infusion configurations us- ing short descriptors, e.g. the combination of node depth position embeddings and node type tokens is

shortened to emb-depth-tok-type. **³²⁸**

Probing. The probing experiments were con- **329** ducted as described in [§4](#page-2-0) using the same probing **330** dataset, with the addition of structural information **331** in the input. We omit the atomic and random con- **332** trol here, as we are interested in the capabilities of **333** the configuration that is used for downstream tasks. **334**

Downstream task datasets. We selected **335** QASPER [\(Dasigi et al.,](#page-9-1) [2021\)](#page-9-1) and Evidence **336** Inference [\(DeYoung et al.,](#page-9-6) [2020\)](#page-9-6) by the following **337** criteria: they are based on long documents, abstract **338** document structure is available, and several types **339** of downstream tasks are covered, to see possible **340** differences in the effect of structure infusion. **341**

QASPER is a collection of scientific papers **342** from computational linguistics / NLP and corre- **343** sponding questions with one or multiple answers **344** with evidence. We model question answering as a 345 generative problem and evidence selection as para- **346** graph classification. Answer generation and evi- **347** dence selection are evaluated with F1 scores using **348** the evaluation script provided by the authors^{[9](#page-4-3)}.

Evidence Inference consists of reports from **350** clinical studies, "prompts" in the form of *inter-* **351** *vention*, *comparator*, and *outcome*, one or multi- **352** ple labels for the prompt ("significantly increased", **353** "significantly decreased", or "no significant dif- **354** ference") and corresponding evidence spans. We **355**

. **349**

⁸We provide implementation details in Appx. [B.3-](#page-14-0)[B.6.](#page-16-0)

 model prompt answering as 3-way classification, and convert evidence span selection to node classi- fication by mapping evidence spans to nodes. As there is no adaptable evaluation script, and for con- sistency with QASPER, we re-implemented eval- uation, choosing the annotation resulting in the highest score as gold standard. This means that we can only compare the models in our work.

 Training Downstream tasks were fine-tuned for 10,200 steps with an effective batch size of 8 in a multi task fashion. We report mean test set results of 3 random seeds.

 In all experiments in this section, the models were pre-trained for 15,000 steps, with an effec- tive batch size of 16, with the respective struc- ture infusion configuration on the relevant probing (F1000RD) or downstream task dataset (QASPER or Evidence Inference), as we noted this to be beneficial in early experiments [\(Gururangan et al.,](#page-9-13) [2020\)](#page-9-13). "T5-style" denoising [\(Raffel et al.,](#page-10-16) [2020\)](#page-10-16) was used as the pre-training task as suggested in Xiong et al, [\(2022\)](#page-11-9).

378 5.2 Probing of Structure-Infused Models

 We see an improvement in all probes through struc- ture infusion (Fig. [5,](#page-5-1) Tab. [4\)](#page-12-0). The node type and tree depth probes show an accuracy of around 1 with tree depth infusion, as this informa- tion suffices to solve the tasks. Node type infusion does not lead to perfect scores on the node type probe, as the subsection node type is part of the probing task, but not of the infusion (Tab. [1\)](#page-3-1).

 Except for LongT5 on sibling, infusion of node depth results in higher accuracy than node type or node boundary information infused on the same pathway. For the majority of LED probes (sibling, position, tree depth, and structural), models with position embed- ding infusion show higher metrics than their coun- terparts with the same information in special tokens, while for LongT5, the results are mixed. LED, based on BART [\(Lewis et al.,](#page-10-17) [2020\)](#page-10-17), is pre-trained with absolute position embeddings like our struc- [t](#page-10-16)ural embeddings, while LongT5, based on T5 [\(Raf-](#page-10-16) [fel et al.,](#page-10-16) [2020\)](#page-10-16), uses relative position embeddings. LED might therefore have a better capability to use the information from absolute embeddings.

402 5.3 Structure infusion in Downstream Tasks

403 QASPER For LED in answer generation, the **⁴⁰⁴** emb-type-tok-depth configuration results in the best performance, with an improvement of 2.28 405 F1 points over vanilla (Tab. [3\)](#page-5-2). In evidence selec- **406** tion, emb-depth-tok-depth outperforms the **⁴⁰⁷** vanilla configuration by 2.59 F1 points. This is an **408** improvement of 5.58 F1 points for answer gener- **409** ation and 14.04 F1 points for evidence selection **410** [o](#page-9-14)ver the LED state-of-the-art (SOTA) [\(Caciularu](#page-9-14) **411** [et al.,](#page-9-14) [2022\)](#page-9-14) on QASPER. The vanilla configuration **412** already outperforms the SOTA by 3.30 and 11.45 **413** F1 points, respectively. Infusing the node depth **414** through two pathways improves over a single path- **415** way. While unintuitive, this was also observed for **416** the sibling, parent predecessor, and **⁴¹⁷** tree depth probes (Fig. [5\)](#page-5-1). **⁴¹⁸**

For LongT5, special tokens structure infusion **419** results in the highest scores. The best answer F1 of **420** 46.76 with node type tokens improves the vanilla **421** model by 0.87 points and is slightly higher than **422** the current LongT5-base SOTA of 46.6 [\(Guo et al.,](#page-9-5) **423** [2022\)](#page-9-5). In evidence selection, infusion of depth **424** tokens increases the vanilla configuration by 4.05 **425** F1 points. To our knowledge, there are no reported **426** scores for LongT5 on QASPER evidence selection. **427**

Evidence Inference For LED, the best per- **428** formance in classification is obtained by the **429** emb-depth-tok-type configuration, improv- **⁴³⁰** ing 2.19 F1 points over the vanilla configuration. **431** In evidence selection, emb-depth-tok-depth **⁴³²** outperforms the vanilla baseline by 5.52 F1 points, **433** but adding node separator tokens already leads to **434** an increase of 5.26 F1 points. **435**

For LongT5, no structure infused variant outper- **436** forms vanilla in classification, while in evidence **437** selection, emb-type-tok-type outperforms **⁴³⁸** vanilla by 6.84 F1 points. **439**

Comparison of infusion configurations. In **440** most cases, adding node separator tokens improves **441** performance. This was expected, as it is common **442** practice to signify segment boundaries to models **443** (e.g. [Beltagy et al.](#page-9-3) [2020\)](#page-9-3) and could also be seen **444** in probing. For LED, the combination of position **445** embeddings and structural tokens exhibits the best **446** scores, which again resembles the probing results. **447** For LongT5, combining both infusion pathways **448** only results in the best scores on Evidence Infer- **449** ence evidence selection. Infusion via structural **450** tokens outperforms infusion via position embed- **451** dings for LongT5 on most subtasks. **452**

The increases for LED of about 2 F1 points **453** are similar to the reported performance increases **454**

 through document structure infusion on other long- document datasets, showing that our employed methods are effective. These works use relative position embeddings [\(Cao and Wang,](#page-9-4) [2022\)](#page-9-4) or spe- cial attention patterns [\(Liu et al.,](#page-10-13) [2021;](#page-10-13) [Hong et al.,](#page-10-14) [2022\)](#page-10-14), while we use structural tokens and absolute position embeddings. Our methods are easier to ap- ply and adapt, as only the input to the model needs to be modified. For LongT5, the performance gains through structure infusion of up to 6.84 F1 points suggest that this is a promising research direction.

466 5.4 Correlation between Probing and **467** Downstream Tasks

Figure 6: Pearson correlation between probing and downstream tasks. $*$ denotes significance ($p < 0.05$).

 To find associations between the representation of document structure and downstream task per- formance, we computed the Pearson correlation between probing and downstream task metrics [10](#page-7-0) **⁴⁷¹** (Fig. [6\)](#page-7-1). All combinations of probing and down- stream tasks for LED, and evidence selection and all probing tasks for LongT5 have a correlation greater or around 0. In contrast, the performance of LongT5 on QASPER answer generation and Ev- idence Inference classification is mostly negatively correlated with the probing task metrics. These were also the tasks with the least improvements through structure infusion. As they are decoder- based tasks, while evidence selection is encoder- based ([§B.5\)](#page-15-0), it seems that LongT5 has less need for structure infusion on decoder-based tasks.

 For LED in both QASPER subtasks and Evi- dence Inference classification and for LongT5 in evidence selection on both Evidence Inference **and QASPER, we see significant** $(p < 0.05)$

correlation with the ancestor and parent **⁴⁸⁸** predecessor probes, which measure the rep- **⁴⁸⁹** resentation of relations between nodes on one di- **490** rected path of parent edges. These usually have **⁴⁹¹** more defined semantic relationships among each **492** other compared to nodes from different paths, e.g. **493** a section heading has more relevant information **494** about the paragraphs belonging to that section than **495** about those in other sections. Our results suggest **496** that better representation of these relations is asso- **497** ciated with better downstream performance. **498**

6 Conclusion **⁴⁹⁹**

In this work, we provided an in-depth analysis of **500** the representation of abstract document structure **501** in long-document Transformers. Experiments with **502** our novel probing suite show that LED and LongT5 **503** have learned to represent node function and hier- 504 archical organization through pre-training without **505** explicit supervision, with room for improvement. **506**

To investigate the effect of infusing the aspects **507** of document structure that are missing in Trans- **508** former inputs due to linearization, we developed **509** a modular structure infusion framework. Probing **510** shows that structure infusion enhances the internal 511 representation of document structure, and we see **512** performance improvements from structure infusion **513** on QASPER and Evidence Inference, two down- **514** stream tasks where this has not been shown before. **515** The significant correlation between several probing **516** and downstream tasks suggests that it is indeed the **517** improved representation of document structure that **518** leads to downstream task performance gains. **519**

Our probing, structure infusion and downstream **520** task suite is easily extensible with new probing **521** and downstream tasks and new types of infused **522** information. While this work provides proof of **523** the utility of our graph-based framework for doc- **524** uments from the scientific domain, the framework **525** can be applied to other document types (e.g. web **526** pages or conversation threads). Given that the ad- **527** dition of separator tokens between document ele- **528** ments can already increase performance, we deem **529** applying our methods to documents with less well- **530** defined structure promising. Our probing methods **531** are fully compatible with the current generation of **532** Transformer-based LLMs [\(BigScience Workshop,](#page-9-15) **533** [2023;](#page-9-15) [Touvron et al.,](#page-11-10) [2023\)](#page-11-10), as long as the internal **534** states of the model can be accessed. We hope that **535** our contributions pave the path towards systematic **536** study of the role of document structure in NLP. **537**

¹⁰The absolute values from each set of bars in Fig. [5](#page-5-1) were paired with the unaggregated values from each column in Tab. [3](#page-5-2) for the same model.

⁵³⁸ Ethical Considerations

 Long documents lie at the core of text work, and structure is omnipresent in long documents. We believe that developing a better understanding of the role of document structure in NLP would allow us to build more efficient, robust, and interpretable systems for the analysis of long texts. We envision a trade-off between structural modeling capabili- ties of NLP systems (which, as we show, can be enhanced by providing explicit document structure) and the computational and storage overhead associ- ated with processing additional structural informa- tion in the documents. Future work would inves- tigate this trade-off and determine in which cases this overhead is justified. As document structure is openly present in documents and easily accessible by humans, we do not envision additional ethical risks or misuse scenarios due to the use of docu- ment structure in NLP modeling. Our work only uses data published under permissive licenses; our adaptations of this data are made available under permissive conditions as well.

⁵⁶⁰ Limitations

 We see our work as an important step towards the general study of the role of document structure in NLP modeling. Below we outline the limitations of our work, which present excellent opportunities for follow-up research.

 Dataset diversity. Our work unifies structured document data from multiple sources. Yet all of this data originates form the scientific domain. There are several benefits to this: scientific documents are long, clearly licensed, and exhibit structure – and the scientific domain offers multiple long- document processing tasks. In addition, focusing on one general domain allows us to control for domain shift during our measurements. We note that no part of our methodology is tailored to the particularities of the scientific domain – and as long as source documents can be converted into the domain-agnostic ITG formalism, our methods should be easily adaptable to other domains like Wikipedia or conversation threads. Similarly, we limit our studies to the English language, as other languages face scarcity both in terms of available long-document Transformer models and academic texts. As more data and models become available, it will become possible to evaluate our findings in new contexts.

probing tasks coupled with a range of structure infu- **588** sion methods, resulting in a wide experimental grid. **589** To make in-depth analysis feasible, we had to limit **590** our focus on a few models and tasks. We chose **591** two datasets which combine generative question **592** answering, segment classification and document **593** classification. Our experiments show that structure **594** infusion can be useful for all tasks and models con- **595** sidered. This suggests that experiments on other **596** tasks are a promising direction for future research, **597** which is facilitated by our open implementation. 598

Large language models. While it would be **599** technically possible to apply our kit to the recent **600** [d](#page-11-10)ecoder-only models such as LLaMA [\(Touvron](#page-11-10) **601** [et al.,](#page-11-10) [2023\)](#page-11-10) or BLOOM [\(Fan et al.,](#page-9-16) [2022\)](#page-9-16), this **602** would require substantial computational resources **603** – which illustrates the challenges of long-document **604** processing by modern NLP models and does not **605** constitute a limitation of our proposed approach. **606** Similarly, commercially hosted models with in- **607** creased input length such as GPT-4[11](#page-8-0) (32k tokens) **⁶⁰⁸** and Claude [12](#page-8-1) (100k tokens) could be evaluated **⁶⁰⁹** and infused with document structure – yet their **610** closed-source nature and lack of access to model **611** weights prevents such investigation. We hope that **612** the progress in efficient NLP and the ongoing open- **613** source LLM development make such studies possi- **614** ble in the near future. 615

Correlated model states. The structure-infused **616** models in this work were first pre-trained using a **617** language modeling loss on probing or downstream **618** task data, and then further fine-tuned using a task- **619** specific loss. The probing and downstream task **620** datasets in our work are *not identical*; thus, strictly **621** speaking, the scores used to compute the correla- **622** tion in Fig. [6](#page-7-1) come from models with the same **623** structure infusion configuration, but not the same **624** *state*. We believe this to be unproblematic and ex- **625** pect the states to be comparable, since each model **626** is pre-trained under the same regime. To confirm **627** this, future work could create probing datasets from **628** downstream task datasets to use the same model **629** state in probing and downstream tasks – at the cost **630** of a drastic increase in the number of probing ex- **631** periments. This technical limitation only pertains **632** to [§5.4](#page-7-2) and Fig. [6](#page-7-1) and leaves all other results unaf- **633** fected. 634

587 Models and Tasks. Our setup involves multiple

A Table of Probing Results **⁹³⁸**

See Tab. [4](#page-12-0) 939

B Implementation Details **940**

B.1 Models 941

In all experiments, we used the huggingface Trans- **942** formers[13](#page-11-11) [\(Wolf et al.,](#page-11-12) [2020\)](#page-11-12) implementations and **⁹⁴³** [w](#page-9-3)eights of LED base (162M parameters, [Beltagy](#page-9-3) **944** [et al.](#page-9-3) [2020\)](#page-9-3) and LongT5 base with transient global **945** attention (220M parameters, [Guo et al.](#page-9-5) [2022\)](#page-9-5). **946**

B.2 Probing 947

Dataset. Our probing dataset is split $0.6/0.2/0.2$ 948 across train, dev, and test using in-document bal- **949** ancing. For boolean and the position probe we **⁹⁵⁰** see a uniform distribution of instances per label, **951** compared to the node type probe where sub- **⁹⁵²** sections occur not in all documents, resulting in a **953** non-uniform distribution. The structural and **⁹⁵⁴** tree depth probes naturally feature a diverse **⁹⁵⁵** set of labels and instances. A full overview of the **956** label distribution can be found in Tab. [5.](#page-13-0)

Implementation and hyperparamenters. Our **958** probing kit is implemented using the AllenNLP **959** library [\(Gardner et al.,](#page-9-17) [2018\)](#page-9-17). We stack a frozen **960**

Table 5: Label distribution across probing tasks. Anc: Ancestor; Nod: Node type; Par: Parent predecessor; Pos: Position; Sib: Sibling; Str: Structural; Tre: Tree depth.

Training						
Batch size	4 (VR), 64 (AT)					
Epochs	20					
Patience	10					
Optimization						
Algorithm	Adam (Kingma and Ba, 2015)					
β_1, β_2	0.9, 0.999					
F	10^{-8}					
Weight decay	0.01					
Learning rate	10^{-3} (LED), 10^{-1} (LongT5)					

Table 6: Vanilla and random (VR), and atomic (AT) configuration hyperparameters.

pre-trained Transformer model with an endpoint **961** span extractor from AllenNLP, extracting and con- **962** catenating the first and last token of a given span. **963** Our hyperparameters are described in Tab. [6.](#page-13-1) **964**

Layer utilization. The layer utilization shown **965** in Fig. [7](#page-14-1) reveals differences between the probed **966** models and their controls. For LED, the vanilla con- **967** figuration shows a more uniform layer utilization **968** compared to the control configurations. The atomic **969** control puts more weight on the last layer for all **970** probes except node type and tree depth. **⁹⁷¹** For LongT5, both vanilla and atomic put all weight **972** on the last layer. For LED and LongT5, the ran- **973** dom control mostly uses the first layer, which has **974** also been observed in other works [\(Voita and Titov,](#page-11-13) **975** [2020\)](#page-11-13). The random control relies solely on the **976** input embeddings, as there is no additional infor- **977** mation in the Transformer layers. Input words such **978** as "Introduction" and the number of tokens in a **979** text node can be used to infer the node type. Node **980** type and word overlaps between two nodes can **981** give hints to the relation between two nodes. With **982** LongT5, the intermediate layers are not used at all. **983**

As the atomic control cannot compare the posi- **984** tion embeddings of different nodes, it makes full **985** use of the contextualization through the entire for- **986** ward pass. To solve the node type task, the **987** length of a node provides useful information. It **988** is retained in the atomic position embeddings, ex- **989** plaining the more uniform layer utilization on this **990** probe. The random control puts most weight on **991** the the first layer, which has also been observed **992** in other works [\(Voita and Titov,](#page-11-13) [2020\)](#page-11-13). It relies **993** on the input embeddings, as there is no additional **994** information in the Transformer layers. **995**

Figure 7: Layer utilization in probing of the vanilla LED and LongT5 models.

tok-type	3K
emb-type	3K
tok-depth	15K
emb-depth	15K

Table 7: Number of added parameters in structure infusion

996 B.3 Structure Infusion

 Embeddings. Structural embeddings are added to the token embeddings of each token in a node (including special tokens) before the first encoder self-attention layer (Fig. [4\)](#page-4-2). They were initialized according to a Gaussian distribution with mean 0 and standard deviation 0.0305 (LED) and 4.875 (LongT5). Standard deviation for LED was chosen to be the same as the standard deviation of the abso- lute linear position embeddings matrix. As LongT5 does not have absolute position embeddings, the standard deviation for structural embedding initial- ization was chosen to result in the same ratio of token embedding standard deviation to structural embedding standard deviation as for LED.

 Special tokens. Special tokens are prepended to the tokens of the respective node, lead- ing to an increase in total sequence length (Fig. [4\)](#page-4-2). They were initialized using the resize_token_embeddings() function in the model implementation.

 Number of added parameters. For the num- ber of added parameters for each infusion config- uration see Tab. [8.](#page-14-2) Each special token and each 1020 embedding adds d_{model} parameters to a model $(d_{LED} = d_{LongT5} = 768)$. There were 4 structural tokens / embeddings and 20 node depth tokens / embeddings.

Table 8: Pre-training (PT) and fine-tuning (FT) hyperparameters. *: Mean noise span length is chosen uniformly from the given values for each input sequence. [1] [Loshchilov and Hutter](#page-10-19) [2019](#page-10-19)

B.4 Pre-Training 1024

All structure infused models and baselines were 1025 pre-trained on the respective probing or evalu- **1026** ation dataset using a "T5-style" denoising task. **1027** Noise was added to the model input using **1028** [c](#page-10-16)ode provided by the authors of the T5 [\(Raf-](#page-10-16) **1029** [fel et al.,](#page-10-16) 2020) paper^{[14](#page-14-3)}, which replaces spans 1030 of tokens in the input with numbered mask to- **1031** kens. The mask tokens were initialized using the **1032** resize_token_embeddings() function in **¹⁰³³** the model implementation. Masking is controlled **1034** by two hyperparameters: *noise density*, the propor- **1035** tion of masked tokens in the input, and *mean noise* **1036** *span length*. We chose the noise density as 3%, the **1037**

¹⁴[https://github.com/google-research/](https://github.com/google-research/text-to-text-transfer-transformer) [text-to-text-transfer-transformer](https://github.com/google-research/text-to-text-transfer-transformer)

1054

1038 mean noise span length was uniformly chosen for **1039** each input sequence from 4, 8 or 12 tokens.

 The model is trained with a cross entropy loss to generate each mask token followed by the to- kens replaced by that mask, respecting the order of masked spans. To save computation, only one checkpoint was pre-trained for each combination of model, infusion configuration and dataset. This checkpoint was used in all replicates of a down-stream experiment.

1048 Training hyperparameters For training hyper-**1049** parameters, see Tab. [8.](#page-14-2)

 The only optimized hyperparameter is the learn- ing rate, which was done by grid search with the respective non-pretrained vanilla configuration on the QASPER dataset.

1055 B.5 Downstream Tasks

1056 B.5.1 QASPER

 Dataset conversion. Each entry in the QASPER dataset [\(Dasigi et al.,](#page-9-1) [2021\)](#page-9-1) consists of a paper title, abstract, full text in the form of a list of sections with section name and corresponding paragraphs, a list of figures and tables, as well as a list of ques- tions, answers and evidence. We converted the QASPER dataset into the Intertext Graph (ITG) format [\(Kuznetsov et al.,](#page-10-5) [2022\)](#page-10-5) creating a node for the title, abstract, each section title and each paragraph, as well as figures and tables. We added an additional abstract node with the content "Abstract" to serve as the parent for the abstract **1069** text.

 All answer types (extractive, abstractive, yes/no, unanswerable) were mapped to a single reference answer string for each question as done by the dataset authors. The provided evidence strings were mapped to the ITG nodes through string matching, which which was successful for 99.35% of evidence pieces from the original dataset. For 0.41%, there was no match, and for 0.24% there were multiple matches, which were discarded. Questions, answers and evidence are stored in the ITG metadata. We follow the original data splits, resulting in 888 train, 281 validation and 416 test documents.

 Model input. For LED, model input was formed as "<s> [question] </s> [document]". For LongT5, the initial <s> token was not used, as it is not pre-trained with this token. Figures and tables were discarded for model input. **1087**

Evaluation. QASPER evaluation was imple- **1088** mented by adapting the evaluation script provided 1089 by the creators of the dataset^{[15](#page-15-1)}. If there are mul- 1090 tiple reference answers to a question, the answer **1091** that results in the highest score is chosen as the **1092** gold standard. Answer generation is evaluated with **1093** [a](#page-11-14) token-level F1 score as in SQuAD [\(Rajpurkar](#page-11-14) **1094** [et al.,](#page-11-14) [2016\)](#page-11-14). Evidence selection is evaluated with **1095** a node-level F1 score. **1096**

Answer generation. Answers were generated **1097** with beam search, using 4 beams, length penalty 1098 1.0 and a maximum generated length of 100 tokens. **1099**

Evidence selection. Evidence selection was im- **1100** plemented as paragraph classification. There can be **1101** multiple evidence paragraphs for a question. The **1102** final encoder hidden state h of the first token of **1103** each paragraph node in a document is used as **¹¹⁰⁴** the representation for the paragraph. This vector **1105** is passed through a fully connected linear layer **1106** W_1 followed by a tanh nonlinearity and a linear 1107 layer W_2 projecting to the score vector $s \in \mathbb{R}^2$ for 1108 evidence and no-evidence. **1109**

$$
s = W_2 \tanh(W_1 h), W_1 \in \mathbb{R}^{d \times d}, W_2 \in \mathbb{R}^{d \times 2}
$$
\n(1)

Fine-tuning. Models pre-trained as described 1111 above on the QASPER train documents were fine- **1112** tuned on with the hyperparameters given in Tab. [8.](#page-14-2) 1113 Answer generation and evidence selection were **1114** trained with cross entropy loss: **1115**

$$
\mathcal{L} = w_A \mathcal{L}_{Answer} + w_E \mathcal{L}_{Evidence} \qquad (2) \qquad 1116
$$

(1) **1110**

For LED and LongT5 the loss weights were set to 1117 $w_A = w_E = 0.5$. The checkpoint with the best 1118 score on the dev set was used for evaluation. **1119**

B.5.2 Evidence Inference 1120

Dataset conversion. Evidence Inference 2.0 **1121** [\(DeYoung et al.,](#page-9-6) [2020\)](#page-9-6) is provided as sets of arti- **1122** cles, prompts and labels with evidence. The article **1123** full texts are provided as plain text files and NXML **1124** files following the PubMed DTD schema^{[16](#page-15-2)}. We 1125 used the parser from the dataset creators^{[17](#page-15-3)} to parse **1126**

```

download/
```
¹⁷[https://github.com/jayded/](https://github.com/jayded/evidence-inference)

[evidence-inference](https://github.com/jayded/evidence-inference)

¹⁵[https://github.com/allenai/](https://github.com/allenai/qasper-led-baseline)

[qasper-led-baseline](https://github.com/allenai/qasper-led-baseline)

 the NXML files, and converted the output to the ITG format. We added an additional abstract node with the content "Abstract" to serve as the parent for the abstract text.

 Evidence annotations are given as character off- sets pertaining to the articles in plain text format. We transform this span selection problem to a node classification problem by mapping evidence strings to ITG nodes. Evidence text at a given offset is extracted from a text file and then matched against **ITG** nodes using fuzzysearch^{[18](#page-16-1)}. Full string match- ing resulted in low recall, because of small dif- ferences between the plain text files and NXML files. For 92.03% of evidence spans, we find ex- actly one ITG node, for 5.10% we find no node, and for 2.07% we find more than one node, which are discarded. The prompts, labels and evidence for a document are stored in the ITG metadata. We follow the original data splits, resulting in 3562 train, 443 validation and 449 test documents.

 Model input. For LED, model input was formed as "<s> With respect to [outcome], characterize the reported difference between patients receiving [intervention] and those receiving [comparator]. </s> [document]". For LongT5, the initial <s> token was not used, as it is not pre-trained with this token.

 Evaluation. Evidence Inference classification is evaluated with macro F1 score. Evidence selection is evaluated with a node-level F1 score. If there are multiple annotations to a prompt, the annotation that results in the highest score is chosen. We chose to implement the evaluation similar to QASPER evaluation for consistency, and thus different from the implementation by the creators of the dataset. The main differences are (1) the conversion of ev- idence selection to a node classification task and (2) choosing the classification annotation that re- sults in the highest score, where in the original implementation the class with the highest number of annotations is chosen as the gold standard.

 Classification. To get the class of a prompt- document pair, a vector representation v of the document is passed through a fully connected layer M_1 , followed by a tanh nonlinearity and a linear

$$
layer M_2 projecting to the score vector l \in \mathbb{R}.
$$

$$
l = M_2(\tanh(M_1(v))), \ M_1 \in \mathbb{R}^{d \times d}, \ M_2 \in \mathbb{R}^{d \times 3}
$$
\n(3)

For LED, v was chosen as the final encoder hidden 1176 state of the initial $\langle s \rangle$ token, because it has global 1177 attention. As LongT5 does not have configurable **1178** global attention, a dummy $\langle \rangle$ s token was input 1179 to the decoder, which has full cross attention over **1180** the input document. The final decoder hidden state **1181** of this token served as v for LongT5. **1182**

Evidence selection. Evidence selection was im- **1183** plemented as for QASPER ([§B.5.1\)](#page-15-4). **1184**

Fine-tuning. Models pre-trained as described 1185 above on the Evidence Inference train documents **1186** were fine-tuned with the hyperparameters given in 1187 Tab [8.](#page-14-2) Classification and evidence selection were **1188** trained with cross entropy loss: **1189**

$$
\mathcal{L} = w_C \mathcal{L}_{Classification} + w_E \mathcal{L}_{Evidence} \qquad (4) \qquad 1190
$$

For LED, the loss weights were set to $w_C = 1191$ $w_E = 0.5$. For LongT5, they were set to $w_C = 1192$ 0.25, $w_E = 0.75$. The checkpoint with the best 1193 score on the dev set was used for evaluation. **1194**

B.6 Computation **1195**

Experiments were performed on NVIDIA A100, 1196 A180 and A6000 GPUs. Depending on the GPU **1197** size and speed, pre-training, probing (all 7 tasks) 1198 and downstream task experiments took 1-2 days. **1199** Estimating an average of 1.5 days per experiment, **1200** the total number of GPU days is 264 (26 probing **1201** runs, 30 pre-training runs, 120 downstream fine- **1202** tuning runs). **1203**

B.7 Use of AI Assistants in Development 1204

Some of the code for the structure infusion frame- **1205** work was developed with assistance from GitHub **1206** Copilot^{[19](#page-16-2)}. . **1207**
