Paper under double-blind review

Abstract

A prevalent assumption regarding real-world data is that it lies on or close to a low-dimensional manifold. When deploying a neural network on data manifolds, the required size, i.e., the number of neurons of the network, heavily depends on the intricacy of the underlying latent manifold. While significant advancements have been made in understanding the geometric attributes of manifolds, it's essential to recognize that topology, too, is a fundamental characteristic of manifolds. In this study, we investigate network expressive power in terms of the latent data manifold. Integrating both topological and geometric facets of the data manifold, we present a size upper bound of ReLU neural networks.

022 1 INTRODUCTION

The expressive power of deep neural networks (DNNs) is believed to play a critical role in their astonishing performance. Despite a rapidly expanding literature, the theoretical under-025 standing of such expressive power remains limited. The well-known universal approximation 026 theorems (Hornik, 1989; Cybenko, 1989; Leshno et al., 1993; Hanin, 2017) guarantee that 027 neural networks can approximate vast families of functions with an arbitrarily high accuracy. 028 However, the theoretical upper bound of the size of such networks is rather pessimistic; it is 029 exponential to the input space dimension. Indeed, these bounds tend to be loose, because the analyses are often oblivious to the intrinsic structure of the data. Real-world data such as images are believed to live in a manifold of a much lower dimension (Roweis & Saul, 032 2000; van der Maaten & Hinton, 2008; Jolliffe & Cadima, 2016). Such manifold's structure can be used to achieve better bounds of network size. It has been shown that the network 033 size can be bounded by exponential of the manifold's intrinsic dimension rather than the 034 encompassing input space dimension (Chen et al., 2019; Schmidt-Hieber, 2019).

However, the intrinsic dimension is only a small part of the manifold's property. It is natural
to ask whether other properties of the manifold, such as topology and geometry, may lead to
improved bounds. Safran & Shamir (2016) demonstrate that to approximate the indicator
function of a *d*-dimensional ball, one only needs a network of size quadratic to *d*. However,
this work assumes a rather simplistic input. To extend to a more general setting, one needs
to incorporate the topology and geometry of the manifold into the analysis.

Early research has probed the geometry and topology of manifolds. Notably, Federer (1959);
Amenta & Bern (1998) introduce a pivotal curvature measure, which adeptly captures the
global geometric nuances of manifolds and has been embraced in manifold learning studies
(Narayanan & Niyogi, 2009; Narayanan & Mitter, 2010; Ramamurthy et al., 2019). On the
topological front, descriptors like *Betti numbers* have been formalized in the language of
algebraic topology to characterized the numbers of connected components and holes of a
manifold (Hatcher, 2002; Bott et al., 1982; Munkres, 2018; Rieck et al., 2019). In their
seminal work, Niyogi et al. (2008) integrate manifold's geometry and topology, setting forth
conditions for topologically faithful reconstructions grounded in geometric metrics.

With the advent of the deep learning era, there has been a burgeoning interest in discerning
the interplay between network size and manifold's intrinsic structural attributes. Existing
studies (Dikkala et al., 2021; Schonsheck et al., 2019) bound network size with the geometry
of manifolds. However, a theoretical framework that successfully integrates network size and

topological traits has not yet been developed. This is a missed opportunity. The topological complexity of manifolds plays a crucial role in the learning problem, particularly concerning network size. Empirical findings (Guss & Salakhutdinov, 2018; Naitzat et al., 2020) suggest that even with similar geometry, data with larger topological complexity requires a larger network. These empirical observations highlight the need for a theoretical analysis that examines how manifold topology and geometry interact with network size. Addressing this need poses a significant challenge, as incorporating topological descriptors into the current analytical framework is inherently difficult due to the discrete nature of topology.

062 In this paper, we address this gap by presenting an innovative theoretical framework that 063 integrates topology with neural network size. We tackle the challenge by first approximating a homeomorphism to disentangle the geometry and topology of a manifold. Notably, manifold 064 topology remains invariant under a homeomorphism. This allows us to simplify the geometric 065 complexity while maintaining the topological complexity. We then successfully represent 066 discrete topological complexity as a combination of the complexities of basic topological 067 shapes, thus overcoming the challenge posed by the discrete nature of topological descriptors. 068 The resulting upper bound is obtained by constructing a neural network that first learns a 069 low-dimensional embedding of the input manifold, followed by classification in the embedding 070 space. This approach aligns with modern neural network design principles. 071

Our theoretical result reveals for the first time how the data topology, as a global structural characterization of data manifold, affects the network expressiveness. The beauty of the theorem is that it explicitly bounds the network size with both topology and geometry, giving us insights as to how the two important manifold properties affect learning. To capture the manifold's topology, we use the classic *Betti numbers*, which measure the number of connected components and holes within the manifold. For geometric measure, we use the *reach* introduced by Federer (1959); Amenta & Bern (1998), describing the manifold's overall flatness. See Figure 1 for illustrations of these measures.

079 080 Our main theoretical result is summarized informally below; the formal version is presented in Theorem 2.

Main Theorem. (Informal) Let $\mathcal{M} \subset \mathbb{R}^D$ be a d-dimensional manifold $(d \leq D)$ from a family of thickened 1-manifold and has two classes. There exists a ReLU network classifier g with depth at most $O(\log \beta + \log \frac{1}{\tau})$ and size at most $O(\beta^2 + (\frac{1}{\tau})^{d^2/2})$, such that with large probability, the true risk of g is small. β is the sum of Betti numbers and $\frac{1}{\tau}$ is the inverse of reach.

According to our bound, the network size scales quadratically in terms of the sum of Betti numbers β . Conversely, in terms of $\frac{1}{\tau}$, it scales as $O\left(\left(\frac{1}{\tau}\right)^{d^2/2}\right)$. This bound reveals interesting insights. The growth of network size is only affected by Betti numbers quadratically. Meanwhile, the network size can be affected by condition number more significantly when the intrinsic manifold dimension is high. These insights can be the foundation for future development of tighter bounds, and potentially inspire new designs of network architectures that capitalize on data's intrinsic manifold structures.

Figure 1: Illustration of *Betti numbers* and *reach*. (a) A 2-manifold embedding in \mathbb{R}^3 with $\beta_0 = 1, \beta_1 = 0$. (b) A 2-manifold embedded in \mathbb{R}^3 with $\beta_0 = 1, \beta_1 = 3$. (c) A 1-manifold with large reach. (d) A 1-manifold with small reach, which is the radius of the dashed circle.

In the following section, we discuss related works and compare our derived bounds with
those previously established. In Section 3, we define the problem and introduce the concept
of the thickened 1-manifold family. At first glance, this family may appear overly restrictive;
however, we will explain why it actually represents a broad and versatile class of manifolds.
In Section 4, we present our theoretical findings, detailing the step-by-step derivation of
our bounds. Our results establish a new theoretical perspective that can stimulate further

exploration into the expressiveness of networks. Looking ahead, this theory could inform the
 design of more efficient neural networks by leveraging insights from manifold topology and
 geometry.

Network size with manifold geometry. Multiple studies have formulated network 115 size bounds across varied manifold learning contexts based on geometry. Schonsheck et al. 116 (2019) establish a bound of $O(LdD\epsilon^{-d-d^2/2}(-\log^{1+d/2}\epsilon))$ on the network size for manifold 117 reconstruction tasks. L is the covering number in terms of the injectivity radius, a geometric 118 property. They utilize an auto-encoder, denoted as $D \circ E$, for the reconstruction of a manifold. 119 Both the encoder E and the decoder D are designed to function as homeomorphisms. As a 120 result, the overarching objective is the construction of a homeomorphism within the same 121 space, which elucidates the absence of topological considerations in their outcomes. Our 122 findings include not only the homeomorphism but also the classification network, with the 123 latter being influenced by the manifold's topology. Chen et al. (2019) demonstrate the existence of a network of size $O(\epsilon^{-d/n} \log \frac{1}{\epsilon} + D \log \frac{1}{\epsilon} + D \log D)$ that can approximate any smooth real function supported on a compact Riemannian manifold. In this context, n124 125 denotes the order of smoothness of the function. Their primary objective is to illustrate that, 126 in manifold learning, the manifold dimension chiefly determines network size, with only a 127 marginal dependence on the ambient dimension. Moreover, their smoothness assumption 128 is inapplicable to classification tasks, where the target function lacks continuity. Yet, 129 the interplay between manifold properties and their impact on network size in manifold 130 classification largely remains unexplored. 131

Classifier learned on manifold. Dikkala et al. (2021) investigate network size in classification contexts. However, their foundational assumption is that a manifold's essence can be 133 distilled into just two parameters: a centroid and a surrounding perturbation. They further 134 assume there is a sensitive hashing property on manifolds. These assumptions are quite 135 constrained, might not align with real-world complexities, and also overlooks the intrinsic 136 properties of the manifold. Nevertheless, the aforementioned studies predominantly concen-137 trate on network size and geometric traits, neglecting the equally critical role of topological 138 features. Buchanan et al. (2021) establish a lower bound on the size of classifiers for inputs 139 situated on manifolds. However, their theoretical framework is restricted to smooth, regular 140 simple curves; it fails to account for complex manifold structures. Guss & Salakhutdinov 141 (2018) provide empirical evidence showing that classifiers, when trained on data with higher 142 Betti numbers, tend to have slower convergence rates. They also highlight that with rising topological complexity, smaller networks face challenges in effective learning. These findings 143 underscore the need for a more comprehensive theoretical understanding. 144

145 There are some intriguing studies not primarily centered on manifold learning. Specifically, 146 Bianchini & Scarselli (2014) establish a bound for the Betti number of a neural network's 147 expression field based on its capacity. Nevertheless, their proposed bound is loose, and it exclusively addresses the regions a network can generate, neglecting any consideration 148 of input manifold. Safran & Shamir (2016) explore the challenge of approximating the 149 indicator function of a unit ball using a ReLU network. While their primary objective is to 150 demonstrate that enhancing depth is more effective than expanding width, their approach 151 has provided valuable insights. Naitzat et al. (2020) empirically examines the evolution of 152 manifold topology as data traverses the layers of a proficiently trained neural network. We 153 have adopted their concept of topological complexity. A number of studies, such as those by 154 Hanin & Rolnick (2019) and Grigsby & Lindsey (2022), concentrate on exploring the potential 155 expressivity of neural networks. However, these works primarily focus on the network's 156 inherent capabilities without extensively considering the characteristics of the input data. 157 Theoretically, Birdal et al. (2021); Andreeva et al. (2024) propose a persistent homology 158 generalization bound that accounts for the topology of the training trajectory. They propose a comprehensive metric that encompasses the neural network, optimization process, and 159 network activations. In contrast, our work focuses specifically on approximating the indicator 160 function of the data manifold using a neural network and studying the relationship between 161 neural network size and the properties of the data manifold.

⁶² 3 Preliminaries

163

Topological Manifolds. In this paper, we focus on a specific class of manifolds called the *thickened 1-manifold family*, which are derived from operations on 1-manifolds. To lay the groundwork, we begin with the concept of a manifold. An n-dimensional manifold is a topological space where every point has a neighborhood that is homeomorphic (topologically equivalent) to \mathbb{R}^n . And an n-manifold with boundary allows for points that have neighborhoods homeomorphic to the half-space $\mathbb{R}_{\geq 0} \times \mathbb{R}^{n-1}$. For example, a circle (s^1) is a 1-manifold without boundary, known as a closed manifold, while a line segment (I^1) is a 1-manifold with boundary.

172 Thickened 1-manifold. Our manifolds of interest are those obtained through operations on 1-manifolds, particularly when they are "thickened" to higher dimensions. Specifically, we 173 consider *d*-thickened 1-manifolds, which are (d + 1)-dimensional manifolds homeomorphic to 174 $\mathcal{M}^1 \times B^d$, where \mathcal{M}^1 is a compact 1-manifold (with or without boundary), and B^d denotes 175 a d-dimensional closed ball. Figure 2 illustrates the 1-thickened 1-manifold. According to 176 the classification theorem for 1-manifolds, \mathcal{M}^1 is homeomorphic to either a closed interval 177 I^1 or a circle S^1 . Consequently, a 1-thickened 1-manifold is homeomorphic to either $I^1 \times B^1$ 178 or $S^1 \times B^1$. 179

Connected Sum and Disjoint Union. To construct more complex manifolds from simpler ones, we utilize operations such as the connected sum and disjoint union. The connected 181 sum of two closed manifolds \mathcal{M} and \mathcal{N} , denoted $\mathcal{M} \# \mathcal{N}$, is formed by removing a small 182 open ball from each manifold and then gluing them together along the resulting boundary 183 sphere. The disjoint union $\mathcal{M} \sqcup \mathcal{N}$ combines two manifolds by considering them together 184 without connecting them. These operations yield new compact manifolds that combine the 185 topological features of the original manifolds. Although the connected sum of thickened 1-manifolds differs from the standard definition of the connected sum for closed manifolds 187 mentioned earlier, we utilize the fact that the boundary $\partial \mathcal{M}$ of a thickened 1-manifold \mathcal{M} is 188 a closed manifold. The connected sum of two thickened 1-manifolds is defined by performing 189 the connected sum on their boundaries and extend the gluing to the interiors of identifying 190 corresponding points in the neighborhoods adjacent to the removed sphere. The formal definition of connected sum is provided in section A.1. Figure A.1 illustrates the connected 191 sum between thickened 1-manifolds. 192

With the tools defined above, we can now define the thickened 1-manifold family, which is the class of manifolds we will study in this paper.

195 **Definition 1** (Thickened 1-Manifold Family). Let \mathcal{M}^1 represent a compact 1-manifold (with or without boundary). A d-thickened 1-manifold is a (d + 1)-manifold homeomorphic to $\mathcal{M}^1 \times B^d$. The family of d-thickened 1-manifolds, denoted by \mathbb{M} , includes all such manifolds obtained via finite operations of connected sum and disjoint union.

Betti numbers. We employ *Betti number* $\beta_k(\mathcal{M})$ to quantify topology of a manifold \mathcal{M} . k 200 is the dimension of that Betti number. 0-dimension Betti number $\beta_0(\mathcal{M})$ is the number of 201 connected components in \mathcal{M} , and $\beta_k(\mathcal{M})$ $(k \geq 1)$ can be informally described as the number 202 of k-dimensional holes. 1-dimensional hole is a circle and 2-dimensional hole is a void. For 203 the sake of coherence, we defer the formal definition of Betti numbers to Appendix A.1. 204 Following Naitzat et al. (2020), we utilize the total Betti number of \mathcal{M} as its topological 205 complexity. The topological complexity we employ here is the topological complexity of data 206 manifolds, instead of the topological complexity of neural networks used in Andreeva et al. 207 (2024).

208 **Definition 2** (Topological Complexity). \mathcal{M} is a d-dimensional manifold. $\beta_k(\mathcal{M})$ is the 209 k-dimensional Betti number of \mathcal{M} . The topological complexity is defined as

210

199

211

212 213 $\beta(\mathcal{M}) = \sum_{k=0}^{d-1} \beta_k(\mathcal{M}).$ (1)

Reach and conditional number. We then introduce metrics that encapsulate these geometric properties. For a compact manifold \mathcal{M} , the reach τ is the largest radius that the open normal bundle about \mathcal{M} of radius τ is embedded in \mathbb{R}^d , i.e., no self-intersection.

Figure 2: An illustration of the 1-thickened 1-manifold in 2D space. The top row shows a manifold that has the same homotopy type as a closed interval I^1 , while the bottom row shows a manifold that is homotopy equivalent to a circle S^1 . The 1-thickened 1-manifold family contains all manifolds that can be obtained through the disjoint union and connected sum of these manifolds.

Definition 3 (Reach and Condition Number). For a compact manifold $\mathcal{M} \subset \mathbb{R}^D$, let

$$G = \{ \mathbf{x} \in \mathbb{R}^{D} | \exists \mathbf{p}, \mathbf{q} \in \mathcal{M}, \mathbf{p} \neq \mathbf{q}, ||\mathbf{x} - \mathbf{p}|| = ||\mathbf{x} - \mathbf{q}|| = \inf_{\mathbf{y} \in \mathcal{M}} ||\mathbf{x} - \mathbf{y}|| \}.$$
 (2)

241 The reach of \mathcal{M} is defined as $\tau(\mathcal{M}) = \inf_{\mathbf{x} \in \mathcal{M}, \mathbf{y} \in G} ||\mathbf{x} - \mathbf{y}||$. The condition number $\frac{1}{\tau}$ is 242 the inverse of the reach.

Niyogi et al. (2008) prove that the condition number controls the curvature of the manifold at every point. A modest condition number $1/\tau$ signifies a well-conditioned manifold exhibiting low curvature.

Problem setup. In this paper, we examine the topology and geometry of manifolds in the classification setting. We have access to a training dataset $\{(\mathbf{x}_i, y_i) | \mathbf{x}_i \in \mathcal{M}, y_i \in [L]\}_{i=1}^n$, where $\mathcal{M} = \bigsqcup_{l=1}^{L} \mathcal{M}_l$. Each sample is drawn i.i.d. from a mixture distribution μ over Ldisjoint manifolds with the corresponding label. For the simplification of notation, we build our theory on binary classification. It can be extended to multi-class without efforts in a one-verses-all setting. In binary case, the dataset is $\{(\mathbf{x}_i, y_i) | \mathbf{x}_i \in \mathcal{M}, y_i \in \{0, 1\}\}_{i=1}^n$, where $\mathcal{M} = \mathcal{M}_1 \sqcup \mathcal{M}_0 \in \mathbb{R}^D$. \mathcal{M}_1 and \mathcal{M}_0 are two disjoint d-dimensional manifolds representing two classes. The label y_i is determined by the indicator function

$$I_{\mathcal{M}_1}(\mathbf{x}) = \begin{cases} 1, & \mathbf{x} \in \mathcal{M}_1, \\ 0, & \text{otherwise.} \end{cases}$$
(3)

A neural network $h(\mathbf{x}) : \mathbb{R}^D \to [0, 1]$ approaches the classification problem by approximating the indicator function $I_{\mathcal{M}_1}(\mathbf{x})$. In the scope of this study, we focus on neural networks utilizing the ReLU (Rectified Linear Unit) activation function.

261 Definition 4 (Adapted from Arora et al. (2018)). A ReLU multi-layer feed-forward network **262** $h: \mathbb{R}^{w_0} \to \mathbb{R}^{w_{k+1}}$ with k+1 layers is defined as

$$h(\mathbf{x}) = h_{k+1} \circ h_k \circ \dots \circ h_1(\mathbf{x}),\tag{4}$$

265 where $h_i : \mathbb{R}^{w_{i-1}} \to \mathbb{R}^{w_i}, h_i(\mathbf{x}) = \sigma(W_i\mathbf{x} + b_i)$ for $1 \le i \le k$ are ReLU layers, and 266 $h_{k+1} : \mathbb{R}^{w_k} \to \mathbb{R}^{w_{k+1}}, h_{k+1}(\mathbf{x}) = W_{k+1}\mathbf{x} + b_{k+1}$ is a linear layer. σ is the ReLU activation 267 function. The **depth** of the ReLU network is defined as k + 1. The **width** of the ReLU 268 network is $\max\{w_1, \ldots, w_k\}$. The **size** of the ReLU network is $\sum_{i=1}^k w_i$.

The approximation error of a ReLU network is determined by the true risk.

230

243

255 256 257

263 264

269

237

270 **Definition 5** (Approximation Error). Let's consider the indicator function $I_{\mathcal{M}_1}$ for a 271 manifold \mathcal{M}_1 in a binary classification problem where $\mathcal{M} = \mathcal{M}_1 \sqcup \mathcal{M}_0$. A neural network 272 operates as a function $h(\mathbf{x}) : \mathcal{M} \to \mathbb{R}$. The approximation error of the neural network h is 273 then defined as:

True Risk:
$$R(h) = \int_{\mathcal{M}} (h - I_{\mathcal{M}_1})^2 \mu(\mathbf{x}) d\mathbf{x}.$$
 (5)

 μ is any continuous distribution over \mathcal{M} .

4 MAIN RESULTS

In this section, we explore how the topology of manifolds influence network size in classification 281 scenarios. Our results, derived methodically through construction, follow two steps. First, we 282 approximate a homeomorphism between the input manifold and a latent one; second, we carry 283 out classification within this latent manifold. This latent manifold is designed to have simple 284 geometric features, akin to those found in spheres and tori, while retaining the intrinsic 285 topological characteristics of the original manifold. By design, the first phase is purely 286 geometric, as the topological traits remain unaltered, while the subsequent classification phase is predominantly topological. Consequently, the required network size can be delineated 287 into two distinct parts. We employ *Betti numbers* and the *condition number* as metrics 288 to gauge topological and geometric complexities, respectively. Specifically, Betti numbers 289 quantify the number of connected components and holes within the manifold, whereas the 290 condition number characterizes the manifold's overall curvature. 291

4.1 Complexity Arising from Topology

To focus on the topological aspects rather than the geometric intricacies of the manifold, our attention shifts to the elemental shapes that typify the thickened 1-manifold collection. Among these shapes are the *d*-dimensional balls, denoted as $B_r^d(\mathbf{c})$, and the solid *d*-tori, represented by $T_{r,R}^d$. The *d*-dimensional ball, $B_r^d(\mathbf{c})$, is characterized by a radius *r* and is centered at **c**, mathematically defined as

$$B_r^d(\mathbf{c}) = \left\{ \mathbf{x} \in \mathbb{R}^d : \|\mathbf{x} - \mathbf{c}\|_2 \le r \right\}.$$
(6)

On the other hand, the solid *d*-torus, $T_{r,R}^d$, embodies a genus-1 torus with a tunnel radius of r and a tunnel center radius of R, centered at **c**. Its formula is given by

306

299

300

301

292

293

274 275 276

277 278

279

$$T_{r,R}^{d}(\mathbf{c}) = \left\{ \mathbf{x} \in \mathbb{R}^{d} : (x_{d} - c_{d})^{2} + \left(\sqrt{\sum_{i=1}^{d-1} (x_{i} - c_{i})^{2} - R} \right)^{2} \le r^{2} \right\}.$$
 (7)

It's pertinent to acknowledge that the general structure of a *d*-torus becomes significantly more complex as *d* increases. The provided equation for $T_{r,R}^d$ represents only one of its potential configurations. Nevertheless, this depiction suffices within the context of the thickened 1-manifold ensemble.

Lemma 1 (Topological Representative). Let $\mathcal{M} \subset \mathbb{M}$ be a d-dimensional manifold from the thickened 1-manifold family. There exist a set of m_1 d-balls $\mathcal{B} = \{B_{r_i}^d(\mathbf{c}_i)\}_{i=1}^{m_1}$ and a set of m_2 solid d-tori $\mathcal{T} = \{T_{r_i,R_i}^d(\mathbf{c}_i)\}_{i=1}^{m_2}$, such that \mathcal{M} is homeomorphic to the union $(\bigcup_{B\in\mathcal{B}}B) \cup (\bigcup_{T\in\mathcal{T}}T)$, where $m_1 + m_2 \leq \beta(\mathcal{M})$ is a constant integer. We term $\mathcal{M}' =$ $(\bigcup_{B\in\mathcal{B}}B) \cup (\bigcup_{T\in\mathcal{T}}T)$ as the **topological representative** of \mathcal{M} .

Given the classification theorem of 1-manifolds, compact 1-manifolds without boundary are homeomorphic to a circle, while compact 1-manifolds with boundary are homeomorphic to a closed interval. Therefore, the thickened 1-manifolds are homeomorphic to either a solid torus or a ball. Our preliminary analysis focuses on the network size associated with d-balls and d-tori. Using this as a foundation, we then explore how various topological configurations of thickened 1-manifold impact the size of neural networks. Proposition 1 determines the network size required to approximate a \mathbb{R}^d ball. While the original result is found in Safran & Shamir (2016), our study utilizes fewer parameters and offers a different way to approximate the threshold function. Proposition 2 outlines a network size bound for
 the approximation of a solid torus.

Proposition 1 (Approximating a \mathbb{R}^d Ball, adapted from Theorem 2 in Safran & Shamir (2016)). Given $\epsilon > 0$, there exists a ReLU network $h : \mathbb{R}^d \to \mathbb{R}$ with 3 layers and with size at most $4d^2r^2/\epsilon + 2d + 2$, which can approximate the indicator function $I_{B_r^d}$ within error $R(h) \leq \epsilon$ for any continuous distribution $\mu(\mathbf{x})$.

Proposition 2 (Approximating a Solid Torus). Given $\epsilon > 0$, there exists a ReLU network $h: \mathbb{R}^d \to \mathbb{R}$ with 5 layers and with size at most $\frac{2d}{\epsilon}(4(d-1)(R+r)^2 + 8r^2 + \frac{r}{\sqrt{R-r}}) + 9$, which can approximate the indicator function $I_{T_{r,R}^d}$ within error $R(h) \leq \epsilon$ for any continuous distribution $\mu(\mathbf{x})$.

335 Both proofs begin by expressing the indicator function as a composition of truncated power 336 functions. Each truncated power function can be approximated by a piecewise linear function, which can be precisely represented by a ReLU layer. The composition of these power functions 338 is then thresholded, and this threshold function can also be approximated by another ReLU 339 layer. The overall approximation error is estimated across these two steps. Proposition 1 and 340 2 address the network size associated with approximating B_r^d and $T_{r,R}^d$. Detailed proofs can be 341 found in the Appendix A.3. Building on this, we can infer the network size for approximating 342 topological representatives by combining the complexities of approximating B_r^d and $T_{r,R}^d$ 343 with those of union operation. This consolidated insight is captured in Theorem 1. 344

Theorem 1 (Complexity Arising from Topology). Suppose \mathcal{M}' is the topological representative of d-manifold from the thickened 1-manifold family. Given $\epsilon > 0$, there exists a ReLU network $h : \mathbb{R}^d \to \mathbb{R}$ with depth at most $O(\log \beta)$ and size at most $O(\frac{d^2\beta^2}{\epsilon})$, that can approximate the indicator function $I_{\mathcal{M}'}$ with error $R(h) \leq \epsilon$ for any continuous distribution μ over \mathbb{R}^d . β is the topological complexity of \mathcal{M}' .

Since a topological representative is the union of balls and solid tori, the overall network size is computed by summing the network sizes required to approximate the balls and tori, along with the network size needed for the union operations. The detailed proof can be found in Appendix A.4. This theorem offers an upper bound on the network size required to approximate the indicator function of a topological representative. It is important to note that this captures the full range of complexities arising from the topology of a manifold $\mathcal{M} \in \mathbb{M}$, given that \mathcal{M} and \mathcal{M}' are homeomorphic. To the best of our knowledge, this is the first result bounding neural network size in terms of a manifold's Betti numbers.

358 359

4.2 Overall Complexity

360 For general manifolds in $\mathcal{M} \in \mathbb{M}$, due to their inherent complexity, often defy explicit 361 expression. This hinders the direct use of function analysis for approximating their indicator 362 functions, as was done in previous studies. To tackle this issue, we construct a homeomor-363 phism, a continuous two-way transformation, between \mathcal{M} and its corresponding topological 364 representative \mathcal{M}' . This method only alters the geometric properties, preserving the object's topological attributes. Therefore, the network size in approximating the indicator function 365 of \mathcal{M} is constructed by the approximation of the homeomorphism and the classification 366 of topological representatives. The network size of constructing the homeomorphism is 367 exclusively influenced by the geometric properties, whereas the network size of classifying 368 topological representatives pertains solely to topological properties. The latter we already 369 figured in previous section. This methodology enables us to distinguish the influence of 370 topology and geometry of manifold on classifiers. In this section, we aim to obtain the overall 371 network size for a classifier. 372

To build a homeomorphism from \mathcal{M} , we first need to recover the homology of \mathcal{M} . The subsequent proposition outlines a lower limit for the number of points essential to recover the homology of the initial manifold \mathcal{M} .

Proposition 3 (Theorem 3.1 in Niyogi et al. (2008)). Let \mathcal{M} be a compact d-dimensional submanifold of \mathbb{R}^D with condition number $1/\tau$. Let $X = \{\mathbf{x}_1, \mathbf{x}_2, .., \mathbf{x}_n\}$ be a set of n points drawn in i.i.d. fashion according to the uniform probability measure on \mathcal{M} . Let $0 < \epsilon < \frac{\tau}{2}$. Let $U = \bigcup_{\mathbf{x} \in X} B_{\epsilon}(\mathbf{x})$ be a corresponding random open subset of \mathbb{R}^{D} . Then for all

$$n > \lambda_1(log(\lambda_2) + log(\frac{1}{\delta})),$$

(8)

U is a ϵ -cover of \mathcal{M} , and the homology of U equals the homology of \mathcal{M} with high confidence (probability $> 1 - \delta$). Here

$$\lambda_1 = \frac{vol(\mathcal{M})}{(\cos^d \theta_1)vol(B^d_{\epsilon/4})} \text{ and } \lambda_2 = \frac{vol(\mathcal{M})}{(\cos^d \theta_2)vol(B^d_{\epsilon/8})},\tag{9}$$

 $\begin{array}{ll} 388 \\ \theta_1 = \arcsin(\epsilon/8\tau) \ and \ \theta_2 = \arcsin(\epsilon/16\tau). \ vol(B^d_{\epsilon}) \ denotes \ the \ d-dimensional \ volume \ of \\ 389 \end{array}$ $\begin{array}{ll} the \ standard \ d-dimensional \ ball \ of \ radius \ \epsilon. \ vol(\mathcal{M}) \ is \ the \ d-dimensional \ volume \ of \ \mathcal{M}. \end{array}$

This result stipulates a lower bound for the training set size necessary to recover the homology of the manifold, which is the foundation to learn the homeomorphism between a manifold $\mathcal{M} \in \mathbb{M}$ and its topological representative \mathcal{M}' . However, directly constructing this homeomorphism remains challenging. As a workaround, we develop a simplicial homeomorphism to approximate the genuine homeomorphism. Notably, this simplicial approach lends itself readily to representation via neural networks.

Combined with the topological representative classification network in Theorem 1, we can 397 construct a classification network for general manifolds in \mathbb{M} , as depicted in Figure 3. Initially, 398 we project \mathcal{M} to its simplicial approximation |K| using a neural network N_p . This is succeeded 399 by a network N_{ϕ} that facilitates the simplicial homeomorphism between |K| and |L|, the 400 latter being the simplicial approximation of the topological representative \mathcal{M}' . Finally, a 401 network h is utilized to classify between $|L_1|$ and $|L_0|$. Consequently, the network's size is 402 divided into two main parts: one focused on complexities related to geometric attributes and 403 the other concerning topological aspects. This distinction separates topology from geometry 404 in classification problems. 405

In Theorem 2, we design such a neural network based on this training set, ensuring that approximation errors are effectively controlled. The detailed proof is provided in Appendix A.5.
 Our proof strategy begins with the construction of a ReLU network, followed by an evaluation of the network's size. Subsequently, we place bounds on the involved approximation errors.

Figure 3: Construction of the network g. The network first learns a low-dimensional embedding and then performs classification in the embedding space. This paradigm mirrors the typical operation of deep networks. While the diagram illustrates only the process for the manifold of the positive class, the procedure for \mathcal{M}_0 mirrors this operation identically.

Theorem 2 (Main Theorem). Let $\mathcal{M} = \mathcal{M}_1 \sqcup \mathcal{M}_0 \subset \mathbb{R}^D$ be a d-dimensional manifold from the thickened 1-manifold family. \mathcal{M}_1 and \mathcal{M}_0 are two disjoint sub-manifolds of \mathcal{M} representing two classes. The condition number of \mathcal{M} is $\frac{1}{\tau}$ and the total Betti number of \mathcal{M}_1 is β . Given a training set $\{(\mathbf{x}_i, y_i) | \mathbf{x}_i \in \mathcal{M}, y_i \in \{0, 1\}\}_{i=1}^n$, where \mathbf{x}_i are sampled i.i.d. from \mathcal{M} by a uniform distribution, and $y_i = I_{\mathcal{M}_1}(\mathbf{x}_i)$. For any $\delta > 0$, if inequality (8) holds, then for any $\epsilon > 0$, there exists a ReLU network g with depth at most $O(\log \beta + d \log \frac{1}{\tau} + \log \log \frac{1}{\tau\delta})$ and size at most $O(\frac{d^2\beta^2}{\epsilon} + \tau^{-d^2/2} \log^{d/2} \frac{1}{\tau\delta} + D\tau^{-d} \log \frac{1}{\tau\delta})$, such that

$$R(g) \le \epsilon) > 1 - \delta, \tag{10}$$

where $R(g) = \int_{\mathcal{M}} (g - I_{\mathcal{M}_1})^2 \mu(\mathbf{x}) d\mathbf{x}$ with any continuous distribution μ .

Proof Sketch. Since $\mathcal{M} = \mathcal{M}_1 \sqcup \mathcal{M}_0$ is from thickened 1-manifold family, it has a topological representative $\mathcal{M}' = \mathcal{M}'_1 \sqcup \mathcal{M}'_0 \subset \mathbb{R}^d$, where \mathcal{M}'_1 and \mathcal{M}'_0 are topological representatives of \mathcal{M}_1 and \mathcal{M}_2 , respectively. The proof follows Figure 3, by first constructing simplicial approximations |K| and |L| of \mathcal{M} and \mathcal{M}' , respectively. Then we represent a simplicial homeomorphism $\phi: |K| \to |L|$ by a neural network N_{ϕ} , where K is constructed from \mathcal{M} and L from \mathcal{M}' . Built on the top of this, a projection from \mathcal{M} to its simiplicial approximation |K| is represented by another network N_p . The overall network can be constructed by $g = h \circ N_{\phi} \circ N_p$. The proof is completed by first constructing the network g, and then bounding the approximation error.

Upon examining the depth and size of the neural network, it becomes evident that the topological complexity, denoted by β , and the geometric complexity, symbolized by τ , are distinctly delineated. The topological complexity contributes $O\left(\frac{d^2\beta^2}{\epsilon}\right)$ to the overall network size. In contrast, geometry contributes $O\left(\tau^{-d^2/2}\log^{d/2}\frac{1}{\tau\delta} + D\tau^{-d}\log\frac{1}{\tau\delta}\right)$.

EXPERIMENTS (REBUTTAL MATERIAL)

Figure 4: Validation of topological complexity bound. We utilize manifolds characterized as solid genus-q tori, with q spanning from 1 to 10. For each torus, we consistently sample $q \times 10^4$ points from a surrounding bounding box that cover the torus. The labels for these points are generated using the indicator function of the solid torus. (a,b) are two examples of genus-q tori, but samples from the background class are not visualized in the graph. (c) showcases the linear regression results between the network size and the square of topological complexity. A 5-layer neural network with adaptive width is trained to fit tori of varying genus q. The width of the network is increased until the training accuracy can exceed 0.95when the MSE loss converges. This regression underscores a pronounced linear association between network size s and β^2 , with a correlation coefficient r = 0.9698.

In this section, we present numerical results that showcase our topological bound $O\left(\frac{d^2\beta^2}{\epsilon}\right)$ in fixed dimension. Even though this bound is derived through construction and serves as an upper limit, it is intriguing to discover that the bound is tight and can be readily observed in experimental settings. In practical scenarios, when training networks of varying sizes on data drawn from manifolds with different total Betti numbers β , and achieving the same error rate, we anticipate a linear relationship between the network size and β^2 .

We utilize manifolds characterized as solid genus-q tori, with q spanning from 1 to 10. Each genus-g torus is synthesized by overlapping two identical tori. For each torus, we consistently sample $g \times 10^4$ points from a surrounding bounding box. The labels for these points are generated using the indicator function of the solid torus.

For training, we deploy a 5-layer ReLU network, gradually increasing its width until the training accuracy surpasses 0.95. Figure 4c presents a regression line charting the relationship between network size and the squared topological complexity, β^2 . This regression underscores 486 a pronounced linear association between network size s and β^2 , with a correlation coefficient r = 0.9698.

506

6 CONCLUSION

In this study, we delved into the intricate relationship between network size, and both
geometric and topological characteristics of manifolds. Our findings underscored that while
many existing studies have been focused on geometric intricacies, it is important to also
appreciate the manifold's topological characteristics. These characteristics not only offer an
alternative perspective on data structures but also influence network size in significant ways.

Our proposed network size bounds represent theoretical upper limits, meaning that real-world
implementations may yield efficiencies beyond these confines. To attain a more direct and
refined theoretical bound, we may need more comprehensive descriptors of manifolds that go
beyond merely the Betti numbers and the condition number. We leave this exploration for
future work. We hope that our study acts as a catalyst for further research, pushing the
boundaries of manifold learning and its applications in modern AI systems.

650 In this section, we formally prove the theoretical findings presented in the primary manuscript. Initially, we utilize some necessary definitions and existing results. Then we prove the network 652 size bound for fundamental solid manifolds and general topological representatives.

654 A.1 Additional Definitions

The first definition is *Betti number*, which is a vital part of this paper. The k-th Betti 656 number is defined as the rank of k-th homology group. Therefore, we have to properly define 657 homology group first. Our definition follows Hatcher (2002) but is tailed for simplification. 658 We first define simplicial homology for simplicial complexes. (Actually for Δ -complexes, we 659 simplify it to avoid introducing Δ -complexes.) Then extend it to singular homology that can 660 be applied to manifolds. 661

Simplicial Homology. Let K be a simplicial complex, and let K^k be the set of all k-662 dimensional simplices in K. The set of K^k together with the field \mathbb{Z}_2 forms a group $C_k(K)$. It 663 is a vector space defined on \mathbb{Z}_2 with K^k as a basis. The element of $C_k(K)$ is called a k-chain. 664 Let $\sigma \in K^k$ be a k-simplex. The boundary $\partial_k(\sigma)$ is the collection of its (k-1)-dimensional 665 faces, which is a k-1-simplicial complex. The boundary operator is linear, i.e. 666

$$\partial_k(z_1\sigma_1 + z_2\sigma_2) = z_1\partial_k(\sigma_1) + z_2\partial_k(\sigma_2)$$

668 The boundary operator $\partial_k : C_k(K) \to C_{k-1}(K)$ introduces a chain complex

$$\cdots \to C_d \xrightarrow{\partial_d} C_{d-1} \xrightarrow{\partial_{d-1}} C_{d-2} \to \cdots \to C_0 \xrightarrow{\partial_0} \emptyset.$$

671 d is the maximum dimension of K. Ker ∂_k is the collection of k-chains with empty boundary 672 and Im ∂_k is the collection of (k-1)-chains that are boundaries of k-chains. Then we can define 673 the k-th homology group of the chain complex to be the quotient group $H_k = \operatorname{Ker} \partial_k / \operatorname{Im} \partial_{k+1}$. The k-th Betti number is defined by 674

$$\beta_k = \operatorname{rank} H_k.$$

Singular Homology. Given a topological space X, the k-th singular chain group $C_k(X)$ is defined as the free Abelian group generated by the continuous maps $\phi: K^k \to X$, where K^k is the standard k-simplex in \mathbb{R}^k . Each such map is referred to as a singular k-simplex in X.

A boundary operator $\partial_k : C_k(X) \to C_{k-1}(X)$ can be defined as:

$$\partial \phi = \sum_{i=0}^{n} (-1)^i \phi|_{[v_0, \cdots, \hat{v}_i, \cdots, v_n]}$$

where $\phi|_{[v_0, \dots, \hat{v}_i, \dots, v_n]}$ represents the restriction of σ to the *i*-th face of K^k .

686 The k-th singular homology group $H_k(X)$ is then represented as the quotient:

$$H_k(X) = \operatorname{Ker} \partial_k / \operatorname{Im} \partial_{k+1}.$$

The k-th Betti number is still defined as $\beta_k = \operatorname{rank} H_k(X)$. 689

690 Connected Sum of Thickened 1-Manifold. Let $\mathcal{M} = \mathcal{M}^1 \times B^d$ and $\mathcal{N} = \mathcal{N}^1 \times B^d$ be 691 two d-thickened 1-manifolds, where \mathcal{M}^1 and \mathcal{N}^1 are compact 1-manifolds (with or without boundary), and B^d is a d-dimensional closed ball. We define the connected sum $\mathcal{M} \# \mathcal{N}$ by 692 performing connected sum on their boundaries and then extend the gluing to the interior. 693 The process is defined as: 694

- 1. The connected sum of boundaries. The boundaries of \mathcal{M} and \mathcal{N} are closed manifolds, where $\partial \mathcal{M} = \mathcal{M}^1 \times S^{d-1}$ and $\partial \mathcal{N} = \mathcal{N}^1 \times S^{d-1}$. Two open neighborhoods $U \subset \partial \mathcal{M}$ and $V \subset \partial \mathcal{N}$ are removed from the boundaries. Then a homeomorphism $h: \partial U \to \partial \mathcal{N}$ ∂V is defined to match the resulting boundaries. Then glue $\partial \mathcal{M} \setminus U$ and $\partial \mathcal{N} \setminus V$ along ∂U and ∂V via h, forming $\partial(\mathcal{M} \# \mathcal{N})$.
- 700 2. Extend the gluing to the interiors of \mathcal{M} and \mathcal{N} by identifying corresponding points in the neighborhoods adjacent to U and V.

h(x) is a piece-wise linear function with m + 2 pieces. According to Lemma 2, there exists a 2-layer ReLU network with at most m + 1 pieces that can represent h(x). Proof done. \Box

A.3 Approximating Fundamental Solid Manifolds

758 Now we are in a good position to prove Proposition 1 and 2.

Proposition 1 (Approximating a \mathbb{R}^d Ball, adapted from Theorem 2 in Safran & Shamir (2016)). Given $\epsilon > 0$, there exists a ReLU network $h : \mathbb{R}^d \to \mathbb{R}$ with 3 layers and with size at most $4d^2r^2/\epsilon + 2d + 2$, which can approximate the indicator function $I_{B_r^d}$ within error $R(h) \le \epsilon$ for any continuous distribution $\mu(\mathbf{x})$.

Proof. We generally follow the original proof but derive a slightly different bound with
fewer parameters. The proof is organized by first using a non-linear layer to approximate a
truncated square function and then using another non-linear layer to approximate a threshold
function. Consider the truncated square function

$$(x;r) = \min\{x^2, r^2\}.$$
 (A.2)

Clearly l(x;r) is a Lipschitz function with Lipschitz constant 2r. Applying Lemma 6, we have a 2-layer ReLU network h_{11} that can approximate l(x;r) with

$$\sup_{x \in \mathbb{R}} \left| h_{11}(x) - l(x) \right| \le \epsilon_1, \tag{A.3}$$

with at most $2r^2/\epsilon_1 + 2$ nodes. Now for $\mathbf{x} \in \mathbb{R}^d$, let

$$h_1(\mathbf{x}) = \sum_{i=1}^d h_{1i}(x_i).$$
 (A.4)

Note that h_1 is also a 2-layer network because no extra non-linear operation is introduced in equation A.4, and has size at most $2dr^2/\epsilon_1 + 2d$. This can also be verified by Lemma 4. Let

$$L(\mathbf{x}) = \sum_{i}^{d} L(x_i; r), \tag{A.5}$$

and we have

763

768

772

775 776 777

780 781 782

783 784

789

790 791

798 799

800

$$\sup_{\mathbf{x}} \left| h_1(\mathbf{x}) - L(\mathbf{x}) \right| \le d\epsilon_1. \tag{A.6}$$

785 Let $\epsilon_1 = d\epsilon_1$, then h_1 has size at most $2d^2r^2/\epsilon_1 + 2d$. Although $L(\mathbf{x})$ is different from $\sum x_i^2$, 786 the trick here is to show $B_r^d = {\mathbf{x} : L(\mathbf{x}) \le r^2}$.

788 On the one hand, if $L(rvx) \leq r^2$, remember that

$$L(\mathbf{x}) = \sum_{i=1}^{a} \min\{x_1^2, r^2\} \le r^2.$$
(A.7)

792 This means for all $x_i, x_i \leq r^2$. Therefore, $L(\mathbf{x}) = \sum_{i=1}^d x_i^2$. On the other, $L(\mathbf{x}) > r^2$ only 793 happens when there exists a *i*, such that $x_i^2 > r^2$. Thus, $\mathbf{x} \notin B_r^d$. Consequently, one can 794 represent $I_{B_r^d}$ by $L(\mathbf{x}) \leq r^2$. 795

The next step towards this proposition is to construct another 2-layer ReLU network to threshold $L(\mathbf{x})$. Consider

$$f(x) = \begin{cases} 1, & x < r^2 - \delta, \\ \frac{r^2 - x}{\delta}, & x \in [r^2 - \delta, r^2], \\ 0, & x > r^2. \end{cases}$$
(A.8)

Note that f is a 3-piece piece-wise linear function that approximates a threshold function. According to Lemma 2, a 2-layer ReLU network h_2 with size 2 can represent f. The function $f \circ L(\mathbf{x})$ can then be estimated by a 3-layer network $h = h_2 \circ h_1$, whose size is $2d^2r^2/\epsilon_1 + 2d + 2$. The next step is to bound the error between h and $I_{B_r^d}$. We consider the L_2 -type bound $||h(\mathbf{x}) - I_{B_r^d}(\mathbf{x})||_{L_2(\mu)} = \int_{\mathbb{R}^d} (h(\mathbf{x}) - I_{B_r^d}(\mathbf{x}))^2 \mu(\mathbf{x}) d\mathbf{x}$. We divide the integral into two parts

807
$$||h(\mathbf{x}) - I_{B_r^d}(\mathbf{x})||_{L_2(\mu)}$$

808
809
$$\leq ||f \circ L(\mathbf{x}) - I_{B_r^d}(\mathbf{x})||_{L_2(\mu)} + ||f \circ L(\mathbf{x}) - h_2 \circ h_1(\mathbf{x})||_{L_2(\mu)}$$
(A.9)

$$= I_1 + I_2.$$

Since $\mu(\mathbf{x})$ is continuous, there exists δ such that

$$\int_{S_{\delta}} \mu(\mathbf{x}) d\mathbf{x} \le \epsilon_2. \tag{A.10}$$

 $S_{\delta} = \{ \mathbf{x} \in \mathbb{R}^d : r^2 - \delta \leq \sum_{i=1}^d x_i^2 \leq r^2 \}.$ Combine equation A.8 we have

$$I_{1} = \int_{\mathbb{R}^{d}} (f \circ L(\mathbf{x}) - I_{B_{r}^{d}}(\mathbf{x}))^{2} \mu(\mathbf{x}) d\mathbf{x}$$

$$= \int_{S_{\delta}} (f \circ L(\mathbf{x}) - I_{B_{r}^{d}}(\mathbf{x}))^{2} \mu(\mathbf{x}) d\mathbf{x}$$

$$= \int_{S_{\delta}} (f \circ L(\mathbf{x}) - 1)^{2} \mu(\mathbf{x}) d\mathbf{x}$$

$$\leq \int_{S_{\delta}} \mu(\mathbf{x}) d\mathbf{x}$$

$$\leq \epsilon_{2}.$$
(A.11)

The first inequality is because $f \in [0, 1]$, such that $(f \circ L(\mathbf{x}) - 1)^2 \leq 1$. The second part of the error can be easily bounded by its infinity norm.

$$I_{2} = ||f \circ L(\mathbf{x}) - h_{2} \circ h_{1}(\mathbf{x})||_{L_{2}(\mu)} \le ||f \circ L(\mathbf{x}) - h_{2} \circ h_{1}(\mathbf{x})||_{\infty} \le \epsilon_{1}.$$
 (A.12)

The last inequality is because h_2 is the exact representation of f, the error only occurs between $L(\mathbf{x})$ and h_1 . Combine A.11 and A.12, and let $\epsilon_1 = \epsilon_2 = \epsilon/2$, we have

$$||h(\mathbf{x}) - I(\mathbf{x})||_{L_2(\mu)} \le \epsilon.$$
(A.13)

The size of network h is then bounded by $4d^2r^2/\epsilon + 2d + 2$.

Proposition 2 (Approximating a Solid Torus). Given $\epsilon > 0$, there exists a ReLU network $h: \mathbb{R}^d \to \mathbb{R}$ with 5 layers and with size at most $\frac{2d}{\epsilon}(4(d-1)(R+r)^2+8r^2+\frac{r}{\sqrt{R-r}})+9$, which can approximate the indicator function $I_{T^d_{r,R}}$ within error $R(h) \leq \epsilon$ for any continuous distribution $\mu(\mathbf{x})$.

Proof. The proof is done by two steps. We first use layers to estimate a truncated function. Then estimate a threshold function by another layer.

Consider the truncated square function and root function,

$$l_1(x;\gamma) = \min\{x^2, \gamma^2\}, l_2(x;\gamma_1, \gamma_2) = \min\{\max\{\sqrt{x}, \gamma_1\}, \gamma_2\}, (\gamma_1 < \gamma_2).$$

The Lipschitz constants for l_1 and l_2 are 2γ and $\frac{1}{2\sqrt{\gamma_1}}$, respectively. By Lemma 6, there is a 2-layer ReLU network to approximate l_1 and l_2 with size $\lceil 4\gamma^2/\epsilon_1 \rceil + 1$ and $\lceil (\gamma_2 - 1) \rceil$ $(\gamma_1)/(2\epsilon_1\sqrt{\gamma_1})$ + 1, respectively. Let

$$L(\mathbf{x}) = l_1(x_d; r) + l_1(l_2(\sum_{i=1}^{d-1} l_1(x_i; R+r); R-r, R+r) - R; r).$$
(A.14)

Then it is time to show
$$T_{r,R}^d = \left\{ \mathbf{x} \in \mathbb{R}^d : x_d^2 + \left(\sqrt{\sum_{i=1}^{d-1} x_i^2} - R \right)^2 \le r^2 \right\} = \{ \mathbf{x} : L(\mathbf{x}) \le r^2 \}.$$

For $\mathbf{x} \in I_{T_{r,R}^d}(\mathbf{x})$, the following inequalities hold

$$x_i^2 \le (R+r)^2, 1 \le i \le d-1,$$
 (A.15)

$$R + r \ge \sqrt{\sum_{i=1}^{d-1} x_i^2} \ge R - r,$$
 (A.16)

 d_{-1}

862
863
$$x_d^2 \le r^2, (\sqrt{\sum_{i=1}^{a-1} x_i^2 - R})^2 \le r^2.$$
(A.17)

These indicate that $L(\mathbf{x}) = x_d^2 + \left(\sqrt{\sum_{i=1}^{d-1} x_i^2} - R\right)^2 \leq r^2$, when $\mathbf{x} \in T_{r,R}^d$. And when

 $\mathbf{x} \notin T^d_{r,R}$, if $L(\mathbf{x}) = x^2_d + \left(\sqrt{\sum_{i=1}^{d-1} x^2_i} - R\right)^2$ still holds, clearly $L(\mathbf{x}) > r^2$. Otherwise, one of the inequalities in A.15, A.16 and A.17 must break. If one of A.17 breaks, then clearly $L(\mathbf{x}) > r^2$. If A.16 does not hold, then $(\sqrt{x_1^2 + x_2^2} - R)^2 > r^2$, resulting $L(\mathbf{x}) > r^2$. The violation of A.15 resulting violation of A.16, which then leads to $L(\mathbf{x}) > r^2$.

To see how a ReLU network can estimate $L(\mathbf{x})$, we start by estimating each of its component. We define the following 2-layer networks. To make the overall network take $\mathbf{x} \in \mathbb{R}^d$ as input, we consider the structure in figure A.2.

Figure A.2: Network construction.

The size of parts in the network is provided in table A.1.

Table A.1: Sub-network Size.

Network	Target	Size
h_{1i}	$l_1(x_i; R+r)$	$s_{1i} = \left\lceil 4(R+r)^2/\epsilon_1 \right\rceil + 1$
h_2	$l_2(x; R-r, R+r)$	$s_2 = \left\lceil r/(\epsilon_1 \sqrt{R-r}) \right\rceil + 1$
h_{31}	$l_1(x;,r)$	$s_{31} = \left\lceil 4r_{\perp}^2/\epsilon_1 \right\rceil + 1$
h_{32}	$l_1(x_d;,r)$	$s_{32} = \left\lceil 4r^2/\epsilon_1 \right\rceil + 1$

By Lemma 4 and Lemma 3 and the given structure, a ReLU network \tilde{L} with depth 4 and size $(d-1)s_{11} + s_2 + s_{31} + s_{32} + 2$, where d = 3, can approximate $L(\mathbf{x})$ such that

$$\sup_{\mathbf{x}} |L(\mathbf{x}) - \tilde{L}(\mathbf{x})| \le d\epsilon_1.$$
(A.18)

The next step is to threshold $L(\mathbf{x})$. Consider a function

$$f(x) = \begin{cases} 1, & x < r^2 - \delta, \\ \frac{r^2 - x}{\delta}, & x \in [r^2 - \delta, r^2], \\ 0, & x > r^2. \end{cases}$$
(A.19)

This function approximates a thresholding function $I[x \leq r^2]$ but with error inside the interval $[r^2 - \delta, r^2]$. By Lemma 2, a 2-layer ReLU network \tilde{f} with size 2 can represent f(x). Then $\tilde{f} \circ \tilde{L}$ is a ReLU network with depth 5 and size $(d-1)s_{11} + s_2 + s_{31} + s_{32} + 4$, such that

$$\sup_{\mathbf{x}} |f \circ L(\mathbf{x}) - f \circ L(\mathbf{x})| \le \epsilon_1, \tag{A.20}$$

with letting $\epsilon_1 = \epsilon_1/d$.

Let $h(\mathbf{x}) = \tilde{f} \circ \tilde{L}(\mathbf{x})$. We claim that $h(\mathbf{x})$ is the desired network with depth 5 and size

$$(d-1)s_{11} + s_2 + s_{31} + s_{32} + 4$$

= $\frac{d}{\epsilon_1}(4(d-1)(R+r)^2 + 8r^2 + \frac{r}{\sqrt{R-r}}) + 9$
= $O(\frac{d^2}{\epsilon_1}).$ (A.21)

944

945

946

947

948

923

920 921 922

> To finalize our proof, we just need to bound the error $||h(\mathbf{x}) - I_{T_{r,R}^d}(\mathbf{x})||_{L_2(\mu)}$. The proof follows proof of Proposition 1. The error is divided into two parts and is bounded separately. The only difference is we define S_{δ} to be $S_{\delta} = \left\{ \mathbf{x} \in \mathbb{R}^d : r^2 - \delta \leq x_d^2 + \left(\sqrt{\sum_{i=1}^{d-1} x_i^2} - R \right)^2 \leq r^2 \right\}$, such that

$$\int_{S_{\delta}} \mu(\mathbf{x}) d\mathbf{x} \le \epsilon_2. \tag{A.22}$$

We can get $I_1 \leq \epsilon_2$, and $I_2 \leq \epsilon_1$. Let $\epsilon_1 = \epsilon_2 = \epsilon/2$, we have

$$||h(\mathbf{x}) - I(\mathbf{x})||_{L_2(\mu)} \le \epsilon.$$
(A.23)

And h has size at most $\frac{2d}{\epsilon}(4(d-1)(R+r)^2+8r^2+\frac{r}{\sqrt{R-r}})+9.$

A.4 Approximating Topological Representatives

After getting the size arising from fundamental manifolds, we proceed to study the combination of them. We start by proving the representative property.

Lemma 1 (Topological Representative). Let $\mathcal{M} \subset \mathbb{M}$ be a d-dimensional manifold from the thickened 1-manifold family. There exist a set of m_1 d-balls $\mathcal{B} = \{B_{r_i}^d(\mathbf{c}_i)\}_{i=1}^{m_1}$ and a set of m_2 solid d-tori $\mathcal{T} = \{T_{r_i,R_i}^d(\mathbf{c}_i)\}_{i=1}^{m_2}$, such that \mathcal{M} is homeomorphic to the union $(\bigcup_{B\in\mathcal{B}} B) \cup (\bigcup_{T\in\mathcal{T}} T)$, where $m_1 + m_2 \leq \beta(\mathcal{M})$ is a constant integer. We term $\mathcal{M}' =$ $(\bigcup_{B\in\mathcal{B}} B) \cup (\bigcup_{T\in\mathcal{T}} T)$ as the **topological representative** of \mathcal{M} .

949 950

951 *Proof.* Since $\mathcal{M} \subset \mathbb{M}$, regarding the definition, \mathcal{M} is homeomorphic to connect sum or 952 disjoint union of m thickened 1-manifolds. A thickened 1-manifold is denoted as $\mathcal{M}^1 \times B^{d-1}$. 953 And based on the classification theorem of 1-manifold, \mathcal{M}^1 is homeomorphic either to a circle S^1 or I = [0, 1]. If $\mathcal{M}^1 \sim S^1$, then $\mathcal{M}^1 \times B^{d-1} \sim S^1 \times B^{d-1} \sim T^d_{r,R}$. If $\mathcal{M}^1 \sim I$, 954 955 then $\mathcal{M}^1 \times B^{d-1} \sim I \times B^{d-1} \sim B_r^d$. Now let \mathcal{M}_1 and \mathcal{M}_2 be two thickened 1-manifold, the 956 connected sum of \mathcal{M}_1 and \mathcal{M}_2 , denoted by $\mathcal{M}_1 \oplus \mathcal{M}_2$, can be represented by the union of 957 two manifolds $\mathcal{M}_1 \cup \mathcal{M}_2$. Since \mathcal{M} is homeomorphic to connect sum or disjoint union of m thickened 1-manifolds, suppose m_1 of them are homeomorphic to B_r^d and m_2 of them are homeomorphic to $T_{r,R}^d$. Therefore, $\mathcal{M} \sim (\bigcup_{B \in \mathcal{B}} B) \cup (\bigcup_{T \in \mathcal{T}} T)$. 958 959

Notice that among \mathcal{B} , the union is disjoint union, otherwise the union is still homeomorphic to a B_r^d . Similarly, the union between \mathcal{B} and \mathcal{T} is also disjoint union, otherwise the union is still homeomorphic to a solid torus $T_{r,R}^d$. The union among \mathcal{T} could be joint union or disjoint union. For two solid tori T_1^d and T_2^d , $\beta(T_1^d) = \beta(T_1^d) = 2$. $\beta(T_1^d \cup T_2^d) \ge 3 > 2$. Overall, $\beta(\mathcal{M}) \ge m_1 + m_2$.

966

967 968 Lemma 7 (Manifold Union). \mathcal{M}_1 and \mathcal{M}_2 are two manifolds in \mathbb{R}^d . $I_{\mathcal{M}_1}$ can be approximated 969 by a ReLU network h_1 with depth $d_1 + 1$ and size at most s_1 with error $R(h_1) < \epsilon_1$, $I_{\mathcal{M}_2}$ 970 can be approximated by a ReLU network h_2 with depth $d_2 + 1$ and size at most s_2 with error 971 $R(h_2) < \epsilon_2$. Then $I_{\mathcal{M}_1 \cup \mathcal{M}_2}$ can be approximated within error $\epsilon_1 + \epsilon_2$ by a ReLU network with depth at most max $\{d_1, d_2\} + 2$ and size at most $s_1 + s_2 + 2$. *Proof.* We represent $I_{\mathcal{M}_1 \cup \mathcal{M}_2} = I_{x>0} \circ (I_{\mathcal{M}_1} + I_{\mathcal{M}_2})$ by a threshold function $I_{x>0}$. The threshold function can be approximate by a function

 $f(x) = \begin{cases} 0, & x \le 0\\ \frac{x}{\delta}, & x \in (0, \delta)\\ 1, & x \ge \delta. \end{cases}$ (A.24)

with errors only in $(0, \delta)$. f can be represented by a 2-layer ReLU network h_f with size 2. Then if let $h = h_f \circ (h_1 + h_2)$, according to Lemma 4 and 3, h is a neural network with depth max $\{d_1, d_2\} + 2$ and size $s_1 + s_2 + 2$. Then we bound the error

$$\begin{aligned} ||h - I_{\mathcal{M}_{1} \cup \mathcal{M}_{2}}||_{L_{2}(\mu)} &= ||h_{f} \circ (h_{1} + h_{2}) - I_{x>0} \circ (I_{\mathcal{M}_{1}} + I_{\mathcal{M}_{2}})||_{L_{2}(\mu)} \\ &\leq ||h_{f} \circ (h_{1} + h_{2}) - f \circ (I_{\mathcal{M}_{1}} + I_{\mathcal{M}_{2}})||_{L_{2}(\mu)} \\ &+ ||f \circ (I_{\mathcal{M}_{1}} + I_{\mathcal{M}_{2}}) - I_{x>0} \circ (I_{\mathcal{M}_{1}} + I_{\mathcal{M}_{2}})||_{L_{2}(\mu)} \\ &\leq ||h_{f} \circ (h_{1} + h_{2}) - h_{f} \circ (I_{\mathcal{M}_{1}} + I_{\mathcal{M}_{2}})||_{L_{2}(\mu)} \\ &\leq ||h_{f}||_{\infty} ||(h_{1} + h_{2}) - (I_{\mathcal{M}_{1}} + I_{\mathcal{M}_{2}})||_{L_{2}(\mu)} \\ &\leq ||(h_{1} + h_{2}) - (I_{\mathcal{M}_{1}} + I_{\mathcal{M}_{2}})||_{L_{2}(\mu)} \\ &\leq \epsilon_{1} + \epsilon_{2} \end{aligned}$$

Theorem 1 (Complexity Arising from Topology). Suppose \mathcal{M}' is the topological representative of d-manifold from the thickened 1-manifold family. Given $\epsilon > 0$, there exists a ReLU network $h : \mathbb{R}^d \to \mathbb{R}$ with depth at most $O(\log \beta)$ and size at most $O(\frac{d^2\beta^2}{\epsilon})$, that can approximate the indicator function $I_{\mathcal{M}'}$ with error $R(h) \leq \epsilon$ for any continuous distribution μ over \mathbb{R}^d . β is the topological complexity of \mathcal{M}' .

Proof. Since \mathcal{M}' is a topological representative, according to Lemma 1, there exist a set of m_1 d-balls $\mathcal{B} = \{B_{r_i}^d(\mathbf{c}_i)\}_{i=1}^{m_1}$ and a set of m_2 solid d-tori $\mathcal{T} = \{T_{r_i,R_i}^d(\mathbf{c}_i)\}_{i=1}^{m_2}$, such that $\mathcal{M}' = (\bigcup_{B \in \mathcal{B}} B) \cup (\bigcup_{T \in \mathcal{T}} T)$. Let $m = m_1 + m_2$. According to proposition 7, $I_{\mathcal{M}'}$ can be approximated by a ReLU network h with depth at most $\max\{d_1, d_2, ..., d_m\} + \log m$ and size at most $\sum_{i=1}^{m} s_i + \log m$, with error $R(h) \leq \sum_{i=1}^{m} \epsilon_i$. Then according to Proposition 1 and 2, $s_i \sim O(d^2/\epsilon_i)$, $d_i \sim O(1)$ and take ϵ_i to be all the same for all i = [m]. Let $\epsilon = m\epsilon_i$ and note that $m \leq \beta$. We have h has depth at most $O(\log \beta)$ and size at most $O(\frac{d^2\beta^2}{\epsilon})$, and can approximate $I_{\mathcal{M}'}$ with error $R(h) \leq \epsilon$.

A.5**OVERALL COMPLEXITY**

We present a result from Gonzalez-Diaz et al. (2019), which gives a bound of network size to represent a simplicial map.

Proposition 6 (Adapted from Theorem 4 in Gonzalez-Diaz et al. (2019)). Let us consider a simplicial map $\phi_c: |K| \to |L|$ between the underlying space of two finite pure simplicial complexes K and L. Then a two-hidden-layer feed-forward network \mathcal{N}_{ϕ} such that $\phi_c(x) =$ $\mathcal{N}_{\phi}(x)$ for all $x \in |K|$ can be explicitly defined. The size of N_f is D + d + k(D+1) + l(d+1), where D = dim(|K|) and d = dim(|L|), k and l are the number of simplices in K and L, respectively.

Theorem 2 (Main Theorem). Let $\mathcal{M} = \mathcal{M}_1 \sqcup \mathcal{M}_0 \subset \mathbb{R}^D$ be a d-dimensional manifold from the thickened 1-manifold family. \mathcal{M}_1 and \mathcal{M}_0 are two disjoint sub-manifolds of \mathcal{M} From the thickened 1-manifold family. \mathcal{M}_1 and \mathcal{M}_0 are two disjoint sub-manifolds of \mathcal{M}_1 representing two classes. The condition number of \mathcal{M} is $\frac{1}{\tau}$ and the total Betti number of \mathcal{M}_1 is β . Given a training set $\{(\mathbf{x}_i, y_i) | \mathbf{x}_i \in \mathcal{M}, y_i \in \{0, 1\}\}_{i=1}^n$, where \mathbf{x}_i are sampled i.i.d. from \mathcal{M} by a uniform distribution, and $y_i = I_{\mathcal{M}_1}(\mathbf{x}_i)$. For any $\delta > 0$, if inequality (8) holds, then for any $\epsilon > 0$, there exists a ReLU network g with depth at most $O(\log \beta + d \log \frac{1}{\tau} + \log \log \frac{1}{\tau\delta})$ and size at most $O(\frac{d^2\beta^2}{\epsilon} + \tau^{-d^2/2}\log^{d/2}\frac{1}{\tau\delta} + D\tau^{-d}\log\frac{1}{\tau\delta})$, such that)

$$P(R(g) \le \epsilon) > 1 - \delta, \tag{A.26}$$

where $R(g) = \int_{\mathcal{M}} (g - I_{\mathcal{M}_1})^2 \mu(\mathbf{x}) d\mathbf{x}$ with any continuous distribution μ .

1026 1027 Proof. Since $\mathcal{M} = \mathcal{M}_1 \sqcup \mathcal{M}_0$ is from thickened 1-manifold family, it has a topological 1028 representative $\mathcal{M}' = \mathcal{M}'_1 \sqcup \mathcal{M}'_0 \subset \mathbb{R}^d$, where \mathcal{M}'_1 and \mathcal{M}'_0 are topological representatives of \mathcal{M}_1 and \mathcal{M}_2 , respectively.

The proof follows by first constructing simplicial approximations |K| and |L| of \mathcal{M} and \mathcal{M}' , respectively. Then we represent a simplicial homeomorphism $\phi : |K| \to |L|$ by a neural network N_{ϕ} , where K is constructed from \mathcal{M} and L from \mathcal{M}' . Built on the top of this, a projection from \mathcal{M} to its simplicial approximation |K| is represented by another network N_p . The overall network can be constructed by $g = h \circ N_{\phi} \circ N_p$. Note that h is the function to approximate $I_{\mathcal{M}'_1}$, but the data after projection and homeomorphism is from $|L_1|$. There should be an error in this approximation. However, we will show that by using the true risk, having $|L_1| \subseteq \mathcal{M}'_1$ will make sure $||I_{|L_1|} - I_{\mathcal{M}'_1}||_{L_2(\mu')} = 0$. We move ahead by first constructing the network g, and then bounding the approximation error.

Network Construction. Given \mathcal{M} is a compact submanifold of \mathbb{R}^D and \mathbf{x}_i are sampled according to a uniform distribution, by Proposition 3, for all $0 < r < \tau/2$ and $n > \lambda_1(\log(\lambda_2) + \log(\frac{1}{\delta}))$ $(n \sim O(\tau^{-d}\log(1/\tau\delta))), U = \bigcup_i B_r^D(\mathbf{x}_i)$ has the same homology as \mathcal{M} with probability higher than $1 - \delta$. Note that every $B_r^D(\mathbf{x}_i)$ is contractible because $r \leq \tau$. 1039 1040 1041 1042 Therefore by the nerve theorem (Edelsbrunner & Harer, 2022), the nerve of U is homotopy 1043 equivalent to \mathcal{M} . Note that U is a collection of ϵ -balls. The nerve of U is the Cech complex, 1044 which is an abstract complex constructed as $\operatorname{Cech}(r) = \{ \sigma \subseteq X | \bigcap_{\mathbf{x} \in \sigma} B_r(\mathbf{x}) \neq 0 \}$. But since the dimension of \mathcal{M} is d, it suffices to only consider simplices with dimension $\leq d$. Delaunay 1045 complex is such a geometric construction that limits the dimension of simplices we get from 1046 a nerve. And in the other hand, we also do not want to lose the radius constraint. Here we 1047 construct the Alpha complex, a sub-complex of the Delaunay complex. It is constructed by 1048 intersecting each ball with the corresponding Voronoi cell, $R_{\mathbf{x}}(r) = B_r(\mathbf{x}) \cap V_{\mathbf{x}}$. The alpha 1049 complex is defined by

$$Alpha(r) = \{ \sigma \subseteq X | \bigcap_{\mathbf{x} \in \sigma} R_{\mathbf{x}}(r) \neq 0 \}.$$
(A.27)

1053 Based on the construction, Alpha(r) also has the same homotopy type as U. Bern et al. 1054 (1995) provided the number of simplices in a Delaunay complex of n vertices is bounded by 1055 $O(n^{\lceil d/2 \rceil})$. Since the Alpha complex is a sub-complex of Delaunay complex, the number of 1056 simplices in Alpha(r) is also bounded by

1057 1058

1068 1069

1051 1052

 $O(n^{\lceil d/2 \rceil}) = O(\tau^{-d^2/2} \log^{d/2} \frac{1}{\tau \delta})$ (A.28)

1059 Denote K = Alpha(r).

1061 We claim that there exists a a vertex map $\phi : \mathbf{x}_i \to \mathbf{x}'_i$ for i = 1, ..., n, such that with 1062 probability higher than $1 - \delta$, $U' = \bigcup_i B^{d'}_{r'}(\mathbf{x}'_i)$ has the same homology of \mathcal{M} . We prove this 1063 claim after the proof. We can construct an alpha complex from $\{\mathbf{x}'_i\}_{i=1}^n$ in a similar way, 1064 L = Alpha(r). The number of simiplices is also bounded by $O(\tau^{-d^2/2} \log^{d/2} \frac{1}{\tau\delta})$.

 ϕ can be extended to a simiplicial map $\phi: |K| \to |L|$ by

$$\phi(\mathbf{x}) = \sum_{i=1}^{n} b_i(\mathbf{x})\phi(\mathbf{x}_i).$$
(A.29)

1070 The map $b_i : |K| \to \mathbb{R}$ maps each point to its *i*-th barycentric coordinate. According to 1071 Proposition 6, there exists a ReLU network N_{ϕ} with depth 4 and size $O(\tau^{-d^2/2} \log^{d/2} \frac{1}{\tau\delta})$, 1072 such that $\phi(\mathbf{x}) = N_{\phi}(\mathbf{x})$ for all $\mathbf{x} \in |K|$.

1073 1074 Next we construct a network N_p that projects \mathcal{M} to its simplicial approximation |K|. The 1075 point is projecting $\mathbf{x} \in \mathcal{M}$ to its closest simplex $\sigma_{\mathbf{x}}$. According to the proof of theorem 1076 3 in Schonsheck et al. (2019), such projection can be represented as a neural network N_p 1076 with depth at most $\log n + 1$ and size at most O(nD). Lastly, by Theorem 1, a neural 1077 network h with depth at most $O(\log \beta)$ and size at most $O(\frac{d^2\beta^2}{\epsilon_1})$ can approximate $I_{\mathcal{M}'_1}$ with 1078 error $R(h) \leq \epsilon_1$. And by Lemma 3, $g = h \circ N_\phi \circ N_p$ has depth at most $O(\log(n\beta))$ and 1079 size $O(\frac{d^2\beta^2}{\epsilon_1} + \tau^{-d^2/2}\log^{d/2}\frac{1}{\tau\delta} + nD)$. Given $n \sim O(\tau^{-d}\log(1/\tau\delta))$, g has depth at most

Figure A.3: For a point $\mathbf{x}' \in |L_1|$ but $\mathbf{x}' \notin \mathcal{M}'_1$, we extend \mathcal{M}'_1 to make $\mathbf{x}' \in \mathcal{M}'_1$. The extended \mathcal{M}'_1 is still a topological representative.

1096 1097 $O(\log \beta + d \log \frac{1}{\tau} + \log \log \frac{1}{\tau\delta}) \text{ and size at most } O(\frac{d^2\beta^2}{\epsilon_1} + \tau^{-d^2/2} \log^{d/2} \frac{1}{\tau\delta} + D\tau^{-d} \log \frac{1}{\tau\delta}).$ 1098 Note that the probability of the existence for such network is larger than $(1 - \delta)^2 = 1 - 2\delta + \delta^2 > 1 - 2\delta$. We let $\delta = 2\delta$, such that with probability larger than $1 - \delta$, neural network g exists and g has depth at most $O(\log \beta + d \log \frac{1}{\tau} + \log \log \frac{1}{\tau\delta})$ and size at most $O(\frac{d^2\beta^2}{\epsilon_1} + \tau^{-d^2/2} \log^{d/2} \frac{1}{\tau\delta} + D\tau^{-d} \log \frac{1}{\tau\delta}).$

Bounding Approximation Error. Now it is time to bound the approximation error R(g). We split R(g) into two parts.

1105

1106 1107

1112 1113

1128

1131

1095

$$R(g) = ||g - I_{\mathcal{M}_1}||_{L_2(\mu)}$$

$$\leq ||h \circ N_{\phi} \circ N_p - I_{\mathcal{M}'_1} \circ \phi \circ N_p||_{L_2(\mu)} + ||I_{\mathcal{M}'_1} \circ \phi \circ N_p - I_{\mathcal{M}_1}||_{L_2(\mu)}$$
(A.30)

$$= I_1 + I_2.$$

1108 1109 1109 1100 1110 We first show that $I_2 = 0$. Note that $N_p : \mathcal{M} \to |K|$, and $\phi : |K| \to |L|$. We claim that for $\mathbf{x} \in \mathcal{M}_1, \phi \circ N_p(\mathbf{x}) \in L_1$ and if $\mathbf{x} \in \mathcal{M}_0, \phi \circ N_p(\mathbf{x}) \in L_0$. This is true because \mathcal{M}_1 and \mathcal{M}_2 are disjoint and L is homotopy equivalent to \mathcal{M} . Consequently, $I_{L_1} \circ \phi \circ N_p = I_{\mathcal{M}_1}$. Given

$$||I_{\mathcal{M}_{1}'} \circ \phi \circ N_{p} - I_{\mathcal{M}_{1}}||_{L_{2}(\mu)} = ||I_{\mathcal{M}_{1}'} \circ \phi \circ N_{p} - I_{L_{1}} \circ \phi \circ N_{p}||_{L_{2}(\mu)}$$

= $||I_{L_{1}} - I_{\mathcal{M}_{1}'}||_{L_{2}(\mu')}.$ (A.31)

1114 The second equation is derived by letting $\mu'(\mathbf{x}') = \mu \circ \phi \circ N_p(\mathbf{x})$. Now it suffices to show 1115 $||I_{L_1} - I_{\mathcal{M}'_1}||_{L_2(\mu')} = 0$. Note that μ' is a distribution supported on |L|, it can be naturally 1116 extended to \mathcal{M}' by set $\mu'(\mathbf{x}') = 0$ if $\mathbf{x}' \in \mathcal{M}'$ but $\mathbf{x}' \notin |L|$. For $\mathbf{x}' \in |L_1|$ but $\mathbf{x}' \notin \mathcal{M}'_1$, like 1117 shown in Figure A.3, we extend \mathcal{M}'_1 so that $\mathbf{x}' \in \mathcal{M}'_1$. And such extension always exists due 1118 to the construction of $|L_1|$. Note that $|L_1|$ is a alpha complex constructed from a r'-cover, in 1119 a way that there will be an edge if and only if two covering balls have intersection. Hence, for any edge $(\mathbf{x}'_i, \mathbf{x}'_j) \in |L_1|$, the length l_{ij} of it satisfies $l_{ij} < 2r' < \tau'$. And notice the radius of 1120 1121 the inner circle should be at least τ' . Otherwise, the reach will be less than τ' . Consequently, 1122 the edge of $|L_1|$ is always smaller than the radius of the inner circle. Therefore, one can always choose a \mathcal{M}'_1 , so that $\forall \mathbf{x}' \in |L_1|$ but $\mathbf{x}' \in \mathcal{M}'_1$. 1123

1124 After the expansion, $|L_1| \subseteq \mathcal{M}'_1$. As a conclusion, $||I_{L_1} - I_{\mathcal{M}'_1}||_{L_2(\mu')} = 0$. Hereby, we have proved $I_2 = 0$.

1127 Now we settle I_1 . Given N_{ϕ} is an exact representation of the simplicial map ϕ ,

$$I_1 = ||h - I_{\mathcal{M}_1'}||_{L_2(\mu')}. \tag{A.32}$$

1129 According to Theorem 1, $I_1 \leq \epsilon_1$. Combined together, we have

$$R(g) \le \epsilon_1. \tag{A.33}$$

1132 Note that this inequality holds only with probability larger than $1 - \delta$ because that is the 1133 probability we successfully recover the homology of \mathcal{M} by the training set and construct a simplicial homeomorphism. 1134 Claim 1. $\mathcal{M} \in \mathbb{R}^{D}$ is a d-dimensional manifold from thickened 1-manifold family. Suppose there exists a set $\{\mathbf{x}_{i} \in \mathcal{M}\}_{i=1}^{n}$ and radius r, such that $U = \bigcup_{i} B_{r}^{D}(\mathbf{x}_{i})$ is a cover of \mathcal{M} and has the same homology. Then there exists a $\mathcal{M}' \in \mathbb{R}^{d}$ that is a topological representative of \mathcal{M} . Denote the homeomorphism between them f. Then with probability larger than $1 - \delta$, $U' = \bigcup_{i} B_{r'}^{d}(f(\mathbf{x}_{i}))$ has the same homology as \mathcal{M} .

Proof. We let

$$c(r,\tau,\mathcal{M}) = \frac{vol(\mathcal{M})}{(cos^{d}\theta_{1})vol(B^{d}_{r/4})} \left(\log\frac{vol(\mathcal{M})}{(cos^{d}\theta_{2})vol(B^{d}_{r/8})} + \log\frac{1}{\delta}\right),$$
(A.34)

where $\theta_1 = \arcsin \frac{r}{8\tau}$, $\theta_2 = \arcsin \frac{r}{16\tau}$ and $0 < r < \tau/2$. Given a set $\{f(\mathbf{x}_i)\}_{i=1}^n$, apply proposition 3 to \mathcal{M}' . If

$$n > c(r', \tau', \mathcal{M}'), \tag{A.35}$$

1148 then with probability $1 - \delta$, $U' = \bigcup_i B_{r'}^d(f(\mathbf{x}_i))$ has the same homology as \mathcal{M}' , with $r' < \tau'/2$. 1149 Note that *n* already satisfy that $n > c(r, \tau, \mathcal{M})$, it suffices to show $c(r, \tau, \mathcal{M}) > c(r', \tau', \mathcal{M}')$.

1150 Since \mathcal{M}' is one of topological representatives of \mathcal{M} , we can always choose the radius of the 1151 fundamental members in \mathcal{M}' and choose the distance between \mathcal{M}'_1 and \mathcal{M}'_2 , to make sure 1152 that $\tau' > \tau$ and $vol(\mathcal{M}') < vol(\mathcal{M})$. Hence, we can choose r and r', such that $B^d_{r'} > B^d_r$. 1153 With the same δ , we have proved that $c(r, \tau, \mathcal{M}) > c(r', \tau', \mathcal{M}')$.
