Enhancing the Hierarchical Environment Design via Generative Trajectory Modeling

Anonymous Author(s) Affiliation Address email

Abstract

Unsupervised Environment Design (UED) is a paradigm that automatically gen-1 erates a curriculum of training environments, enabling agents trained in these 2 environments to develop general capabilities, i.e., achieving good zero-shot transfer 3 performance. However, existing UED approaches focus primarily on the random 4 generation of environments for open-ended agent training. This is impractical 5 in resource-limited scenarios where there is a constraint on the number of envi-6 ronments that can be generated. In this paper, we introduce a hierarchical MDP 7 framework for environment design under resource constraints. It consists of an 8 upper-level RL teacher agent that generates suitable training environments for a 9 lower-level student agent. The RL teacher can leverage previously discovered 10 environment structures and generate environments at the frontier of the student's 11 capabilities by observing the student policy's representation. Additionally, to alle-12 viate the time-consuming process of collecting the experience of the upper-level 13 teacher, we utilize recent advances in generative modeling to synthesize a trajec-14 tory dataset for training the teacher agent. Our method significantly reduces the 15 resource-intensive interactions between agents and environments, and empirical 16 experiments across various domains demonstrate the effectiveness of our approach. 17

18 1 Introduction

The advances of reinforcement learning (RL) [17] have promoted research into the problem of 19 training autonomous agents that are capable of accomplishing complex tasks. One interesting, yet 20 underexplored, area is training agents to perform well in unseen environments, a concept referred to 21 as zero-shot transfer performance. To this end, Unsupervised Environment Design (UED) [3] has 22 emerged as a promising paradigm to address this problem. The objective of UED is to automatically 23 generate environments in a curriculum-based manner, and training agents in these sequentially 24 25 generated environments can equip agents with general capabilities, enabling agents to learn robust and adaptive behaviors that can be transferred to new scenarios without explicit exposure during 26 training. 27

Existing approaches in UED primarily focus on building an adaptive curriculum for the environment 28 generation process to train the generally capable agent. Dennis et al. [3] formalize the problem of 29 finding adaptive curricula through a game involving an adversarial environment generator (teacher 30 31 agent), an antagonist agent (expert agent), and the protagonist agent (student agent). The RL-based teacher is designed to generate environments that maximize regret, defined as the difference between 32 the protagonist and antagonist agent's expected rewards. They show that these agents will reach 33 a Nash Equilibrium where the student agent learns the minimax regret policy. However, since the 34 teacher agent adapts solely based on the regret feedback, it is inherently difficult to adapt to student 35

policy changes. Meanwhile, training such an RL-based teacher remains a challenge because of the high computational cost of training an expert antagonist agent for each environment.

In contrast, domain randomization [19] based approaches circumvent the overhead of developing 38 an RL teacher by training agents in randomly generated environments, resulting in good empirical 39 performances. Building upon this, Jiang et al. [7] introduce an emergent curriculum by sampling 40 randomly generated environments with high regret value¹ to train the agent. Parker-Holder et al. 41 [10] then propose the adaptive curricula by manually designing a principled, regret-based curriculum, 42 which involves generating random environments with increasing complexity. While these domain 43 randomization-based algorithms have demonstrated good zero-shot transfer performance, they face 44 45 limitations in efficiently exploring large environment design spaces and exploiting the inherent structure of previously discovered environments. Moreover, existing UED approaches typically 46 rely on open-ended learning, necessitating a long training horizon, which is unrealistic in the real 47 world due to resource constraints. Our goal is to develop a teacher policy capable of generating 48 environments that are perfectly matched to the current skill levels of student agents, thereby allowing 49 students to achieve optimal general capability within a strict budget for the number of environments 50 generated and within a shorter training time horizon. 51

In this paper, we address these challenges by introducing a novel, adaptive environment design 52 framework. The core idea involves using a hierarchical Markov Decision Process (MDP) to simul-53 taneously formulate the evolution of an upper-level teacher agent, tasked with generating suitable 54 environments to train the lower-level student agent to achieve general capabilities. To accurately 55 guide the generation of environments at the frontier of the student agent's current capabilities, we 56 propose approximating the student agent's policy/capability by its performances across a set of diverse 57 evaluation environments, which acts as the state abstraction for the teacher's decision-making process. 58 The transitions in the teacher's state represent the trajectories of the student agent's capability after 59 training in the generated environment. However, collecting experience for the upper-level teacher 60 agent is slow and resource-intensive, since each upper-level MDP transition evolves a complete 61 training cycle of the student agent on the generated environment. To accelerate the collection of 62 upper-level MDP experiences, we utilize advances in diffusion models that can generate new data 63 points capturing complex distribution properties, such as skewness and multi-modality, exhibited 64 in the collected dataset [11]. Specifically, we employ diffusion probabilistic model [15, 6] to learn 65 the evolution trajectory of student policy/capability and generate synthetic experiences to enhance 66 the training efficiency of the teacher agent. Our method, called Synthetically-enhanced Hierarchical 67 Environment Design (SHED), automatically generates increasingly complex environments suited to 68 the current capabilities of student agents. 69

⁷⁰ In summary, we make the following contributions:

We develop a novel hierarchical MDP framework for UED that introduces a straightforward method
 to represent the current capability level of the student agent.

We introduce *SHED*, which utilizes diffusion-based techniques to generate synthetic experiences.
 This method can accelerate the training of the off-policy teacher agent.

We demonstrate that our method outperforms existing UED approaches (i.e., achieving a better general capability under resource constraints) in different task domains.

77 2 Preliminaries

⁷⁸ In this section, we provide an overview of two main research areas upon which our work is based.

79 2.1 Unsupervised Environment Design

The objective of UED is to generate a sequence of environments that effectively train the student agent to achieve a general capability. Dennis et al. [3] first model UED with an Underspecified Partially Observable Markov Decision Process (UPOMDP), which is a tuple

$$\mathcal{M} = < A, O, \Theta, S^{\mathcal{M}}, \mathcal{P}^{\mathcal{M}}, \mathcal{I}^{\mathcal{M}}, \mathcal{R}^{\mathcal{M}}, \gamma >$$

¹They approximate the regret value by the Generalized Advantage Estimate [12].

The UPOMDP has a set Θ representing the free parameters of the environments, which are 80 determined by the teacher agent and can be distinct to generate the next new environment. Further, 81 these parameters are incorporated into the environment-dependent transition function $\mathcal{P}^{\mathcal{M}}: S \times A \times \Theta \rightarrow S$. Here A represents the set of actions, S is the set of states. Similarly, $\mathcal{I}^{\mathcal{M}}: S \rightarrow O$ is the environment-dependent observation function, $\mathcal{R}^{\mathcal{M}}$ is the reward function, and γ is the discount factor. 82 83 84 Specifically, given the environment parameters $\vec{\theta} \in \Theta$, we denote the corresponding environment 85 instance as $\mathcal{M}_{\vec{a}}$. The student policy π is trained to maximize the cumulative rewards $V^{\mathcal{M}_{\vec{a}}}(\pi) =$ 86 $\sum_{t=0}^{T} \gamma^t r_t$ in the given environment $\mathcal{M}_{\vec{\theta}}$ under a time horizon T, and r_t are the collected rewards in $\mathcal{M}_{\vec{\theta}}$. Existing works on UED consist of two main strands: the RL-based environment generation 87 88

approach and the domain randomization-based environment generation approach. 89

The RL-based generation approach was first formalized by Dennis et al. [3] as a self-supervised RL 90

paradigm for generating environments. This approach involves co-evolving an environment generator 91

policy (teacher) with an agent policy π (student), where the teacher's role is to generate environment 92 instances that best support the student agent's continual learning. The teacher is trained to produce 93

challenging yet solvable environments that maximize the regret measure, which is defined as the 94

performance difference between the current student agent and a well-trained expert agent π^* within the current environment: $Regret^{\mathcal{M}_{\vec{\theta}}}(\pi,\pi^*) = V^{\mathcal{M}_{\vec{\theta}}}(\pi^*) - V^{\mathcal{M}_{\vec{\theta}}}(\pi)$. 95

96

The domain randomization-based generation approach, on the other hand, involves randomly generat-97 ing environments. Jiang et al. [7] propose to collect encountered environments with high learning 98 potentials, which are approximated by the Generalized Advantage Estimation (GAE) [12], and then 99 100 the student agent can selectively train in these environments, resulting in an emergent curriculum of increasing difficulty. Additionally, Parker-Holder et al. [10] adopt a different strategy by using 101 predetermined starting points for the environment generation process and gradually increasing com-102 plexity. They manually divide the environment design space into different difficulty levels and employ 103 human-defined edits to generate similar environments with high learning potentials. Their algorithm, 104 ACCEL, is currently the state-of-the-art (SOTA) in the field, and we use an edited version of ACCEL 105 as a baseline in our experiments. 106

2.2 Diffusion Probabilistic Models 107

Diffusion models [15] are a specific type of generative model that learns the data distribution. 108 Recent advances in diffusion-based models, including Langevin dynamics and score-based generative 109 models, have shown promising results in various applications, such as time series forecasting [18], 110 robust learning [9], anomaly detection [21] as well as synthesizing high-quality images from text 111 descriptions [8, 11]. These models can be trained using standard optimization techniques, such as 112 stochastic gradient descent, making them highly scalable and easy to implement. 113

In a diffusion probabilistic model, we assume a d-dimensional random variable $x_0 \in \mathbb{R}^d$ with an 114 unknown distribution $q(x_0)$. Diffusion Probabilistic model involves two Markov chains: a predefined 115 forward chain $q(x_k|x_{k-1})$ that perturbs data to noise, and a trainable reverse chain $p_{\phi}(x_{k-1}|x_k)$ that 116 converts noise back to data. The forward chain is typically designed to transform any data distribution 117 into a simple prior distribution (e.g., standard Gaussian) by considering perturb data with Gaussian noise of zero mean and a fixed variance schedule $\{\beta_k\}_{k=1}^K$ for K steps: 118 119

$$q(x_k|x_{k-1}) = \mathcal{N}(x_k; \sqrt{1 - \beta_k} x_{k-1}, \beta_t \mathbf{I}) \quad \text{and} \quad q(x_{1:K}|x_0) = \prod_{k=1}^K q(x_k|x_{k-1}), \tag{1}$$

where $k \in \{1, \ldots, K\}$, and $0 < \beta_{1:K} < 1$ denote the noise scale scheduling. As $K \to \infty$, x_K 120 will converge to isometric Gaussian noise: $x_K \to \mathcal{N}(0, \mathbf{I})$. According to the rule of the sum of 121 normally distributed random variables, the choice of Gaussian noise provides a closed-form solution 122 to generate arbitrary time-step x_k through: 123

$$x_k = \sqrt{\bar{\alpha}_k} x_0 + \sqrt{1 - \bar{\alpha}_k} \epsilon$$
, where $\epsilon \sim \mathcal{N}(0, \mathbf{I})$. (2)

Here $\alpha_k = 1 - \beta_k$ and $\bar{\alpha}_k = \prod_{s=1}^k \alpha_s$. The reverse chain $p_{\phi}(x_{k-1}|x_k)$ reverses the forward process by learning transition kernels parameterized by deep neural networks. Specifically, considering the 124 125 Markov chain parameterized by ϕ , denoising arbitrary Gaussian noise into clean data samples can be 126 written as: 127

$$p_{\phi}(x_{k-1}|x_k) = \mathcal{N}(x_{k-1}; \mu_{\phi}(x_k, k), \Sigma_{\phi}(x_k, k))$$

$$(3)$$

It uses the Gaussian form $p_{\phi}(x_{k-1}|x_k)$ because the reverse process has the identical function form as 128 the forward process when β_t is small [15]. Ho et al. [6] consider the following parameterization of 129

130 $p_{\phi}(x_{k-1}|x_k)$:

$$\mu_{\phi}(x_k,k) = \frac{1}{\alpha_k} \left(x_k - \frac{\beta_k}{\sqrt{1 - \alpha_k}} \epsilon_{\phi}(x_k,k) \right) \text{ and } \Sigma_{\phi}(x_k,k) = \tilde{\beta}_k^{1/2} \text{ where } \tilde{\beta}_k = \begin{cases} \frac{1 - \alpha_{k-1}}{1 - \alpha_k} \beta_k & k > 1\\ \beta_1 & k = 1 \end{cases}$$

 ϵ_{ϕ} is a trainable function to predict the noise vector ϵ from x_k . Ho et al. [6] show that training the reverse chain to maximize the log-likelihood $\int q(x_0) \log p_{\phi}(x_0) dx_0$ is equivalent to minimizing re-weighted evidence lower bound (ELBO) that fits the noise. They derive the final simplified optimization objective:

$$\mathcal{L}(\phi) = \mathbb{E}_{x_0,k,\epsilon} \left[\|\epsilon - \epsilon_{\phi}(\sqrt{\bar{\alpha}_k}x_0 + \sqrt{1 - \bar{\alpha}_k}\epsilon, k)\|^2 \right].$$
(5)

Once the model is trained, new data points can be subsequently generated by first sampling a random vector from the prior distribution, followed by ancestral sampling through the reverse Markov chain in Equation 3.

138 **3** Approach

In this section, we formally describe our method, Synthetically-enhanced Hierarchical Environment
 Design (SHED), which is a novel framework for UED under resource constraints. The SHED
 incorporates two key components that differentiate it from existing UED approaches:

• A hierarchical MDP framework to generate suitable environments,

• A generative model to generate the synthetic trajectories.

SHED uses a hierarchical MDP framework where an RL teacher leverages the observed student's 144 policy representation to generate environments at the student's capabilities frontier. Such targeted 145 environment generation process enhances the student's general capability by utilizing the underlying 146 structure of previously discovered environments, rather than relying on the open-ended random 147 generation. Besides, SHED leverages advances in generative models to generate synthetic trajectories 148 that can be used to train the off-policy teacher agent, which significantly reduces the costly interactions 149 between the agents and the environments. The overall framework is shown in Figure 1, and the 150 pseudo-code is provided in Algorithm 1. 151

152 3.1 Hierarchical Environment Design

The objective is to generate a limited number of environments that are designed to enhance the general 153 capability of the student agent. Inspired by the principles of PAIRED [3], we adopt an RL-based 154 approach for the environment generation process. To better generate suitable environments tailored 155 to the current student skill level, SHED uses the hierarchical MDP framework, consisting of an 156 upper-level RL teacher policy Λ and a lower-level student policy π . Specifically, the teacher policy, 157 $\Lambda:\Pi\to\Theta$, maps from the space of all potential student policies Π to the space of environment 158 parameters Θ . Existing RL-based methods (e.g., PARIED) rely solely on regret feedback and 159 fail to effectively capture the nuances of the student policy. To address this challenge, SHED 160 enhances understanding by encoding the student policy π into a vector that serves as the state 161 abstraction for teacher Λ . Rather than compressing the knowledge in the student policy network, we 162 approximate the embedding of the student policy π by assessing performance across a set of diverse 163 evaluation environments. This performance vector, denoted as $p(\pi)$, gives us a practical estimate 164 of the student's current general capabilities, enabling the teacher to customize the next training 165 environments accordingly. In our hierarchical framework, the environment generation process is 166 governed by discrete-time dynamics. We delve into the specifics below. 167

Upper-level teacher MDP. The upper-level teacher operates at a coarser layer of student policy abstraction and generates environments to train the lower-level student agent. This process can be formally modeled as an MDP by the tuple $\langle S^u, A^u, P^u, R^u, \gamma^u \rangle$:

• S^u represents the upper-level state space. Typically, $s^u = p(\pi) = [p_1, \dots, p_m]$ denotes the student performance vector across m diverse evaluation environments. This vector serves as the representation of the student policy π and is charged by the teacher

representation of the student policy π and is observed by the teacher.

Algorithm 1 SHED

Input: real data ratio $\psi \in [0, 1]$, evaluate environment set θ^{eval} , reward function R;

- 1: **Initialize:** diffusion model D, teacher policy Λ , real and synthetic replay buffer $\mathcal{B}_{real}, \mathcal{B}_{syn} = \emptyset$;
- 2: for episode $ep = 1, \ldots, K$ do
- Initialize student policy π 3:
- Evaluate π on θ^{eval} and get state $s^u = p(\pi)$ 4:
- 5: for Budget $t = 1, \ldots, T$ do
- generate $\vec{\theta} \sim \Lambda$, and create $\mathcal{M}_{\vec{\theta}}(\pi)$ 6:
- train π on $\mathcal{M}_{\vec{\theta}}$ to maximize $V^{\breve{\vec{\theta}}}(\pi)$ 7:
- evaluate π on θ^{eval} and get next state s'8:
- compute teacher's reward r_t according to R9:
- add experience $(s_t^u, \vec{\theta}, r_t^u, s_t^{u,\prime})$ to \mathcal{B}_{real} train D with samples from \mathcal{B}_{real} 10:
- 11:
- generate synthetic experiences from D and 12: add them to \mathcal{B}_{syn}
- train Λ on samples from $\mathcal{B}_{real} \bigcup \mathcal{B}_{syn}$ mixed 13: with ratio ψ
- 14: set s = s';
- 15: end for 16: end for
- **Output:** Λ , π , D

Figure 2: The illustration of the environment generation process.

• A^u is the upper-level action space. The teacher observes the abstraction of the student policy, 174 s^u and produces an upper-level action a^u which is the environment parameters $\vec{\theta}$. $\vec{\theta}$ (a^u) is then 175 used to generate specific environment instances $\mathcal{M}_{\vec{\theta}}$. Thus the upper-level action space A^u is the 176 environment parameter space Θ . 177

 P^{u} denotes the action-dependent transition dynamics of the upper-level state. The general capability 178 of the student policy evolves due to training the student agent on the generated environments. 179

• R^u provides the upper-level reward to the teacher at the end of training the student on the generated 180 environment. The design of R^u will be discussed in Section 3.3. 181

As shown in Figure 2, given the student policy π , the teacher Λ first observes the representation 182 of the student policy, $s^u = [p_1, \ldots, p_m]$. Then teacher produces an upper-level action a^u which 183 corresponds to the environment parameters. These environment parameters are subsequently used 184 to generate specific environment instances. The lower-level student policy π will be trained on the 185 generated environments for C training steps. The upper-level teacher collects and stores the student 186 policy evolution transition $(s^u, a^u, r^u, s^{u,\prime})$ every C times steps for off-policy training. The teacher 187 agent is trained to maximize the cumulative reward giving the budget for the number of generated 188 environments. The choice of the evaluation environments will be discussed in Section 3.3. 189

Lower-level student MDP. The generated environment is fully specified for the student, characterized by a Partially Observable Markov Decision Process (POMDP), which is defined by a tuple $M_{\vec{\theta}} = <$ 190 191 $A, O, S^{\vec{\theta}}, \mathcal{P}^{\vec{\theta}}, \mathcal{I}^{\vec{\theta}}, \mathcal{R}^{\vec{\theta}}, \gamma >$, where A represents the set of actions, O is the set of observations, $S^{\vec{\theta}}$ is the set of states determined by the environment parameters $\vec{\theta}$, similarly, $\mathcal{P}^{\vec{\theta}}$ is the environment-192 193 dependent transition function, and $\mathcal{I}^{\vec{\theta}}: \vec{\theta} \to O$ is the environment-dependent observation function, 194 $\mathcal{R}^{\vec{\theta}}$ is the reward function, and γ is the discount factor. At each time step t, the environment produces a 195 state observation $s_t \in S^{\vec{\theta}}$, the student agent samples the action $a_t \sim A$ and interacts with environment 196 $\vec{\theta}$. The environment yields a reward r_t according to the reward function $\mathcal{R}^{\vec{\theta}}$. The student agent is 197 trained to maximize their cumulative reward $V^{\vec{\theta}}(\pi) = \sum_{t=0}^{C} \gamma^t r_t$ for the current environment under a finite time horizon C. The student agent will learn a good general capability from training on a 198 199 sequence of generated environments. 200

The hierarchical framework enables the teacher agent to systematically measure and enhance the general capability of the student agent and to adapt the training process accordingly. However, it's worth noting that collecting student policy evolution trajectories $(s^u, a^u, r^u, s^{u, \prime})$ to train the teacher agent is notably slow and resource-intensive, since each transition in the upper-level teacher MDP encompasses a training horizon of *C* timesteps for the student in the generated environment. Thus, it is essential to reduce the need for costly collection of upper-level teacher experiences.

207 3.2 Generative Trajectory Modeling

In this section, we will formally introduce a generative model designed to ease the collection of upper-208 level MDP experience. This will allow us to train our teacher policy more efficiently. In particular, we 209 first utilize a diffusion model to learn the conditional data distribution from the collected experiences 210 $\tau = \{(s_t^u, a_t^u, r_t^u, s_t^{p,\prime})\}$. Later we can use the reverse chain in the diffusion model to generate the 211 synthetic trajectories that can be used to help train the teacher agent, thereby alleviating the need 212 for extensive and time-consuming collection of upper-level teacher experiences. We deal with two 213 different types of timesteps in this section: one for the diffusion process and the other for the upper-214 level teacher agent, respectively. We use subscripts $k \in 1, \ldots, K$ to represent diffusion timesteps 215 and subscripts $t \in 1, \ldots, T$ to represent trajectory timesteps in the teacher's experience. 216

In the image domain, the diffusion process is implemented across all pixel values of the image. In our setting, we diffuse over the next state $s^{u,i}$ conditioned the given state s^u and action a^u . We construct our generative model according to the conditional diffusion process:

$$q(s_k^{u,\prime}|s_{k-1}^{u,\prime}), \quad p_\phi(s_{k-1}^{u,\prime}|s_k^{u,\prime},s^u,a^u)$$

As usual, $q(s_k^{u,\prime}|s_{k-1}^{u,\prime})$ is the predefined forward noising process while $p_{\phi}(s_{k-1}^{u,\prime}|s_k^{u,\prime}, s^u, a^u)$ is the trainable reverse denoising process. We begin by randomly sampling the collected experiences $\tau = \{(s_t^u, a_t^u, r_t^u, s_t^{u,\prime})\}$ from the real experience buffer \mathcal{B}_{real} . Giving the observed state s^u and action a^u , we use the reverse process p_{ϕ} to represent the generation of the next state $s^{u,\prime}$:

$$p_{\phi}(s_{0:K}^{u,\prime}|s^{u}, a^{u}) = \mathcal{N}(s_{K}^{u,\prime}; 0, \mathbf{I}) \prod_{k=1}^{K} p_{\phi}(s_{k-1}^{u,\prime}|s_{k}^{u,\prime}, s^{u}, a^{u})$$

At the end of the reverse chain, the sample $s_0^{u,\prime}$, is the generated next state $s^{u,\prime}$. Similar to Ho et al. [6], we parameterize $p_{\phi}(s'_{k-1}|s'_k, s^u, a^u)$ as a noise prediction model with the covariance matrix fixed as $\Sigma_{\phi}(s^{u,\prime}_k, s^u, a^u, k) = \beta_i \mathbf{I}$, and the mean is

$$\mu_{\phi}(s_i^{u,\prime}, s^u, a^u, k) = \frac{1}{\sqrt{\alpha_k}} \left(s_k^{u,\prime} - \frac{\beta_k}{\sqrt{1 - \bar{\alpha}_k}} \epsilon_{\phi}(s_k^{u,\prime}, s^u, a^u, k) \right)$$

 $\epsilon_{\phi}(s_{k}^{u,\prime}, s^{u}, a^{u}, k)$ is the trainable denoising function, which aims to estimate the noise ϵ in the noisy input $s_{k}^{u,\prime}$ at step k.

Training objective. We employ a similar simplified objective to train the conditional ϵ - model:

$$\mathcal{L}(\phi) = \mathbb{E}_{(s^u, a^u, s^{u,\prime}) \sim \tau, k \sim \mathcal{U}, \epsilon \sim \mathcal{N}(0, \mathbf{I})} \left[\|\epsilon - \epsilon_{\phi}(s_k^{u,\prime}, s^u, a^u, k)\|^2 \right]$$
(6)

Where $s_k^{u,\prime} = \sqrt{\bar{\alpha}_k} s^{u,\prime} + \sqrt{1 - \bar{\alpha}_k} \epsilon$. The intuition for the loss function $\mathcal{L}(\phi)$ is to predict the noise 227 $\epsilon \sim \mathcal{N}(\hat{0}, \mathbf{I})$ at the denoising step k, and the diffusion model is essentially learning the student 228 policy involution trajectories collected in the real experience buffer \mathcal{B}_{reals} . Note that the reverse 229 process necessitates a substantial number of steps K [15]. Recent research by Xiao et al. [22] has 230 demonstrated that enabling denoising with large steps can reduce the total number of denoising steps 231 232 K. To expedite the relatively slow reverse sampling process (as it requires computing ϵ_{ϕ} networks K times), we use a small value of K. Similar to Wang et al. [20], while simultaneously setting 233 $\beta_{\min} = 0.1$ and $\beta_{\max} = 10.0$, we define: 234

$$\beta_k = 1 - \exp\left(\beta_{\min} \times \frac{1}{K} - 0.5(\beta_{\max} - \beta_{\min})\frac{2k - 1}{K^2}\right)$$

This noise schedule is derived from the variance-preserving Stochastic Differential Equation by Song et al. [16].

Generate synthetic trajectories. Once the diffusion model has been trained, it can be used to generate 237 synthetic experience data by starting with a draw from the prior $s_K^{u,r} \sim \mathcal{N}(0, \mathbf{I})$ and successively generating denoised next state, conditioned on the given s^u and a^u through the reverse chain p_{ϕ} . 238 239 Note that the giving condition action a can either be randomly sampled from the action space or use 240 another diffusion model to learn the action distribution giving the initial state s^u . This new diffusion 241 model is essentially a behavior-cloning model that aims to learn the teacher policy $\Lambda(a^u|s^u)$. This 242 process is similar to the work of Wang et al. [20]. We discuss this process in detail in the appendix. 243 In this paper, we randomly sample a^u as it is straightforward and can also increase the diversity in 244 the generated synthetic experience to help train a more robust teacher agent. 245

After obtaining the generated next state $s^{u,'}$ conditioned on s^u, a^u , we compute reward r^u using teacher's reward function $R(s^u, a^u, s^{u,'})$. The specifics of how the reward function is chosen are explained in the following section.

249 3.3 Rewards and Choice of evaluate environments

Selection of evaluation environments. The upper-level teacher generates environments tailored 250 for the lower-level student to improve its general capability. Thus it is important to select a set of 251 diverse suitable evaluation environments as the performance vector reflects the student agent's general 252 capabilities and serves as an approximation of the policy's embedding. Fontaine and Nikolaidis 253 [5] propose the use of quality diversity (QD) optimization to collect high-quality environments that 254 exhibit diversity for the agent behaviors. Similarly, Bhatt et al. [1] introduce a QD-based algorithm for 255 256 dynamically designing such evaluation environments based on the current agent's behavior. However, it's worth noting that this QD-based approach can be tedious and time-consuming, and the collected 257 evaluation environments heavily rely on the given agent policy. 258

Given these considerations, it is natural to take advantage of the domain randomization algorithm, as it has demonstrated compelling results in generating diverse environments and training generally capable agents. In our approach, we first discretize the environment parameters into different ranges, then randomly sample from these ranges, and combine these parameters to generate evaluation environments. This method can generate environments that may induce a diverse performance for the same policy, and it shows promising empirical results in the final experiments.

Reward design. We define the reward function for the upper-level teacher policy as a parameterized function based on the improvement in student performance in the evaluation environments after training in the generated environment:

$$R(s^{u}, a^{u}, s^{u, \prime}) = \sum_{i=1}^{m} (p'_{i} - p_{i})$$

This reward function gives positive rewards to the upper-level teacher for taking action to create 268 the right environment to improve the overall performance of students across diverse environments. 269 However, it may encourage the teacher to obtain higher rewards by sacrificing student performance 270 in one subset of evaluation environments to improve student performance in another subset, which 271 conflicts with our objective to develop a student agent with general capabilities. Therefore, we need 272 to consider fairness in the reward function to ensure that the generated environment can improve 273 student's general capabilities. Similar to [4], we build our fairness metric on top of the change 274 in student's performance in each evaluation environment, denoted as $\omega_i = p'_i - p_i$, and we have 275 $\bar{\omega} = \frac{1}{m} \sum_{i=1}^{m} \omega_i$. We then measure the fairness of the teacher's action using the coefficient of 276 variation of student performances: 277

$$cv(s^{u}, a^{u}, s^{u,\prime}) = \sqrt{\frac{1}{m-1} \sum_{i} \frac{(\omega_{i} - \bar{\omega})^{2}}{\bar{\omega}^{2}}}$$
 (7)

A teacher is considered to be fair if and only if the cv is smaller. As a result, our reward function is:

$$R(s^{u}, a^{u}, s^{u,\prime}) = \sum_{i=1}^{m} (p'_{i} - p_{i}) - \eta \cdot cv(s^{u}, a^{u}, s^{u,\prime})$$
(8)

Here η is the coefficient that balances the weight of fairness in the reward function (We set a small value to η). This reward function motivates the teacher to generate training environments that can improve student's general capability.

Figure 3: *Left*: The average zero-shot transfer performances on the test environments in the Lunar lander environment (mean and standard error). *Right*: The average zero-shot transfer performances on the test environments in the BipedalWalker (mean and standard error).

282 4 Experiments

In this section, we conduct experiments to compare SHED to other leading approaches on three 283 domains: Lunar Lander, maze and a modified BipedalWalker environment. Experimental details and 284 285 hyperparameters can be found in the Appendix. Specifically, our primary comparisons involve SHED and *h-MDP* (our proposed hierarchical approach without diffusion model aiding in training) against 286 four baselines: domain randomization [19], ACCEL, [10], Edited ACCEL(with slight modifications 287 that it does not revisit the previously generated environments), PAIRED [3]. In all cases, we 288 train a student agent via Proximal Policy Optimization (PPO [13], and train the teacher agent via 289 Deterministic policy gradient algorithms (DDPG [14]), because DDPG is an off-policy algorithm and 290 can learn from both real experiences and the synthetic experiences. 291

Setup. For each domain, we construct a set of evaluation environments and a set of test environments. The vector of student performances in the evaluation environments is used as the approximation of the student policy (as the observation to teacher agent), and the performances in the test environments are used to represent the student's zero-shot transfer performances (general capabilities). Note that in order to obtain a fair comparison of zero-shot transfer performance, the evaluation environments and test environments do not share the same environment and they are not present during training.

Lunar Lander. This is a classic rocket trajectory optimization problem. In this domain, student agents are tasked with controlling a lander's engine to safely land the vehicle. Before the start of each episode, teacher algorithms determine the environment parameters that are used to generate environments in a given play-through, which includes gravity, wind power, and turbulence power. These parameters directly alter the difficulty of landing the vehicle safely. The state is an 8-dimensional vector, which includes the coordinates of the lander, its linear velocities, its angle, its angular velocity, and two booleans that represent whether each leg is in contact with the ground or not.

We train the student agent for 1e6 environment time steps and periodically test the agent in test 305 environments. The parameters for the test environments are randomly generated and fixed during 306 training. We report the experiment results on the left side of Figure 3. As we can see, student 307 agents trained under SHED consistently outperform other baselines and have minimal variance in 308 309 transfer performance. During training, the baselines, except h-MDP, show a performance dip in the middle. This phenomenon could potentially be attributed to the inherent challenge of designing the 310 appropriate environment instance in the large environment parameter space. This further demonstrates 311 the effectiveness of our hierarchical design (SHED and h-MDP), which can successfully create 312 environments that are appropriate to the current skill level of the students. 313

Bipedalwalker. We also evaluate *SHED* in the modified BipedalWalker from Parker-Holder et al. [10]. In this domain, the student agent is required to control a bipedal vehicle and navigate across the terrain, and the student receives a 24-dimensional proprioceptive state with respect to its lidar sensors, angles, and contacts. The teacher is tasked to select eight variables (including ground roughness, the

number of stairs steps, min/max range of pit gap width, min/max range of stump height, and min/max 318 range of stair height) to generate the corresponding terrain. 319

We use similar experiment settings in prior UED works, we train all the algorithms for 1e7 environ-320 ment time steps, and then evaluate their generalization ability on ten distinct test environments in 321 Bipedal-Walker domain. The parameters for the test environments are randomly generated and fixed 322 during training. As shown in Figure 3, our proposed method SHED surpasses all other baselines and 323 achieves performance levels nearly on par with the SOTA (ACCEL). Meanwhile, SHED maintains a 324 slight edge in terms of stability and overall performance and PAIRED suffers from a considerable 325 degree of variance in its performance. 326

Partially observable Maze. Here we study navigation tasks, where an agent must explore to find a 327 goal while navigating around obstacles. The environment is partially observable, and the agent's field 328 of view is limited to a 3×3 grid area. Unlike the previously mentioned domains, maze environments 329 are non-parametric and cannot be directly represented by compact parameter vectors due to their 330 high complexity. To solve this challenge, we propose a novel method to generate maze by leveraging 331 advances in large language models (e.g., ChatGPT). Specifically, we implement a retrieval-augmented 332 generation (RAG) process to optimize the ChatGPT's output such that it can generate desired maze 333 environments. This process ensures that large language models reference authoritative knowledge 334 335 bases to generate feasible mazes. To simplify the teacher's action space, we extracted several key 336 factors that constitute the teacher's action space (environmental parameters) for maze generation. 337 Details on maze generation are provided in Appendix D.3, and prompt are included in Appendix D.4.

The average zero-shot transfer perfor-338 mances are reported in Figure 4. No-339 tably, SHED demonstrates the highest 340 performance, consistently improving 341 and achieving the highest cumulative 342 rewards. The performance of h-MDP 343 steadily improves but does not reach 344 the highest levels, which further high-345 lights the advantages of incorporat-346 ing the generated synthetic datasets 347 to train an effective RL teacher agent. 348 Meanwhile, Accel-Edit and Accel 349 show higher variances in performance, 350 indicating that random teachers are 351 352 less stable in finding a suitable environment to train student agents. 353

Ablation and additional Experi-

Figure 4: Average zero-shot transfer performance on the test environments in the maze environments.

ments In Appendix C, we evaluate the ability of the diffusion model to generate the synthetic student policy involution trajectories. We 356 further provide ablation studies to assess the impact of different design choices in Appendix E.1. 357 Additionally, in Appendix E.2, we conduct experiments to show how the algorithm performs under 358 359 different settings, including scenarios with a larger budget constraint on the number of generated environments or a larger weight assigned to CV fairness rewards. Notably, all results consistently 360 demonstrate the effectiveness of our approach. 361

Conclusion 5 362

354

355

In this paper, we introduce an adaptive approach for efficiently training a generally capable agent 363 under resource constraints. Our approach is general, utilizing an upper-level MDP teacher agent 364 that can guide the training of the lower-level MDP student agent agent. The hierarchical framework 365 can incorporate techniques from existing UED works, such as prioritized level replay (revisiting 366 environments with high learning potential). Furthermore, we have described a method to assist the 367 experience collection for the teacher when it is trained in an off-policy manner. Our experiment 368 demonstrates that our method outperforms existing UED methods, highlighting its effectiveness as a 369 curriculum-based learning approach within the UED framework. 370

434 A Theorem

Theorem 1 There exists a finite evaluation environment set that can capture the student's general capabilities and the performance vector $[p_1, ..., p_m]$ is a good representation of the student policy.

⁴³⁷ To prove this, we first provide the following Assumption:

Assumption 1 Let $p(\pi, \vec{\theta})$ denote the performance of student policy π in an environment $\vec{\theta}$. For $\forall i$ -th dimension of the environment parameters, denoted as θ_i , when changing the θ_i to θ'_i to get a new environment $\vec{\theta'}$ while keeping other environment parameters fixed, there $\exists \delta_i > 0$, if $|\theta'_i - \theta_i| \le \delta_i$, we have $|p(\pi, \vec{\theta'}) - p(\pi, \vec{\theta})| \le \epsilon_i$, where $\epsilon_i \to 0$.

If this is true, we then can construct a finite set of environments, and the student performances in those environments can represent the performances in all potential environments generated within the certain environment parameters open interval combinations, and the set of those open intervals combinations cover the environment parameter space Θ .

We begin from the simplest case where we only consider using one environment parameter to generate 446 environments, denoted as θ_i . We can construct a finite environment parameter set for environment parameters, which is $\{\theta_i^{min} + 1/2 * \delta_i, \theta_i^{min} + 3/2 * \delta_i, \theta_i^{min} + 7/2 * \delta_i, \dots, \theta_i^{max} - \delta_i/2\}$. Assume 447 448 the set size is L_i . We let the set $\{\vec{\theta}_i\}_{i=1}^{L_i}$ denote the corresponding generated environments. This is 449 served as the representative environment set. Then the student performances in those environments 450 are denoted as $\{p(\pi, \vec{\theta_i})\}_{i=1}^{L_i}$, which we call it as **representative performance vector set**. We can 451 divide the space for θ_i into a finite set of open intervals with size L_i , which is $\{[\theta_i^{min}, \theta_i^{min} + 3/2 * \delta_i), (\theta_i^{min} + 1/2 * \delta_i, \theta_i^{min} + 5/2 * \delta_i), (\theta_i^{min} + 5/2 * \delta_i, \theta_i^{min} + 9/2 * \delta_i), \dots, (\theta_i^{max} - 3/2 * \delta_i, \theta_i^{max}]\},$ which we call it as **representative parameter interval set**, also denoted as $\{(\theta_i - \delta_i, \theta_i + \delta)\}_{i=1}^{L_i}$. 452 453 454 For any environment generated in those intervals, denoted as $\vec{\theta}'_i$, the performance $p(\pi, \vec{\theta}'_i)$ can always 455 be represented by the $p(\pi, \vec{\theta_i})$ which is in the same interval, as $|p(\pi, \vec{\theta_i'}) - p(\pi, \vec{\theta_i})| \le \epsilon_i$, where 456 $\epsilon_i \to 0$. In such cases, the finite set of environmental parameter interval, $\frac{d}{d} |p(n, v_i)| = \epsilon_i$, where $\epsilon_i \to 0$. In such cases, the finite set of environmental parameter intervals $\{\theta_i^{min} + 1/2 * \delta_i, \theta_i^{min} + 3/2 * \delta_i, \theta_i^{min} + 7/2 * \delta_i, \dots, \theta_i^{max} - \delta_i/2\}$ fully covers the entire parameter space Θ . We can find a representative environment set $\{\theta_i\}_{i=1}^{L_i}$ that is capable of approximating the performance of the student policy within the open environment set $\{\theta_i\}_{i=1}^{L_i}$. 457 458 459 student policy within the open parameter intervals combination. This set effectively characterizes the 460 general performance capabilities of the student policy π . 461

Then we extend to two environment parameter design space cases. Let's assume that the environment 462 is generated by two-dimension environment parameters. Then, for each environment parameter, 463 $\theta_i \in \{\theta_1, \theta_2\}$. We can find the same open interval set for each parameter. Specifically, for each θ_i , 464 there exists a δ_i , such that if $|\theta'_i - \theta_i| \leq \delta_i$, we have $|p(\pi, \vec{\theta'}) - p(\pi, \vec{\theta})| \leq \epsilon_i$, where $\epsilon_i \to 0$. Hence, we let $\delta = \min\{\delta_1, \delta_2\}$ and $\epsilon = \epsilon_1 + \epsilon_2$. Thus the new **representative environment set** is the set 465 466 that includes the any combination of $\{[\theta_1, \theta_2]\}$ where $\theta_1 \in \{\vec{\theta_i}\}_{i=1}^{L_1}$ and $\theta_2 \in \{\vec{\theta_j}\}_{j=1}^{L_2}$. We can get 467 the representative performance vector set as $\{p(\pi, [\vec{\theta}_i, \vec{\theta}_j])\}_{i \in [1, L_1], j \in [1, L_2]}$. We then can construct the representative parameter interval set as $\{[(\theta_i - \delta, \theta_i + \delta), (\theta_j - \delta, \theta_j + \delta)]\}_{i \in [1, L_1], j \in [1, L_j]}$. 468 469 As a result, for any new environments $[\vec{\theta}'_i, \vec{\theta}'_i]$, we can find the representative environment whose 470 environment parameters are in the same parameter interval $[\vec{\theta_i}, \vec{\theta_i}]$, such that their performance 471 difference is smaller than $\epsilon = \epsilon_1 + \epsilon_2$ for all $\forall i \in [1, L_1], \forall j \in [1, L_2]$: 472

$$|p(\pi, [\vec{\theta_i}, \vec{\theta_j}]) - p(\pi, [\vec{\theta_i}, \vec{\theta_j}])| = |p(\pi, [\vec{\theta_i'}, \vec{\theta_j}]) - p(\pi, [\vec{\theta_i'}, \vec{\theta_j}]) + p(\pi, [\vec{\theta_i'}, \vec{\theta_j}]) - p(\pi, [\vec{\theta_i}, \vec{\theta_j}])|$$

$$\leq |p(\pi, [\vec{\theta_i'}, \vec{\theta_j'}]) - p(\pi, [\vec{\theta_i'}, \vec{\theta_j}])| + |p(\pi, [\vec{\theta_i'}, \vec{\theta_j}]) - p(\pi, [\vec{\theta_i}, \vec{\theta_j}])|$$

$$\leq \delta_j + \delta_i$$

$$= \delta$$
(9)

In such cases, the finite set of environmental parameter intervals $\{[(\theta_i - \delta, \theta_i + \delta), (\theta_j - \delta, \theta_j + \delta)]\}_{i \in [1, L_1], j \in [1, L_j]}$ fully covers the entire parameter space Θ . We can find a representative environment set $\{\theta_i\}_{i=1}^{L_i}$ that is capable of approximating the performance of the student policy within the

Table 1: The teacher policies corresponding to the three approaches for UED. $U(\Theta)$ is a uniform distribution over environment parameter space, \tilde{D}_{π} is a baseline distribution, $\bar{\theta}_{\pi}$ is the trajectory which maximizes regret of π , and v_{π} is the value above the baseline distribution that π achieves on that trajectory, c_{π} is the negative of the worst-case regret of π . Details are described in PAIRED [3].

UED Approaches	Teacher Policy	Decision Rule
DR [19]	$\Lambda(\pi) = U(\Theta)$	Randomly sample
PARIED [3]	$\Lambda(\pi) = \{ \bar{\theta}_{\pi} : \frac{c_{\pi}}{v_{\pi}}, \tilde{D}_{\pi} : \text{otherwise} \}$	Minimax Regret
SHED (ours)	$\Lambda(\pi) = \arg\max Q_{\pi}(s = \pi, a = \vec{\theta})$	Maximize reward
	$\vec{\theta} \in \Theta$	

open parameter intervals combination. This set effectively characterizes the general performance capabilities of the student policy π .

Similarly, we can show this still holds when the environment is constructed by a larger dimension 478 environment parameters, where we set $\delta = \min{\{\delta_i\}}$, and $\epsilon = \sum_i \epsilon_i$, and we have $\delta > 0$, $\epsilon \to 0$. The overall logic is that we can find a finite set, which is called **representative environment set**, and 479 480 we can use performances in this set to represent any performances in the environments generated 481 in the **representative parameter interval set**, which is called **representative performance vector** 482 set. Finally, we can show that representative parameter interval set fully covers the environment 483 parameter space. Thus there exists a finite evaluation environment set that can capture the student's 484 general capabilities and the performance vector, called representative performance vector set, 485 $[p_1, \ldots, p_m]$ is a good representation of the student policy. 486

487 **B** Details about the Generative model

488 B.1 Generative model to generate synthetic next state

Here, we describe how to leverage the diffusion model to learn the conditional data distribution in the 489 collected experiences $\tau = \{(s_t^u, a_t^u, r_t^u, s_t^{u, \prime})\}$. Later we can use the trainable reverse chain in the 490 diffusion model to generate the synthetic trajectories that can be used to help train the teacher agent, 491 resulting in reducing the resource-intensive and time-consuming collection of upper-level teacher 492 experiences. We deal with two different types of timesteps in this section: one for the diffusion 493 process and the other for the upper-level teacher agent, respectively. We use subscripts $k \in 1, \ldots, K$ 494 to represent diffusion timesteps and subscripts $t \in 1, \ldots, T$ to represent trajectory timesteps in the 495 teacher's experience. 496

In the image domain, the diffusion process is implemented across all pixel values of the image. In our setting, we diffuse over the next state $s^{u,i}$ conditioned the given state s^u and action a^u . We construct our generative model according to the conditional diffusion process:

$$q(s_k^{u,\prime}|s_{k-1}^{u,\prime}), \quad p_\phi(s_{k-1}^{u,\prime}|s_k^{u,\prime},s^u,a^u)$$

As usual, $q(s_k^{u,\prime}|s_{k-1}^{u,\prime})$ is the predefined forward noising process while $p_{\phi}(s_{k-1}^{u,\prime}|s_k^{u,\prime}, s^u, a^u)$ is the trainable reverse denoising process. We begin by randomly sampling the collected experiences $\tau = \{(s_t^u, a_t^u, r_t^u, s_t^{u,\prime})\}$ from the real experience buffer \mathcal{B}_{real} .

We drop the superscript u here for ease of explanation. Giving the observed state s and action a, we use the reverse process p_{ϕ} to represent the generation of the next state s':

$$p_{\phi}(s'_{0:K}|s,a) = \mathcal{N}(s'_{K};0,\mathbf{I}) \prod_{k=1}^{K} p_{\phi}(s'_{k-1}|s'_{k},s,a)$$
(10)

At the end of the reverse chain, the sample s'_0 , is the generated next state s'. As shown in Section 2.2, $p_{\phi}(s'_{k-1}|, s'_k, s, a)$ could be modeled as a Gaussian distribution $\mathcal{N}(s'_{k-1}; \mu_{\theta}(s'_k, s, a, k), \Sigma_{\theta}(s'_k, s, a, k))$. Similar to Ho et al. [6], we parameterize $p_{\phi}(s'_{k-1}|s'_k, s, a)$ as a noise prediction model with the covariance matrix fixed as

$$\Sigma_{\theta}(s'_k, s, a, k) = \beta_i \mathbf{I}$$

and mean is

$$\mu_{\theta}(s'_{i}, s, a, k) = \frac{1}{\sqrt{\alpha_{k}}} \left(s'_{k} - \frac{\beta_{k}}{\sqrt{1 - \bar{\alpha}_{k}}} \epsilon_{\theta}(s'_{k}, s, a, k) \right)$$

Where $\epsilon_{\theta}(s'_{k}, s, a, k)$ is the trainable denoising function, which aims to estimate the noise ϵ in the noisy input s'_{k} at step k. Specifically, giving the sampled experience (s, a, s'), we begin by sampling $s'_{K} \sim \mathcal{N}(0, \mathbf{I})$ and then proceed with the reverse diffusion chain $p_{\phi}(s'_{k-1}|, s'_{k}, s, a)$ for $k = K, \ldots, 1$. The detailed expression for s'_{k-1} is as follows:

$$\frac{s'_k}{\sqrt{\alpha_k}} - \frac{\beta_k}{\sqrt{\alpha_k(1-\bar{\alpha}_k)}} \epsilon_\theta(s'_k, s, a, k) + \sqrt{\beta_k} \epsilon, \tag{11}$$

where $\epsilon \sim \mathcal{N}(0, \mathbf{I})$. Note that $\epsilon = 0$ when k = 1.

Training objective. We employ a similar simplified objective, as proposed by Ho et al. [6] to train the conditional ϵ - model through the following process:

$$\mathcal{L}(\theta) = \mathbb{E}_{(s,a,s')\sim\tau,k\sim\mathcal{U},\epsilon\sim\mathcal{N}(0,\mathbf{I})} \left[\|\epsilon - \epsilon_{\phi}(s'_k,s,a,k)\|^2 \right]$$
(12)

Where $s'_k = \sqrt{\bar{\alpha}_k}s' + \sqrt{1 - \bar{\alpha}_k}\epsilon$. \mathcal{U} represents a uniform distribution over the discrete set $\{1, \ldots, K\}$. The intuition for the loss function $\mathcal{L}(\theta)$ tries to predict the noise $\epsilon \sim \mathcal{N}(0, \mathbf{I})$ at the denoising step k, 512 513 and the diffusion model is essentially learning the student policy involution trajectories collected in 514 the real experience buffer \mathcal{B}_{reals} . Note that the reverse process necessitates a substantial number of 515 steps K, as the Gaussian assumption holds true primarily under the condition of the infinitesimally 516 517 limit of small denoising steps [15]. Recent research by Xiao et al. [22] has demonstrated that enabling denoising with large steps can reduce the total number of denoising steps K. To expedite the relatively 518 slow reverse sampling process outlined in Equation 3.2 (as it requires computing ϵ_{ϕ} networks K 519 times), we use a small value of K, while simultaneously setting $\beta_{\min} = 0.1$ and $\beta_{\max} = 10.0$. 520 Similar to Wang et al. [20], we define: 521

$$\begin{aligned} \beta_k &= 1 - \alpha_k \\ &= 1 - \exp\left(\beta_{\min} \times \frac{1}{K} - 0.5(\beta_{\max} - \beta_{\min})\frac{2k - 1}{K^2}\right) \end{aligned}$$

This noise schedule is derived from the variance-preserving Stochastic Differential Equation by Song et al. [16].

Generate synthetic trajectories. Once the diffusion model has been trained, it can be used 524 to generate synthetic experience data by starting with a draw from the prior $s'_K \sim \mathcal{N}(0, \mathbf{I})$ and 525 successively generating denoised next state, conditioned on the given s and a through the reverse 526 527 chain p_{ϕ} in Equation 3.2. Note that the giving condition action a can either be randomly sampled 528 from the action space (which is also the environment parameter space) or use another diffusion model to learn the action distribution giving the initial state s. In such case, this new diffusion model is 529 essentially a behavior-cloning model that aims to learn the teacher policy $\Lambda(a|s)$. This process is 530 similar to the work of Wang et al. [20]. We discuss this process in detail in the appendix. In this paper, 531 we randomly sample a as it is straightforward and can also increase the diversity in the generated 532 synthetic experience to help train a more robust teacher agent. 533

534 B.2 Generative model to generate synthetic action

Once the diffusion model has been trained, it can be used to generate synthetic experience data by starting with a draw from the prior $s'_K \sim \mathcal{N}(0, \mathbf{I})$ and successively generating denoised next state, conditioned on the given s and a through the reverse chain p_{ϕ} in Equation 3.2. Note that the giving condition action a can either be randomly sampled from the action space (which is also the environment parameter space) or we can train another diffusion model to learn the action distribution giving the initial state s, and then use the trained new diffusion model to sample the action a giving the state s. This process is similar to the work of Wang et al. [20].

542 In particular, We construct another conditional diffusion model as:

$$q(a_k|a_{k-1}), \quad p_{\phi}(a_{k-1}|a_k, s)$$

Figure 5: The distribution of the real s' and the synthetic s' conditioned on (s, a).

As usual, $q(a_k|a_{k-1})$ is the predefined forward noising process while $p_{\phi}(a_{k-1}|a_k, s)$ is the trainable reverse denoising process. we represent the action generation process via the reverse chain of the conditional diffusion model as

$$p_{\phi}(a_{0:K}|s) = \mathcal{N}(a_K; 0, \mathbf{I}) \prod_{k=1}^{K} p_{\phi}(a_{k-1}|a_k, s)$$
(13)

At the end of the reverse chain, the sample a_0 , is the generated action a for the giving state s. Similarly, we parameterize $p_{\phi}(a_{k-1}|a_k, s)$ as a noise prediction model with the covariance matrix fixed as

$$\Sigma_{\theta}(a_k, s, k) = \beta_i \mathbf{I}$$

and mean is

$$\mu_{\theta}(a_i, s, k) = \frac{1}{\sqrt{\alpha_k}} \left(a_k - \frac{\beta_k}{\sqrt{1 - \bar{\alpha}_k}} \epsilon_{\theta}(a_k, s, k) \right)$$

546 Similarly, the simplified loss function is

$$\mathcal{L}^{a}(\theta) = \mathbb{E}_{(s,a)\sim\tau,k\sim\mathcal{U},\epsilon\sim\mathcal{N}(0,\mathbf{I})} \left[\|\epsilon - \epsilon_{\phi}(a_{k},s,k)\|^{2} \right]$$
(14)

⁵⁴⁷ Where $a_k = \sqrt{\overline{\alpha}_k}a + \sqrt{1 - \overline{\alpha}_k}\epsilon$. \mathcal{U} represents a uniform distribution over the discrete set $\{1, \dots, K\}$. ⁵⁴⁸ The intuition for the loss function $\mathcal{L}^a(\theta)$ tries to predict the noise $\epsilon \sim \mathcal{N}(0, \mathbf{I})$ at the denoising step k, ⁵⁴⁹ and the diffusion model is essentially a behavior cloning model to learn the student policy collected ⁵⁵⁰ in the real experience buffer \mathcal{B}_{reals} .

Once this new diffusion model is trained, the generation of the synthetic experience can be formulated as:

- we first randomly sample the state from the collected real trajectories $s \sim \tau$;
- we use the new diffusion model discussed above to mimic the teacher's policy to generate the actions *a*;
- giving the state s and action a, we use the first diffusion model presented in the main paper to generate the next state s';
- we compute the reward r according to the reward function, and add the final generated synthetic experience (s, a, r, s') to the synthetic experience buffer \mathcal{B}_{syn} to help train the teacher agent.

Figure 6: The distribution of the real $[s'_1, s'_2, s'_3]$ (red) and the synthetic $[s'_1, s'_2, s'_3]$ (blue) giving the fixed (s^u, a^u) . Specifically, the noise ε in $f(s^u, a^u)$ is (i).*left* figure: $\varepsilon = \epsilon$, (ii).*middle* figure: $\varepsilon = 3 * \epsilon$, (iii).*right* figure: $\varepsilon = 10 * \epsilon$, where $\epsilon \sim \mathcal{N}(0, 1)$.

⁵⁶¹ C Empirical analysis of generative model

562 C.1 Ability to generate good synthetic trajectories

We begin by investigating *SHED*'s ability to assist in collecting experiences for the upper-level MDP teacher. This involves the necessity for *SHED* to prove its ability to accurately generate synthetic experiences for teacher agents. To check the quality of these generated synthetic experiences, we employ a diffusion model to simulate some data for validation (even though Diffusion models have demonstrated remarkable success across vision and NLP tasks).

We design the following experiment: given the teacher's observed state $s^u = [p_1, p_2, p_3, p_4, p_5]$, 568 where p_i denotes the student performance on *i*-th evaluation environment. and given the teacher's 569 action $a^u = [a_1, a_2, a_3]$, which is the environment parameters and are used to generate corresponding 570 environment instances. We use a neural network $f(s^u, a^u)$ to mimic the involution trajectories of 571 the student policy π . That is, with the input of the state s^u and action a^u into the neural network, it 572 outputs the next observed state $s^{u,\prime} = [p'_1, p'_2, p'_3, p'_4, p'_5]$, indicating the updated student performance 573 vector on the evaluation environments after training in the environment generated by a^u . In particular, 574 we add a noise ε into $s^{u,t}$ to represent the uncertainty in the transition. We first train our diffusion 575 model on the real dataset $(s^u, a^u, s^{u'})$ generated by neural network $f(s^u, a^u)$. We then set a fixed (s^u, a^u) pair and input them into $f(s^u, a^u)$ to generate 200 samples of real $s^{u'}$. The trained diffusion 576 577 model is then used to generate 200 synthetic $s^{u,\prime}$ conditioned on the fixed (s^u, a^u) pair. 578

The results are presented in Figure 6, we can see that the generative model can effectively capture the distribution of real experience even if there is a large uncertainty in the transition, indicated by the value of ε . This provides evidence that the diffusion model can generate useful experiences conditioned on (s^u, a^u) . It is important to note that the marginal distribution derived from the reverse diffusion chain provides an implicit, expressive distribution, such distribution has the capability to capture complex distribution properties, including skewness and multi-modality.

585 C.2 addition experiments on diffusion model

We further provide more results to show the ability of our generative model to generate synthetic 586 trajectories where the noise is extremely small. In such cases, the actual next state s' will converge to 587 a certain value, and the synthetic next state $s^{syn,t}$ generated by the diffusion model should also be 588 very close to that value, then the diffusion model has the ability to sample the next state $s_0^{syn,'}$ which 589 can accurately represent the next state. We present the results in Figure 5. Specifically, this figure 590 shows when the noise is very small in the actual next state, which is $0.05 * \epsilon$, and $\epsilon \sim \mathcal{N}(0, 1)$. Giving 591 any condition (s, a) pair, we selectively report on (s_i, a_i) , where x-axis is the a_i value, and y-axis 592 is the s_i value. The student policy with initial performance vector s is trained on the environments 593 generated by the teacher's action a. We report the new performance s'_i of student policy on *i*-th 594 environments after training in the z-axis. In particular, if two points s'_i and $s^{syn,i}_i$ are close, it indicates 595 that the diffusion model can successfully generate the actual next state. As we can see, when the 596 noise is extremely small, our diffusion model can accurately predict the next state of s'_i giving any 597 condition (s, a) pair. 598

Figure 7: *Left*: The ablation study in the Lunar lander environment which investigates the effect of the size of the evaluation environment set. We provide the average zero-shot transfer performances on the test environments (mean and standard error). *Right*: Zero-shot transfer performance on the test environments under a longer time horizon in Lunar lander environments(mean and standard error).

599 D Additional Experiment Details

600 D.1 Hyperparameters

We set the learning rate 1e-3 for actor, and 3e-3 for critic, we set gamma $\gamma = 0.999$, $\lambda = 0.95$, and set coefficient for the entropy bonus (to encourage exploration) as 0.01. For each environment, we conduct 50 PPO updates for the student agent, and We can train on up to 50 environments, including replay. For our diffusion model, the diffusion discount is 0.99, and batch size is 64, τ is 0.005, learning rate is 3e - 4. The synthetic buffer size is 1000, and the ratio is 0.25.

606 D.2 Experiments Compute Resources

⁶⁰⁷ All the models were trained on a single NVIDIA GeForce RTX 3090 GPU and 16 CPUs.

608 D.3 Maze document

Here we provide the document shows the instruction to generate feasible maze environments.

There are several factors that can affect the difficulty of a maze. Here are 610 some key factors to consider: 611 1. Maze Size: Larger mazes generally increase the complexity and difficulty 612 as the agent has more states to explore. Typically, the maze size should be 613 larger than 4x4 and smaller than 15*15. 614 - If the size is 7*7 or smaller, the maze size is considered easy. 615 616 If the size is larger than 7*7 but smaller than 10*10, the maze size is 617 considered medium. - If the maze size is larger than 10x10 but smaller than 15*15, the maze 618 size is considered hard. 619 2. Maze Structure: The complexity of the paths, including the number of twists, 620 turns, and dead-ends, can significantly impact navigation strategies. The 621 presence of narrow corridors versus wide-open spaces also plays a role. 622 - If there are fewer than 2 turns in the feasible path from the start position 623 624 to the end position, the maze structure is considered easy. - If there are more than 2 turns but fewer than 4 turns in the path from the 625 start position to the end position, the maze structure is considered medium. 626 - If there are 4 or more turns in the path from the start position to the end 627 628 position, the maze structure is considered hard. 3. Goal Location: The distance from the starting position to the end position 629 630 also affects difficulty. - If the path from the start position to the end position requires fewer than 631

```
5 steps, the goal location is considered easy.
632
   - If the path from the start position to the end position requires 5 to 10
633
   steps, the goal location is considered medium.
634
   - If the path from the start position to the end position requires more than
635
   10 steps, the goal location is considered hard.
636
   4. Start Location: The starting position can also affect the difficulty of
637
   the maze. The starting position is categorized into five levels:
638
   - If the start position is close to 1, it means it should be located as close
639
   to the top left of the maze.
640
   - If the start position is close to 2, it means it should be located as close
641
   to the top right of the maze.
642
   - If the start position is close to 3, it means it should be located as close
643
   to the bottom left of the maze.
644
   - If the start position is close to 4, it means it should be located as close
645
   to the bottom right of the maze.
646
   - If the start position is close to 5, it means it should be located as close
647
   to the center of the maze.
648
   Please note that the generated maze uses -1 to represent blocks, 0 to
649
   represent the feasible path, 1 to represent the start position, and 2 to represent
650
   the end position. Must ensure that there is a feasible path in the generated maze!
651
   A feasible path means that 1 and 2 are connected directly through 0s, or 1 and 2
652
   are connected directly. For example:
653
    Feasible Maze:
654
   Maze = [
655
      [0, -1, -1, 2],
656
      [1, -1, 0, 0],
657
      [0, -1, 0, -1],
658
659
      [0, 0, 0, -1],
    ]
660
    Non-Feasible Mazes:
661
    Maze = [
662
      [0, -1, -1, 2],
663
      [1, -1, 0, 0],
664
      [0, -1, -1, 0],
665
666
      [0, 0, 0, -1],
   ]
667
   Or
668
    Maze = [
669
670
      [1, -1],
      [-1, 2]
671
   ٦
672
   These second example does not have any feasible path.
673
674
675
```

676 D.4 Prompt for RAG

⁶⁷⁷ We provide our prompt for the Retrieval Augmented Generation as follows:

```
Please refer to the document, and generate a maze with feasible path. The
difficulty level for the maze size is {maze_size_level}, and the difficulty
level for the maze structure is {maze_structure_level}, he difficulty level
for the goal location is {goal_location_level}, he difficulty level for
the start location is {start_position_level}.
```

683 E Additional experiments

684 E.1 Additional experiments about ablation studies

We also provide ablation analysis to evaluate the impact of different design choices in Lunar lander domain, including (a) a larger evaluation environment set; (b) a bigger budget for constraint on the number of generated environments (which incurs a longer training time horizon). The results are reported in Figure 7.

We explore the impact of introducing the diffusion model in collecting synthetic teacher's experience 689 and varying the size of the evaluation environment set. Specifically, as we can see from the right side 690 of Figure 7, the SHED consistently outperforms h-MDP, indicating the effectiveness of introducing 691 the generative model to help train the upper-level teacher policy. Furthermore, we find that when 692 increasing the size of the evaluation environment set, we can have a better result in the student 693 transfer performances. The intuition is that a larger evaluation environment set, encompassing a more 694 diverse range of environments, provides a better approximation of the student policy according to the 695 Theorem 1. However, the reason why SHED with 30 evaluation environments slightly outperforms 696 SHED with 40 evaluation environments is perhaps attributed to the increase in the dimension of the 697 student performance vector, which amplifies the challenge of training an effective diffusion model 698 with a limited dataset. 699

We conduct experiments in Lunar lander under a longer time horizon. The results are provided on the right side of Figure 7. As we can see, our proposed algorithm *SHED* can efficiently train the student agent to achieve the general capability in a shorter time horizon, This observation indicates that our proposed environment generation process can better generate the suitable environments for the current student policy, thereby enhancing its general capability, especially when there is a constraint on the number of generated environments.

706 E.2 Additional experiments on Lunar lander

we also conduct experiments to show how the algorithm performs under different settings, such as a larger weight of cv fairness rewards ($\eta = 10$). The results are provided in Figure 8. We noticed an interesting finding: when fairness reward has a high weightage, our algorithm tends to generate environments at the onset that lead to a rapid decline and subsequent improvement in student performance across all test environments. This is done to avoid acquiring a substantial negative fairness reward and thereby maximize the teacher's cumulative reward. Notably, the student's final performance still surpasses other baselines at the end of training.

Figure 8: Zero-shot transfer performance on the test environments with a larger cv value coefficient in Lunar lander environments.

713

714 We further show in detail how the performance of different methods changes in each testing environ-

⁷¹⁵ ment during training (see Figure 9 and Figure 10).

Figure 9: Detail how the performance of different methods changes in each testing environment during training (mean and error)

716 E.3 Additional experiments on Maze

We selectively report some results of zero-shot transfer performances in maze environments. The
 results are provided in Figure

719 F Discussion

720 F.1 Limitations

The limitation of this work comes from the UED framework, as UED is limited to the use of parameterized environments. This results in our experimental domain being relatively simple.

Figure 10: Detail how the performance of different methods changes in each testing environment during training (mean and error)

Figure 11: Zeros-shot transfer performance on test environments in maze environemnts

However, our work proposes a new hierarchical structure, and our policy representation is not only of
 great help for UED, but also has certain inspirations for hierarchical RL. Additionally, in the world
 model of UED (Genie [2]), the environment generator (teacher) focuses on creating video games, a
 domain that is compatible with our proposed application of upsampling the teacher agent's experience

⁷²⁷ using a diffusion model (since the state is image-based).

728 NeurIPS Paper Checklist

729	1.	Claims
730		Question: Do the main claims made in the abstract and introduction accurately reflect the
731		paper's contributions and scope?
732		Answer: [Yes]
733		Justification: Yes, the main claims made in the abstract and introduction accurately reflect
734		the paper's contributions and scope.
735		Guidelines:
736		• The answer NA means that the abstract and introduction do not include the claims
737		made in the paper.
738		• The abstract and/or introduction should clearly state the claims made, including the
739		contributions made in the paper and important assumptions and limitations. A No or
740		NA answer to this question will not be perceived well by the reviewers.
741		• The claims made should match theoretical and experimental results, and reflect how
742		much the results can be expected to generalize to other settings.
743		• It is fine to include aspirational goals as motivation as long as it is clear that these goals
744		are not attained by the paper.
745	2.	Limitations
746		Question: Does the paper discuss the limitations of the work performed by the authors?
747		Answer: [Yes]
748		Justification: The limitations of this work is discussed in Appendix F.1.
749		Guidelines:
750		• The answer NA means that the paper has no limitation while the answer No means that
751		the paper has limitations, but those are not discussed in the paper.
752		• The authors are encouraged to create a separate "Limitations" section in their paper.
753		• The paper should point out any strong assumptions and how robust the results are to
754		violations of these assumptions (e.g., independence assumptions, noiseless settings,
755		model well-specification, asymptotic approximations only holding locally). The authors
756		should reflect on how these assumptions might be violated in practice and what the
757		implications would be.
758		• The authors should reflect on the scope of the claims made, e.g., if the approach was
759		only tested on a few datasets or with a few runs. In general, empirical results often
760		The day has the first of the forter that is the for
761		• The authors should reflect on the factors that influence the performance of the approach.
762		is low or images are taken in low lighting. Or a speech to text system might not be
763		used reliably to provide closed captions for online lectures because it fails to handle
765		technical jargon.
766		• The authors should discuss the computational efficiency of the proposed algorithms
767		and how they scale with dataset size.
768		• If applicable, the authors should discuss possible limitations of their approach to
769		address problems of privacy and fairness.
770		• While the authors might fear that complete honesty about limitations might be used by
771		reviewers as grounds for rejection, a worse outcome might be that reviewers discover
772		limitations that aren't acknowledged in the paper. The authors should use their best
773		judgment and recognize that individual actions in favor of transparency play an impor-
774		tant role in developing norms that preserve the integrity of the community. Reviewers
775		will be specifically instructed to not penalize honesty concerning limitations.
776	3.	Theory Assumptions and Proofs
777		Question: For each theoretical result, does the paper provide the full set of assumptions and
778		a complete (and correct) proof?

779 Answer: [Yes]

780		Justification: See the theoretical result in Appendix 1.
781		Guidelines:
700		• The answer NA means that the paper does not include theoretical results
/82		• The answer two means that the paper does not include theoretical results.
783		• All the theorems, formulas, and proofs in the paper should be numbered and cross-
/84		All account for the should be should be should be stated on an formation the statement of such the summer
785		• All assumptions should be clearly stated or referenced in the statement of any theorems.
786		• The proofs can either appear in the main paper or the supplemental material, but if
787		they appear in the supplemental material, the authors are encouraged to provide a short
788		proof sketch to provide intuition.
789		• Inversely, any informal proof provided in the core of the paper should be complemented
790		by formal proofs provided in appendix of supplemental material.
791		• Theorems and Lemmas that the proof relies upon should be properly referenced.
792	4.	Experimental Result Reproducibility
793		Question: Does the paper fully disclose all the information needed to reproduce the main ex-
794		perimental results of the paper to the extent that it affects the main claims and/or conclusions
795		of the paper (regardless of whether the code and data are provided or not)?
796		Answer: [Yes]
797		Justification: We disclose all the information needed to reproduce the main experimental
798		results of the paper to the extent that it affects the main claims and conclusions of the paper,
799		detailed in Section 3 and Appendix D.1.
800		Guidelines:
801		• The answer NA means that the paper does not include experiments.
802		• If the paper includes experiments, a No answer to this question will not be perceived
803		well by the reviewers: Making the paper reproducible is important, regardless of
804		whether the code and data are provided or not.
805		• If the contribution is a dataset and/or model, the authors should describe the steps taken
806		to make their results reproducible or verifiable.
807		• Depending on the contribution, reproducibility can be accomplished in various ways.
808		For example, if the contribution is a novel architecture, describing the architecture fully
809		might suffice, or if the contribution is a specific model and empirical evaluation, it may
810		be necessary to either make it possible for others to replicate the model with the same
811		dataset, or provide access to the model. In general, releasing code and data is often
812		one good way to accomplish this, but reproducibility can also be provided via detailed
813		of a large language model) releasing of a model abackpoint, or other means that are
814		appropriate to the research performed
010		• While NeurIPS does not require releasing code, the conference does require all submis
815		sions to provide some reasonable avenue for reproducibility, which may depend on the
818		nature of the contribution. For example
819		(a) If the contribution is primarily a new algorithm, the paper should make it clear how
820		to reproduce that algorithm.
821		(b) If the contribution is primarily a new model architecture, the paper should describe
822		the architecture clearly and fully.
823		(c) If the contribution is a new model (e.g., a large language model), then there should
824		either be a way to access this model for reproducing the results or a way to reproduce
825		the model (e.g., with an open-source dataset or instructions for how to construct
826		the dataset).
827		(d) We recognize that reproducibility may be tricky in some cases, in which case
828		authors are welcome to describe the particular way they provide for reproducibility.
829		In the case of closed-source models, it may be that access to the model is limited in
830		some way (e.g., to registered users), but it should be possible for other researchers
831	_	to have some pain to reproducing or verifying the results.
832	5.	Open access to data and code

 Answer: [Yes] Justification: The code is provided in the supplementary marterial. Guidelines: The answer NA means that paper does not include experiments requiring code. Please see the NeuTPS code and data submission guidelines (https://nips.cc/public/guides/CodeSubmissionPolicy) for more details. While we encourage the release of code and data, we understand that this might not be possible, so "No" is an acceptable answer. Papers cannot be rejected simply for not including code, unless this is central to the contribution (e.g., for a new open-source benchmark). The instructions should contain the exact command and environment needed to run to reproduce the results. See the NeurIPS code and data submission guidelines (https://nips.cc/public/guides/CodeSubmissionPolicy) for more details. The authors should provide instructions on data access and preparation, including how to access the raw data, preprocessed data, intermediate data, and generated data, every opsoed method and baselines. If only a subset of experiments are reproducible, they should state which ones are omitted from the script and why. At submission time, to preserve anonymity, the authors should release anonymized versions (if applicable). Providing as much information as possible in supplemental material (appended to the paper) is recommended, but including URLs to data and code is permitted. Experimental Setting/Details Question: Does the paper specify all the training and test details (e.g., data splits, hyper-parameters, how they were chosen, type of optimizer, etc.) necessary to understand the results? The answer NA means that the paper does not include experiments. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	863	Justification: We provide the training and test details Section 3 and Appendix D.1 and
865Guidelines:866• The answer NA means that the paper does not include experiments.867• The experimental setting should be presented in the core of the paper to a level of detail that is necessary to appreciate the results and make sense of them.868• The full details can be provided either with the code, in appendix, or as supplemental material.871 7. Experiment Statistical Significance 872Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments?874Answer: [Yes]875Justification: The proposed method is thoroughly evaluated on three domains, and the results are reported based on a statistical analysis in Section 4 and Appendix E.878• The authors should answer "Yes" if the results are accompanied by error bars, confi- dence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper.882• The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions).	864	Appendix D.2.
 The answer NA means that the paper does not include experiments. The experimental setting should be presented in the core of the paper to a level of detail that is necessary to appreciate the results and make sense of them. The full details can be provided either with the code, in appendix, or as supplemental material. 7. Experiment Statistical Significance Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments? Answer: [Yes] Justification: The proposed method is thoroughly evaluated on three domains, and the results are reported based on a statistical analysis in Section 4 and Appendix E. The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	865	Guidelines:
 The experimental setting should be presented in the core of the paper to a level of detail that is necessary to appreciate the results and make sense of them. The full details can be provided either with the code, in appendix, or as supplemental material. 7. Experiment Statistical Significance Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments? Answer: [Yes] Justification: The proposed method is thoroughly evaluated on three domains, and the results are reported based on a statistical analysis in Section 4 and Appendix E. The answer NA means that the paper does not include experiments. The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	866	• The answer NA means that the paper does not include experiments.
 that is necessary to appreciate the results and make sense of them. The full details can be provided either with the code, in appendix, or as supplemental material. 7. Experiment Statistical Significance Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments? Answer: [Yes] Justification: The proposed method is thoroughly evaluated on three domains, and the results are reported based on a statistical analysis in Section 4 and Appendix E. Guidelines: The answer NA means that the paper does not include experiments. The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	867	• The experimental setting should be presented in the core of the paper to a level of detail
 The full details can be provided either with the code, in appendix, or as supplemental material. 7. Experiment Statistical Significance Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments? Answer: [Yes] Justification: The proposed method is thoroughly evaluated on three domains, and the results are reported based on a statistical analysis in Section 4 and Appendix E. Guidelines: The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	868	that is necessary to appreciate the results and make sense of them.
 7. Experiment Statistical Significance Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments? Answer: [Yes] Justification: The proposed method is thoroughly evaluated on three domains, and the results are reported based on a statistical analysis in Section 4 and Appendix E. Guidelines: The answer NA means that the paper does not include experiments. The authors should answer "Yes" if the results are accompanied by error bars, confi- dence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	869	• The full details can be provided either with the code, in appendix, or as supplemental material
 Provide a statistical significance Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments? Answer: [Yes] Justification: The proposed method is thoroughly evaluated on three domains, and the results are reported based on a statistical analysis in Section 4 and Appendix E. Guidelines: The answer NA means that the paper does not include experiments. The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	870	7 Experiment Statistical Significance
 Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments? Answer: [Yes] Justification: The proposed method is thoroughly evaluated on three domains, and the results are reported based on a statistical analysis in Section 4 and Appendix E. Guidelines: The answer NA means that the paper does not include experiments. The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	8/1	7. Experiment statistical significance
 Answer: [Yes] Justification: The proposed method is thoroughly evaluated on three domains, and the results are reported based on a statistical analysis in Section 4 and Appendix E. Guidelines: The answer NA means that the paper does not include experiments. The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	872 873	Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments?
 Justification: The proposed method is thoroughly evaluated on three domains, and the results are reported based on a statistical analysis in Section 4 and Appendix E. Guidelines: The answer NA means that the paper does not include experiments. The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	070	Answer: [Ves]
 are reported based on a statistical analysis in Section 4 and Appendix E. Guidelines: The answer NA means that the paper does not include experiments. The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	074	Institution: The proposed method is thoroughly evaluated on three domains and the results
 Guidelines: The answer NA means that the paper does not include experiments. The answer NA means that the paper does not include experiments. The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	875	are reported based on a statistical analysis in Section 4 and Appendix E.
 The answer NA means that the paper does not include experiments. The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	877	Guidelines:
 The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	878	• The answer NA means that the paper does not include experiments.
 dence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	879	• The authors should answer "Yes" if the results are accompanied by error bars, confi-
 the main claims of the paper. The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	880	dence intervals, or statistical significance tests, at least for the experiments that support
 The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions). 	881	the main claims of the paper.
run with given experimental conditions).	882	• The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some perspectation or everyll
	884	run with given experimental conditions).

885 886		• The method for calculating the error bars should be explained (closed form formula, call to a library function, bootstrap, etc.)
887		• The assumptions made should be given (e.g., Normally distributed errors).
888		• It should be clear whether the error bar is the standard deviation or the standard error
889		of the mean.
890		• It is OK to report 1-sigma error bars, but one should state it. The authors should
891		preferably report a 2-sigma error bar than state that they have a 96% CI, if the hypothesis
892		of inormality of errors is not verified.
893		• For asymmetric distributions, the authors should be careful not to show in tables or figures symmetric error bars that would yield results that are out of range (e.g. negative
894 895		error rates).
896		• If error bars are reported in tables or plots. The authors should explain in the text how
897	0	they were calculated and reference the corresponding figures or tables in the text.
898	8.	Experiments Compute Resources
899 900 901		Question: For each experiment, does the paper provide sufficient information on the com- puter resources (type of compute workers, memory, time of execution) needed to reproduce the experiments?
902		Answer: [Yes]
903		Justification: The detailed configuration of the experiments is listed with required computa-
904		tional resources.
905		Guidelines:
906		 The answer NA means that the paper does not include experiments.
907		• The paper should indicate the type of compute workers CPU or GPU, internal cluster,
908		or cloud provider, including relevant memory and storage.
909		• The paper should provide the amount of compute required for each of the individual avarianted runs as well as estimate the total compute
910		• The paper should disclose whether the full research project required more compute
912		than the experiments reported in the paper (e.g., preliminary or failed experiments that
913		didn't make it into the paper).
914	9.	Code Of Ethics
915		Question: Does the research conducted in the paper conform, in every respect, with the
916		NeurIPS Code of Ethics https://neurips.cc/public/EthicsGuidelines?
917		Answer: [Yes]
918 919		Justification: We confirm that the research conducted in the paper conform, in every respect, with the NeurIPS Code of Ethics, and all the authors preserve anonymity.
920		Guidelines:
921		• The answer NA means that the authors have not reviewed the NeurIPS Code of Ethics.
922		• If the authors answer No, they should explain the special circumstances that require a
923		deviation from the Code of Ethics.
924		• The authors should make sure to preserve anonymity (e.g., if there is a special consid-
925		eration due to laws or regulations in their jurisdiction).
926	10.	Broader Impacts
927 928		Question: Does the paper discuss both potential positive societal impacts and negative societal impacts of the work performed?
929		Answer: [Yes]
930		Justification: The broader impacts of our paper are presented in Section F.1.
931		Guidelines:
932		• The answer NA means that there is no societal impact of the work performed
933		• If the authors answer NA or No. they should explain why their work has no societal
934		impact or why the paper does not address societal impact.

935 936 937 938		• Examples of negative societal impacts include potential malicious or unintended uses (e.g., disinformation, generating fake profiles, surveillance), fairness considerations (e.g., deployment of technologies that could make decisions that unfairly impact specific groups), privacy considerations, and security considerations.
939		• The conference expects that many papers will be foundational research and not tied
940		to particular applications, let alone deployments. However, if there is a direct path to
941		any negative applications, the authors should point it out. For example, it is legitimate
942		to point out that an improvement in the quality of generative models could be used to
0/3		generate deepfakes for disinformation. On the other hand, it is not needed to point out
044		that a generic algorithm for ontimizing neural networks could enable neonle to train
944		models that generate Deenfakes faster
940		The development of the second state of the sec
946		• The authors should consider possible harms that could arise when the technology is
947		being used as intended and functioning correctly, harms that could arise when the
948		technology is being used as intended but gives incorrect results, and harms following
949		from (intentional or unintentional) misuse of the technology.
950		• If there are negative societal impacts, the authors could also discuss possible mitigation
951		strategies (e.g., gated release of models, providing defenses in addition to attacks,
952		mechanisms for monitoring misuse, mechanisms to monitor how a system learns from
953		feedback over time, improving the efficiency and accessibility of ML).
954	11.	Safeguards
955		Question: Does the paper describe safeguards that have been put in place for responsible
956		release of data or models that have a high risk for misuse (e.g., pretrained language models,
957		image generators, or scraped datasets)?
958		Answer: [NA]
959		Justification: Our paper poses no such risks.
960		Guidelines:
961		• The answer NA means that the paper poses no such risks.
962		• Released models that have a high risk for misuse or dual-use should be released with
963		necessary safeguards to allow for controlled use of the model, for example by requiring
964		that users adhere to usage guidelines or restrictions to access the model or implementing
965		safety filters.
966		• Datasets that have been scraped from the Internet could pose safety risks. The authors
967		should describe how they avoided releasing unsafe images.
968		• We recognize that providing effective safeguards is challenging, and many papers do
969		not require this, but we encourage authors to take this into account and make a best
970		faith effort.
971	12.	Licenses for existing assets
972		Question: Are the creators or original owners of assets (e.g., code, data, models), used in
973		the paper, properly credited and are the license and terms of use explicitly mentioned and
974		properly respected?
975		Answer: [Yes]
076		Justification: All the assets used in our paper, are properly credited and we explicitly
977		mention and properly respect the license and terms of use.
978		Guidelines:
979		• The answer NA means that the paper does not use existing assets.
980		• The authors should cite the original paper that produced the code package or dataset.
0.91		• The authors should state which version of the asset is used and if nossible include a
000		I ne autors should state which version of the asset is used and, it possible, include a
55 <u>2</u>		The name of the linear $(z = OO DV A 0)$ is 111. $(z = 1, 1, 1, 0)$
983		• The name of the license (e.g., CC-BY 4.0) should be included for each asset.
984 985		• For scraped data from a particular source (e.g., website), the copyright and terms of service of that source should be provided.

986 987 988 989		• If assets are released, the license, copyright information, and terms of use in the package should be provided. For popular datasets, paperswithcode.com/datasets has curated licenses for some datasets. Their licensing guide can help determine the license of a dataset.
990 991		• For existing datasets that are re-packaged, both the original license and the license of the derived asset (if it has changed) should be provided.
992 993		• If this information is not available online, the authors are encouraged to reach out to the asset's creators.
994	13.	New Assets
995 996		Question: Are new assets introduced in the paper well documented and is the documentation provided alongside the assets?
997		Answer: [NA]
998		Justification: This paper does not release new assets.
999		Guidelines:
1000		• The answer NA means that the paper does not release new assets
1000		 Researchers should communicate the details of the dataset/code/model as part of their
1001 1002 1003		submissions via structured templates. This includes details about training, license, limitations, etc.
1004		• The paper should discuss whether and how consent was obtained from people whose
1005		asset is used.
1006 1007		• At submission time, remember to anonymize your assets (if applicable). You can either create an anonymized URL or include an anonymized zip file.
1008	14.	Crowdsourcing and Research with Human Subjects
1009		Question: For crowdsourcing experiments and research with human subjects, does the paper
1010		include the full text of instructions given to participants and screenshots, if applicable, as
1011		well as details about compensation (if any)?
1012		Answer: [NA]
1013		Justification: Our paper does not involve crowdsourcing nor research with human subjects.
1014		Guidelines:
1015		• The answer NA means that the paper does not involve crowdsourcing nor research with
1016		human subjects.
1017		• Including this information in the supplemental material is fine, but if the main contribu-
1018		tion of the paper involves human subjects, then as much detail as possible should be
1019		included in the main paper.
1020		• According to the NeurIPS Code of Ethics, workers involved in data collection, curation,
1021		collector
1000	15	Institutional Deview Roard (IDR) Approvals or Equivalent for Desearch with Human
1023	15.	Subjects
1025		Question: Does the paper describe potential risks incurred by study participants, whether
1026		approvals (or an equivalent approval/review based on the requirements of your country or
1028		institution) were obtained?
1029		Answer: [NA]
1030		Justification: Our paper does not involve crowdsourcing nor research with human subjects.
1031		Guidelines:
1032		• The answer NA means that the paper does not involve crowdsourcing nor research with
1033		human subjects.
1034		• Depending on the country in which research is conducted, IRB approval (or equivalent)
1035 1036		may be required for any human subjects research. If you obtained IRB approval, you should clearly state this in the paper.

1037	• We recognize that the procedures for this may vary significantly between institutions
1038	and locations, and we expect authors to adhere to the NeurIPS Code of Ethics and the
1039	guidelines for their institution.
1040	• For initial submissions, do not include any information that would break anonymity (if
1041	applicable), such as the institution conducting the review.
