# Mitigating Language Biases In Visual Question Answering Through The Forgotten Attention Algorithm

Anonymous ACL submission

#### Abstract

 At present, in the field of Visual Question An- swering (VQA), a model's ability to compre- hend various modalities is crucial for accu- rate answer reasoning. However, recent stud- ies have uncovered prevailing language biases in VQA, where reasoning frequently relies on incorrect associations between questions and answers, rather than genuine multi-modal knowledge-based reasoning. Thus, it is of great challenge to reveal the accurate relationship between image and question. The key idea of this work is inspired by the process of an- swering questions of human beings, where peo- ple always gradually reduce the focus area in the image with the aid of question information until the final related area is retained. More 017 specifically, we introduce a novel attention al-018 gorithm, named the Forgotten Attention Algo-**rithm (FAA), where this algorithm gradually**  "forgets" some visual contents after several rounds. This deliberate forgetting process con- centrates the model's "attention" on the image region that is the most relevant to the ques- tion. As a result, it can enhance the integra- tion of image content and thus mitigate lan- guage biases. We conducted comprehensive 027 experiments on the VQA-CP v2, VQA v2, and VQA-VS datasets to validate the efficiency and robustness of the algorithm.

#### **030** 1 Introduction

 In recent years, Visual Question Answering (VQA) has become one of the prominent tasks in the field of deep learning [\(Hudson and Manning,](#page-7-0) [2019a\)](#page-7-0), achieving significant accomplishments in various applications, such as intelligent service systems [\(Luo et al.,](#page-8-0) [2023;](#page-8-0) [Wang et al.,](#page-8-1) [2022\)](#page-8-1). However, recent research has found that many existing VQA methods tend to rely on false associations between questions and answers, without sufficiently extract- ing accurate visual information from images to answer questions. For example, when answering questions "What color?", some VQA models are **042** inclined to use the most common answers from **043** training data of that type, like "yellow," rather than **044** extracting genuine color information from images. **045** Additionally, some studies [\(et al.,](#page-7-1) [2021;](#page-7-1) [Liu et al.,](#page-8-2) 046 [2022\)](#page-8-2) have indicated deficiencies in the existing **047** methods' understanding of images, resulting in an- **048** swers generated by the model relying on image  $049$ regions with low relevance to the questions. In **050** other words, specific methods often provide correct **051** answers based on incorrect image regions, which **052** does not genuinely reflect the model's performance **053** in the question-answering task. Consequently, the **054** factors affecting the robustness of VQA models can **055** be summarized into two primary aspects: inherent **056** biases in the language distribution of training and **057** testing datasets, and the improper shortcut biases **058** caused by the inadequate utilization of visual infor- **059** mation [\(Liu et al.,](#page-8-3) [2023\)](#page-8-3).

The state-of-the-art and noteworthy methods **061** primarily revolve around data augmentation tech- **062** niques and attention-based approaches. Data aug- **063** mentation methods [\(Chen et al.,](#page-7-2) [2020\)](#page-7-2) aim to en- **064** hance a model's understanding of critical features **065** within the data by expanding the dataset with samples, such as counterfactual instances and addi- **067** [t](#page-7-3)ional annotations [\(Liang et al.,](#page-8-4) [2020;](#page-8-4) [Gokhale et](#page-7-3) **068** [al.,](#page-7-3) [2020\)](#page-7-3), which help eliminate biases and enhance **069** robustness [\(Agarwal,](#page-7-4) [2020;](#page-7-4) [Wen et al.,](#page-8-5) [2021\)](#page-8-5) by **070** obtaining more critical sample features and supple- **071** mentary information. However, it is still of great in- **072** terest and challenge to remove the language biases **073** in VQA model without resorting to data augmenta- **074** tion [\(Niu et al.,](#page-8-6) [2021\)](#page-8-6). Regarding attention-based **075** methods[\(et al.,](#page-7-5) [2017\)](#page-7-5), the majority currently integrate these into pre-trained models for efficient **077** feature fusion [\(Tan and Bansal,](#page-8-7) [2019;](#page-8-7) [Yu et al.,](#page-8-8) **078** [2019;](#page-8-8) [Lu et al.,](#page-8-9) [2016;](#page-8-9) [Lu et al.,](#page-8-10) [2022;](#page-8-10) [Anderson,](#page-7-6) **079** [2018\)](#page-7-6), with limited emphasis on fully utilizing vi- **080** sual information. **081** 

Therefore, we believe that effectively utilizing **082**

<span id="page-1-0"></span>

**What are the people doing?**

**Wrong Answer: Sitting**

**Right Answer: Cycling**

Figure 1: Due to the presence of biases, the influence of the size of prominent objects in the image on model reasoning leads to incorrect answers, while the image regions relevant to the answers often occupy a small portion. FAA achieves this by masking irrelevant regions in the image, allowing the model to focus on image details for inference.

 image content without data augmentation is an ef- fective approach to mitigating language biases. In Fig. [1,](#page-1-0) it is evident that prominent objects (i.e., the bench) often dominate the model's attention, causing it to overlook the finer image area that is relevant to the question (i.e., the people). This ob- servation poses a new challenge: how to focus on the right image area that is the most relevant to the question. To address this problem, we are inspired by the process of answering questions of human beings, where people always gradually reduce the focus area in the image with the aid of question information until the final related area is retained.

 In this paper, specifically, we introduce a novel attention algorithm, named the Forgotten Atten- tion Algorithm (FAA), where this algorithm iter- atively "forgets" some visual contents after each round, that is, disregarding irrelevant image infor- mation. Through multiple iterations, the model pro- gressively identifies more relevant regions within the image. As shown in Fig. [1,](#page-1-0) FAA gradually masks less relevant regions, resulting in effectively harnessing related image information. The retained image is then utilized for the final answer reason- ing, thus alleviating the influence of salient objects in the image that are not related to the question.

**109** Overall, this paper's contributions are delineated **110** as follows:

 1. We introduce a novel forgetfulness attention algorithm (FAA) aimed at mitigating biases in VQA. The FAA achieves robust VQA by focusing on forgetting unimportant informa- tion and reinforcing the role of correct visual content in reasoning.

**117** 2. On VQA-CP v2, our enhancements in lever-**118** aging visual information led to optimal performance. Notably, without additional anno- **119** tations, our approach attained a 20.78% im- **120** provement compared to the UpDn baseline **121** model. Code is available at:[https://github.](https://github.com/EASONGLLL/FAA-VQA) **122** [com/EASONGLLL/FAA-VQA](https://github.com/EASONGLLL/FAA-VQA). **123**

#### 2 Related work **<sup>124</sup>**

#### 2.1 Visual Question Answering **125**

The VQA task demands accurate model responses **126** to image-related questions. Since its inception, this **127** field has seen the emergence of various pertinent **128** datasets and multimodal fusion techniques, such **129** [a](#page-7-8)s VQA v2[\(Antol et al.,](#page-7-7) [2015\)](#page-7-7), GQA[\(Hudson and](#page-7-8) **130** [Manning,](#page-7-8) [2019b\)](#page-7-8), CLEVR[\(Johnson et al.,](#page-8-11) [2016\)](#page-8-11), **131** [O](#page-8-13)K-VQA[\(Marino et al.,](#page-8-12) [2019\)](#page-8-12), and VideoQA[\(Tu](#page-8-13) **132** [et al.,](#page-8-13) [2013\)](#page-8-13) rooted in video datasets. Presently, **133** methods based on single-stream and dual-stream **134** architectures[\(Yang et al.,](#page-8-14) [2019;](#page-8-14) [Wang et al.,](#page-8-15) [2019;](#page-8-15) **135** [Izacard and Grave,](#page-7-9) [2021;](#page-7-9) [Rajpurkar et al.,](#page-8-16) [2018;](#page-8-16) **136** [Chen et al.,](#page-7-10) [2020\)](#page-7-10) achieve high accuracy by exten- **137** sively pretraining on abundant samples.

#### 2.2 Language Bias **139**

In recent research, researchers have proposed a **140** range of debiasing methods to address language **141** bias concerning existing defined bias issues. These **142** [m](#page-8-17)ethods include adversarial-based techniques [\(Ra-](#page-8-17) **143** [makrishnan et al.,](#page-8-17) [2018\)](#page-8-17), regularization approaches **144** [\(Niu et al.,](#page-8-6) [2021;](#page-8-6) [Han et al.,](#page-7-11) [2021;](#page-7-11) [Abbasnejad](#page-7-12) **145** [et al.,](#page-7-12) [2020;](#page-7-12) [Cho et al.,](#page-7-13) [2023;](#page-7-13) [Basu et al.,](#page-7-14) [2023\)](#page-7-14), **146** and data augmentation strategies [\(Chen et al.,](#page-7-2) [2020;](#page-7-2) **147** [Wen et al.,](#page-8-5) [2021\)](#page-8-5). Our approach focuses on address- 148 ing bias issues from the perspective of the visual **149** modality. **150**

 tion mechanisms into debiasing methods in VQA, strengthening the model's retrieval capabilities be- tween images and questions. Leveraging attention mechanisms enhances the role of visual informa-

**166** tion, ultimately aiding in debiasing strategies.

 In the context of Visual Question Answering (VQA), attention mechanisms are employed to inte- grate information from different modalities [\(et al.,](#page-7-5) [2017\)](#page-7-5), allowing models to focus on the most rele- vant regions between images and texts. Presently, attention-based methodologies include linear atten- tion [\(et al.,](#page-7-15) [2016\)](#page-7-15), co-attention [\(Lu et al.,](#page-8-9) [2016\)](#page-8-9), detection attention [\(et al.,](#page-7-5) [2017\)](#page-7-5), and relational attention [\(Wu et al.,](#page-8-18) [2018\)](#page-8-18). Consequently, in our approach, we explore the integration of atten-

## **<sup>167</sup>** 3 Method

**151** 2.3 Attention Mechanism

 We now describe the architecture and algorithmic flow of FAA. As shown in Fig. [2,](#page-3-0) the left side illus- trates the primary structure of the UpDn baseline model [\(Anderson,](#page-7-6) [2018\)](#page-7-6), responsible for extract- ing visual-language features. On the right side, 173 there are stacked *Attention Layers* that itera- tively mask irrelevant features and make answer predictions.

## **176** 3.1 Visual Information Combination

177 On the left side of Fig. [2,](#page-3-0) we utilize the UpDn **178** encoding layer to extract features. For a given text, **179** the UpDn leverages a standard GRU to encode each **180** question, generating a question vector. Regarding **181** the provided image, UpDn uses the detected visual **182** features as input. The visual feature set is repre-183 sented as  $F = \{f_1, ., f_i, ., f_n\}$ , where  $f_i$  denotes 184 the feature of the *i*-th object in the image. In our **185** method, we also incorporate factors such as spatial **186** position. We re-encode all the outputs from Faster-187 RCNN [\(Ren et al.,](#page-8-19) [2017\)](#page-8-19) into new visual features. 188 The visual input V is represented as Eq. [\(1\)](#page-2-0),

<span id="page-2-0"></span>
$$
V = Visual\_Encoder(F, S, Cls, Ari), \quad (1)
$$

190 where *V* isual *Encoder* represents the visual en- coder responsible for re-encoding the four types of features into visual input. These four types of features are represented as visual feature vectors F, spatial features S, classification scores Cls, and attribute information Ari. During the initialization phase, this re-encoded visual data V is introduced as the visual input for the VQA process.

Algorithm 1: Forgetting Attention Algo-

<span id="page-2-1"></span>rithm Input :Representation of Object Detection Outputs:  $\mathcal{F}, \mathcal{S}, Cls, Ari;$ Text coded representation:Q; Number of layers of attention stack: $N$ ; Attention threshold: $\alpha$ . Output :Predicted answer probability:A.

Initialize:  $V \leftarrow [\mathcal{F}, \mathcal{S}, Cls, Ari], k \leftarrow 3$ .

Function  $FAA(V, Q)$ : while  $n \leq N$  do  $att_v, att_q \leftarrow SelfAttention(V, Q)$  $V^1, Q^1 \leftarrow att_v \odot V, att_q \odot Q$  $V^2, Q^2 \leftarrow$  $CrossAttention(V^1, Q^1)$  $Att \leftarrow V^2 \odot Q^2$ if  $Att \leq \alpha$  then  $V_{mask} \leftarrow 1;$ else  $V_{mask} \leftarrow 0;$  $V^3 \leftarrow V_{mask} \oplus V^2$  $V, Q \leftarrow V^3, Q^2$  $\mathcal{A} \leftarrow V^3, Q^2$ return A

#### 3.2 Attention Layers **198**

In the right side of Fig. [2,](#page-3-0) we have stacked N **199** layers of Attention\_Layer to achieve visual in- **200** formation masking and retrieval. Specifically, the **201** Attention Layer module consists of three main 202 components: **203**

1. Initial Impression. After obtaining visual and **204** text features, the next step in our process is **205** to employ the Self\_Attention mechanism. **206** This mechanism helps identify the most criti- **207** cal components within each modality, similar **208** to how humans instinctively react when first **209** encountering an image or text. We establish **210** the model's initial assessment of the pivotal **211** image regions and word vectors within the **212** provided features. As shown in Algorithm [1,](#page-2-1) **213** it is defined as follows, **214**

$$
att_v = Self(V),
$$
  
\n
$$
att_q = Self(Q),
$$
  
\n
$$
V^1 = att_v * V,
$$
  
\n
$$
Q^1 = att_q * Q,
$$
  
\n(2) 215

where  $att_v$  and  $att_q$  represent the initial at-  $216$ tention.  $V^1$  and  $Q^1$  represent the features ob- 217

<span id="page-3-0"></span>

Figure 2: Our proposed FAA follows the architecture of the UpDn baseline model, comprising the feature extraction stage of the UpDn model and the attention layers. The attention layers aim to retrieve information from the encoded question and image features, facilitating a multi-round retrieval process. In each round of retrieval, an image mask matrix is constructed to mask out the information deemed irrelevant by the model during this round, retaining crucial information for subsequent reasoning.

**218** tained after fusing the initial attention with the **219** original data.

 2. Cross-Modal Retrieval. With the obtained features  $V^1$  and  $Q^1$ , we consider using the Cross\_Attention mechanism [\(Tan and](#page-8-7) [Bansal,](#page-8-7) [2019\)](#page-8-7) to explore information across modalities. This step is analogous to how humans associate objects with words. We per- form cross-modal information retrieval sepa- rately in the image and text domains. This is defined as Eq. [\(3\)](#page-3-1),

<span id="page-3-1"></span>229  
\n
$$
V^{2} = CrossAtt_{v \to q}(Q^{1}, V^{1}),
$$
\n
$$
Q^{2} = CrossAtt_{q \to v}(V^{1}, Q^{1}),
$$
\n(3)

230 where  $V^2$  and  $Q^2$  represent the feature out- puts after conducting cross-modal retrieval for the image and text, respectively. Cross\_Att respectively represents the cross-modal infor- mation retrieval layer, with 'image' and 'ques-tion' as the primary modalities.

 3. Masking Matrix. After cross-modal retrieval, 237 we calculate the masking matrix for  $V^2$  and  $Q^2$ . Initially, we employ the Top-Down atten- tion mechanism [\(Anderson,](#page-7-6) [2018\)](#page-7-6) to obtain an attention weight matrix Att, which is then 241 compared to a predefined threshold  $\alpha$  to de- termine the masking matrix. As depicted in Algorithm [1,](#page-2-1) this is defined as Eq. [\(4\)](#page-3-2),

<span id="page-3-2"></span>
$$
Att = V^2 * Q^2,
$$
  
\n
$$
V_{mask} = Mask(Att \le \alpha),
$$
  
\n
$$
V^3 = V_{mask} \oplus V^2,
$$
  
\n(4)

where  $V_{mask}$  represents the masking matrix, 245 and  $Mask()$  denotes the process in which  $Att$  246 is compared to  $\alpha$  in Algorithm [1.](#page-2-1) The value 247 of  $\alpha$  is determined by the mean of attention.  $248$ V 3 represents the features obtained by merg- **249** ing the masking matrix with visual features. **250** ⊕ denotes the linear fusion of two types of **251** features. **252**

Specifically, in each Attention\_Layer, we es- **253** tablish a masking matrix based on the magnitude **254** of attention weights, which masks regions in the **255** image that contribute less to the answer. Through **256** N such Attention\_Layers, we allow the model **257** to progressively identify precise regions with high **258** relevance to the given question. **259**

## 4 Experiments **<sup>260</sup>**

#### 4.1 Comparisons with State-of-the-Arts **261**

The experimental results on the VQA-CP v2, VQA 262 v2 and VQA-VS[\(Si et al.,](#page-8-20) [2022\)](#page-8-20) dataset are dis- **263** played in Table [1](#page-4-0) and Table [2.](#page-5-0) Within the table, we **264** list some excellent debiasing endeavors for com- **265** parison. **266**

- 1. We evaluate our approach on three baseline **267** models (UpDn and RUBi), achieving enhance- **268** ments of approximately 19% and 13% com- **269** pared to these models. **270**
- 2. When compared to other attention-based **271** (SCR, AttAlign, HINT) debiasing methods **272** using the same baseline model, our approach **273** delivers performance enhancements in ques- **274** tion types requiring more extensive visual in- **275**

**276** formation, particularly in "Num." and "Other" **277** question types.

- **278** 3. We extend the application of FAA to data aug-**279** mentation methods like CSS, resulting in per-**280** formance enhancement when combined with **281** CSS.
- **282** 4. FAA consistently maintains stability and ex-**283** hibits a certain level of precision and general-**284** ization on the VQA v2 dataset.
- **285** 5. Within the VQA-VS dataset, FAA demon-**286** strates distinct advantages over models em-**287** ploying the same baseline. Additionally, FAA **288** exhibits considerable performance when han-**289** dling a broader spectrum of bias types.

## **290** 4.2 Qualitative results

 As depicted in Figure [3,](#page-5-1) the original image, after two rounds of attentional operations, masks out irrelevant areas based on attentional weights in the (1), ultimately identifying the target region relevant to the answer.

In Figure [3,](#page-5-1) more examples are given to ana- **296** lyze the effect of forgotten attention on changes **297** in image areas. For example, in the example of **298** the (2), the image of the animal is the area where **299** the zebra is located, and there is overlap between **300** some areas that are unrelated to the problem and  $301$ the zebra, which is covered by the FAA to some **302** extent, but most of the zebra area is still captured **303** by the model. Similarly, in the (3) and (4), the areas **304** of the sign is somewhat obscured, but the model **305** still understands the semantics of the remaining **306** areas of the image and gives the correct answer. **307** In the (5), the final answer area is well preserved **308** due to the size of the relevant image area. In the **309** (6), we give an error example. Although the model **310** correctly answers the relevant questions, the model **311** still locates the wrong image region due to similar **312** semantic information in the image. 313

## 4.3 Abalation Experiments **314**

Forgotten Sequence The concept of forgetting at- **315** tention in this paper is based on the process of **316** human answering relevant questions. The ablation **317**

<span id="page-5-0"></span>Table 2: Regarding the experimental outcomes of FAA on the VQA-VS dataset, we have presented the relevant experimental performance reports associated with this dataset. Each column displays the performance results of the corresponding best and second-performing models.

Thresholds Base All Y/N Num. Other						
0.5			UpDn 56.84 83.29 43.87 46.54			
0.6			UpDn 60.74 83.99 41.45 53.85			
0.7			UpDn 59.75 82.85 35.21 54.38			

model first notices the areas of the image that **328** are less relevant to the problem, assigns higher **329** weights to them, and finally forgets the areas **330** of the image with lower weights. **331**

3. The feature areas in the image are arranged in **332** the original linear order, and the model forgets **333** the relevant features in the same order. **334**

By comparing the model performance of differ- **335** ent forgetting sequences, we were able to observe **336** that the FAA achieved excellent performance by **337** forgetting irrelevant regions, while the other forget- **338** ting sequences resulted in decreased performance. **339** This suggests that the human attentional forgetting **340** mechanism on which the FAA is based works. 341

Attention Threshold Selection In this method, **342** we set thresholds to allow the model to filter im- **343** age regions to determine which are forgotten and **344** which are retained. Different threshold sizes make  $345$ the model achieve different performance when for- **346** getting the image region. If the threshold is too **347** high, the model will forget most of the image re- **348** gion, resulting in the model being unable to obtain **349** useful information from the image, while if the **350** threshold is too low, the model will retain useless **351** information, thus degrading the algorithm to a com- **352** mon attention algorithm. Therefore, this section **353** sets up a comparative analysis of different thresh- **354** old sizes to determine the appropriate parameter as **355**

<span id="page-6-0"></span>

	Visual		Spatial CLS Attribute	All	Method	
				56.34	Q-CSS	56
2				55.30	<b>CSS</b>	58
3				54.53	FAA+Q-CSS	-58

<span id="page-6-1"></span>Table 6: The performance under different number of attention layers.

4  $\checkmark$   $\checkmark$   $\checkmark$  59.02

**356** the forgetting threshold. As shown in the table [4,](#page-5-2) **357** the corresponding experimental results of the three **358** threshold sizes selected by us are reported.

 Considering the three different choices of atten- tion threshold, in the original attention scheme of UpDn, the contribution degree of different image regions to the answer is realized by the assigned weight, whose value is between 0 and 1. Therefore, we choose the sizes of 0.5, 0.6 and 0.7 for experi- mental comparison. The final experimental results show that when the threshold size is 0.6, the ex- perimental effect reaches the optimal performance, and the forgetting ability of the model reaches the equilibrium.

 Visual Information. As shown in Table [5,](#page-6-0) In our method, the output after Faster RCNN detection is combined as the visual input of the model in this paper. Specifically, we fuse each of the four com- binations as new visual feature inputs, confirming the benefit of diverse visual information in model comprehension.

 Layers Of Attention. As shown in Table [6,](#page-6-1) We set up different levels of attention in the method to perform validation experiments. Specifically, when humans answer questions by focusing on dif- ferent areas in the image, they may go through multiple target shifts to determine the final area, while in the simulation of a computer, this oper- ation can be achieved by setting the number of layers of attention. In this experiment, we set up a total of five different layers, as you can see the model performs the best with three attention layers.

<span id="page-6-2"></span>Table 7: Ablation experiments involving FAA and the CSS method

Method	AII	Yes/No	Num.	Other
Q-CSS	56.19	80.83	40.33	47.63
<b>CSS</b>	58.17	84.57	46.99	47.40
FAA+Q-CSS	58.31	80.83	48.90	49.10
<b>FAA+CSS</b>	60.09	88.55	53.16	47.09

<span id="page-6-3"></span>Table 8: Experiment on the evaluation metric CGD using the FAA method on the VQA-CP v2 dataset. Best results are displayed in each column.

This configuration significantly improves perfor- **388** mance during inference compared to fewer layers. **389** However, increasing the number of layers yields a **390** slightly worse overall accuracy as well as increas- **391** ing inference time by nearly 200 seconds. Thus, **392** we settle on three attention layers. Regarding accu- **393** racy degradation, we believe that this phenomenon **394** arises due to the fact that the model recognizes **395** incorrect visual information and masks relevant **396** regions, thus hindering accurate answer retrieval. **397**

Q-CSS. In our approach, we opted for a single- **398** word replacement strategy, combined with FAA. **399** The experimental results in Table [7](#page-6-2) encompass a 400 partial replication of the Q-CSS strategy from the **401** CSS method and the QV-CSS strategy, incorporat- **402** ing FAA into both Q-CSS and CSS. Notably, our **403** approach exhibits approximately 2% improvement **404** in accuracy over Q-CSS and CSS. 405

#### 4.4 Analysis of Other Metrics **406**

In our approach, we aim to increase the role of  $407$ visual content in reasoning. To assess its effective- **408** ness, we use additional metrics. In Table [8,](#page-6-3) we **409** compare our results with other methods using the **410** CGD metric. For a more detailed understanding of **411** [C](#page-8-21)GD, please refer to [\(Han et al.,](#page-7-11) [2021;](#page-7-11) [Shrestha et](#page-8-21) **412** [al.,](#page-8-21) [2020\)](#page-8-21). Compared to GGE[\(Han et al.,](#page-7-11) [2021\)](#page-7-11), **413** our approach performs better in terms of CGD, in- **414** dicating improved utilization of visual information **415**

- **416** for answer prediction.

## **<sup>417</sup>** 5 Conclusion

 In this paper, we introduce a novel attention mecha- nism, the Forget Attention Algorithm (FAA), aimed at mitigating language bias. We regard language bias as a lack of model comprehension of visual content. We artificially mask the image content in our method using a "forgetting" strategy, enabling the model to mimic human attention flow in each iteration for multi-step reasoning. We experiment with our method on datasets VQA v2, VQA-CP v2, and VQA-VS to validate its effectiveness.

# **<sup>428</sup>** 6 Limitations

<span id="page-7-16"></span>

Figure 4: The answer is correct but relies on incorrect visual content.

 Firstly, as shown in the Fig. [4,](#page-7-16) the limitations of the forgetting attention are reflected in the reliance on model knowledge during prediction. When the contents of the images are similar and the model fails to notice detailed information, it focuses on incorrect areas. Secondly, if the model focuses on the wrong areas in the initial rounds, subsequent corrections cannot be effectively made. The model will continue to search for answers within these incorrect regions.
