

Wasserstein Convergence of Score-based Generative Models under Semiconvexity and Discontinuous Gradients

Anonymous authors

Paper under double-blind review

Abstract

Score-based Generative Models (SGMs) approximate a data distribution by perturbing it with Gaussian noise and subsequently denoising it via a learned reverse diffusion process. These models excel at modeling complex data distributions and generating diverse samples, achieving state-of-the-art performance across domains such as computer vision, audio generation, reinforcement learning, and computational biology. Despite their empirical success, existing Wasserstein-2 convergence analysis typically assume strong regularity conditions—such as smoothness or strict log-concavity of the data distribution—that are rarely satisfied in practice. In this work, we establish the first non-asymptotic Wasserstein-2 convergence guarantees for SGMs targeting semiconvex distributions with potentially discontinuous gradients. Our upper bounds are explicit and sharp in key parameters, achieving optimal dependence of $O(\sqrt{d})$ on the data dimension d and convergence rate of order one. The framework accommodates a wide class of practically relevant distributions, including symmetric modified half-normal distributions, Gaussian mixtures, double-well potentials, and elastic net potentials. By leveraging semiconvexity without requiring smoothness assumptions on the potential such as differentiability, our results substantially broaden the theoretical foundations of SGMs, bridging the gap between empirical success and rigorous guarantees in non-smooth, complex data regimes.

1 Introduction

Score-based Generative Models (SGMs), also known as diffusion-based generative models (Song & Ermon, 2019; Song et al., 2021; Sohl-Dickstein et al., 2015; Ho et al., 2020), have rapidly emerged over the past few years as a popular approach in modern generative modelling due to their remarkable capabilities in generating complex data, surpassing previous state-of-the-art models, such as Generative Adversarial Networks (GANs) (Goodfellow et al., 2014) and Variational AutoEncoders (VAEs) (Kingma & Welling, 2014). These models are now widely adopted in computer vision and audio generation tasks (Kong et al., 2020; Chen et al., 2021; Mittal et al., 2021; Avrahami et al., 2021; Kim et al., 2021; Bansal et al., 2023; Saharia et al., 2022; Po et al., 2023; Zhang et al., 2023), text generation (Li et al., 2022; Yu et al., 2022; Lovelace et al., 2023), sequential data modeling (Alcaraz & Strodthoff, 2023; Tashiro et al., 2021; Tevet et al., 2023), reinforcement learning and control (Pearce et al., 2023; Chi et al., 2023; Hansen-Estruch et al., 2023; Reuss et al., 2023; Zhu et al., 2023; Ding & Jin, 2024), as well as life-science (Chung & Ye, 2021; Jing et al., 2022; Watson et al., 2023; Song et al., 2022; Weiss et al., 2023). We refer the reader to the survey papers Yang et al. (2023); Chen et al. (2024) for a more comprehensive exposition of their applications.

The primary goal of SGMs is to generate synthetic data that closely match a target data distribution π_D , given a sample set. In particular, these models generate approximate data samples from high-dimensional data distributions by combining two diffusion processes, a forward and a backward process in time. The forward process is used to iteratively and smoothly transform samples from the unknown data distribution into (Gaussian) noise, while the associated backward process reverses the noising procedure to generate new samples from the starting unknown data distribution. A key role in these models is played by the score function, i.e. the gradient of the log-density of the solution of the forward process, which appears in the drift of the stochastic differential equation (SDE) associated with the backward process. Since this quantity

depends on the unknown data distribution, an estimator of the score must be constructed during the noising step using score-matching techniques (Hyvärinen, 2005; Vincent, 2011).

The widespread applicability and success of SGMs have been accompanied by a growing interest in the theoretical understandings of these models, particularly in the convergence analysis under different metrics such as Total Variation (TV) distance, Kullback Leibler (KL) divergence, Wasserstein distance, e.g., Block et al. (2020); De Bortoli et al. (2021); Bortoli (2022); Lee et al. (2022); Yang & Wibisono (2022); Kwon et al. (2022); Liu et al. (2022); Oko et al. (2023); Lee et al. (2023); Chen et al. (2023a,b); Li et al. (2024); Pedrotti et al. (2024); Conforti et al. (2025); Benton et al. (2024); Strasman et al. (2025); Bruno et al. (2025); Tang & Zhao (2024); Mimikos-Stamatopoulos et al. (2024); Gentiloni-Silveri & Ocello (2025); Yu & Yu (2025). In this work, we provide a non-asymptotic convergence analysis in Wasserstein distance of order two, as this metric is often considered more practical and informative for estimation tasks (see e.g., equation 5), and is closely connected to the popular Fréchet Inception Distance (FID) used to assess the quality of images in generative modeling (see, e.g., Section 4). A significant limitation of prior analysis in Wasserstein-2, e.g., Strasman et al. (2025); Gao et al. (2025); Bruno et al. (2025); Tang & Zhao (2024); Yu & Yu (2025), is their reliance on strong regularity conditions—such as smoothness or strict log-concavity—of the data distribution and its potential. These assumptions facilitate mathematical tractability but limit the applicability of theoretical results to more general settings, especially when the data distribution is only semiconvex and the potential’s gradient may be discontinuous. The only exception outside the strict log-concavity regime is the recent contribution in Gentiloni-Silveri & Ocello (2025), where the authors assumes that the data distribution is weakly convex. However, their analysis still requires the potential to be twice continuously differentiable (see, e.g., Gentiloni-Silveri & Ocello (2025, Proofs of Propositions B.1 and B.2)), and the stepsize of their generative algorithm must be bounded by a quantity inversely proportional to the one-sided Lipschitz constant of the potential (see Gentiloni-Silveri & Ocello (2025, equation (30))). Still, such conditions on π_D in existing Wasserstein-2 convergence analysis do not fully reflect the complexity of real-world data, which often exhibit non-smooth or non-log-concave distributions. Therefore, the aim of this work is to address the following fundamental question:

Can Score-based Generative Models be guaranteed to converge in Wasserstein-2 distance when the data distribution is only semiconvex and the potential admits discontinuous gradients?

We provide a positive answer to this question by combining recent findings in non-smooth, non-log-concave sampling, with standard stochastic analysis tools, thereby presenting the first contributions in the Score-based generative modeling literature for non-smooth potentials. We establish explicit, non-asymptotic Wasserstein-2 convergence bounds for SGMs under semiconvexity assumptions on the data distribution, accommodating potentials with discontinuous gradients. This framework covers a variety of practically relevant distributions arising in Bayesian statistical methods, including symmetric modified half-normal distributions, Gaussian mixtures, double-well potentials, and elastic net potentials, all of which satisfy our relaxed assumptions.

In addition, our estimates are explicit and exhibit the best known optimal dependencies in terms of data dimension, i.e., $O(\sqrt{d})$ in Theorem 13, and rate of convergence, i.e., $O(\gamma)$ in Theorem 15. In contrast to prior works under the same metric Gentiloni-Silveri & Ocello (2025); Gao et al. (2025); Strasman et al. (2025); Tang & Zhao (2024), our estimates in Theorems 13 and Theorem 15 are derived without imposing any restrictions on the stepsize of the generative algorithm, making them more suitable to practical implementation. By circumventing the need for strict regularity conditions on the score function and allowing discontinuities in the gradients of the potentials, our work significantly expands the theoretical foundation of SGMs. This advancement not only bridges the gap between empirical success and theoretical guarantees but also opens new avenues for the application of diffusion models to data distributions with non-smooth potentials.

One source of error in the construction of the generative algorithm arises from replacing the initial condition of the backward process with the invariant measure of the forward process. To ensure this error remains small, the drift terms of both SDEs must satisfy, for instance, a monotonicity property with a time-dependent bound that meets an appropriate integrability condition (see, e.g., equation 19 and equation 23 below). To address this, we identify a time horizon for the generative algorithm that ensures the paths of the two backward processes become contractive. Notably, the integrability condition on the monotonicity bound depends only on the known constants in Assumption 2, making it significantly easier to verify in practice

compared to the analogous condition in Gentiloni-Silveri & Ocello (2025, Appendix C), which relies on weak convexity constants that are often difficult to estimate.

In conclusion, we present the first explicit, dimension- and parameter-dependent W_2 -convergence guarantees for Score-based Generative models operating on data distributions having potentials with discontinuous gradients. Our results mark an important step forward in the rigorous analysis of SGMs, providing both theoretical insights and practical tools for advancing generative modeling in challenging, non-smooth regimes.

Notation. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a fixed probability space. We denote by $\mathbb{E}[X]$ the expectation of a random variable X . For $1 \leq p < \infty$, L^p is used to denote the usual space of p -integrable real-valued random variables. The L^p -integrability of a random variable X is defined as $\mathbb{E}[|X|^p] < \infty$. Fix an integer $d \geq 1$. For an \mathbb{R}^d -valued random variable X , its law on $\mathcal{B}(\mathbb{R}^d)$, i.e. the Borel sigma-algebra of \mathbb{R}^d is denoted by $\mathcal{L}(X)$. Let $T > 0$ denote a time horizon. For a positive real number b , we denote its integer part by $\lfloor b \rfloor$. The Euclidean scalar product is denoted by $\langle \cdot, \cdot \rangle$, with $|\cdot|$ standing for the corresponding norm (where the dimension of the space may vary depending on the context). Let $f : \mathbb{R}^d \rightarrow \mathbb{R}$ be a continuously differentiable function. The gradient of f is denoted by ∇f . For any integer $q \geq 1$, let $\mathcal{P}(\mathbb{R}^q)$ be the set of probability measures on $\mathcal{B}(\mathbb{R}^q)$. For $\mu, \nu \in \mathcal{P}(\mathbb{R}^d)$, let $\mathcal{C}(\mu, \nu)$ denote the set of probability measures ζ on $\mathcal{B}(\mathbb{R}^{2d})$ such that its respective marginals are μ and ν . For any μ and $\nu \in \mathcal{P}(\mathbb{R}^d)$, the Wasserstein distance of order 2 is defined as

$$W_2(\mu, \nu) = \left(\inf_{\zeta \in \mathcal{C}(\mu, \nu)} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} |x - y|^2 d\zeta(x, y) \right)^{\frac{1}{2}}.$$

For any $x \in A \subseteq \mathbb{R}^d$ and any function $U : A \rightarrow \mathbb{R}$, the subdifferential $\partial U(x)$ of U at x is defined as

$$\partial U(x) = \left\{ p \in \mathbb{R}^d : \liminf_{y \rightarrow x} \frac{U(y) - U(x) - \langle p, y - x \rangle}{|y - x|} \geq 0 \right\}. \quad (1)$$

At the points where U is differentiable, it holds that $\partial U(x) = \{\nabla U(x)\}$. For the sake of presentation, an element of $\partial U(x)$ is denoted by $h(x)$ for any $x \in \mathbb{R}^d$.

2 Technical Background for OU-based SGMs

In this section, we briefly summarize the construction of score-based generative models (SGMs) via diffusion processes, as introduced by Song et al. (2021). The core idea behind SGMs is to employ an ergodic (forward) diffusion process that gradually transforms the unknown data distribution $\pi_D \in \mathcal{P}(\mathbb{R}^d)$ into a known prior distribution. A backward (in time) process is then learned to transform the prior back to the target distribution π_D by estimating the score function of the forward process. In our analysis, we consider the forward process $(X_t)_{t \in [0, T]}$ to be an Ornstein-Uhlenbeck (OU) process, consistent with the choice in the original paper Song et al. (2021)

$$dX_t = -X_t dt + \sqrt{2} dB_t, \quad X_0 \sim \pi_D, \quad (2)$$

where $(B_t)_{t \in [0, T]}$ is an d -dimensional Brownian motion and we assume that $\mathbb{E}[|X_0|^2] < \infty$. Under mild assumptions on the target data distribution π_D (Haussmann & Pardoux, 1986; Cattiaux et al., 2023), the backward process $(Y_t)_{t \in [0, T]} = (X_{T-t})_{t \in [0, T]}$ is given by

$$dY_t = (Y_t + 2\nabla \log p_{T-t}(Y_t)) dt + \sqrt{2} d\bar{B}_t, \quad Y_0 \sim \mathcal{L}(X_T), \quad (3)$$

where $\{p_t\}_{t \in [0, T]}$ is the family of densities of $\{\mathcal{L}(X_t)\}_{t \in [0, T]}$ with respect to the Lebesgue measure, \bar{B}_t is another Brownian motion independent of B_t in 2 defined on $(\Omega, \mathcal{F}, \mathbb{P})$. In practice, however, the initial distribution is taken to be the invariant measure of the forward process, which corresponds to the standard Gaussian distribution. As a result, the backward process in 3 becomes

$$d\tilde{Y}_t = (\tilde{Y}_t + 2\nabla \log p_{T-t}(\tilde{Y}_t)) dt + \sqrt{2} d\bar{B}_t, \quad \tilde{Y}_0 \sim \pi_\infty = \mathcal{N}(0, I_d). \quad (4)$$

Since the target distribution π_D is unknown, the score function $\nabla \log p_t$ in 3 cannot be computed exactly. To overcome this limitation, an estimator $s(\cdot, \theta^*, \cdot)$ is *learned* based on a family of functions $s : [0, T] \times \mathbb{R}^M \times \mathbb{R}^d \rightarrow$

\mathbb{R}^d parametrized in θ , aiming at approximating the score of the ergodic forward process 5 over a fixed time window $[0, T]$. In practice, s are neural networks and in particular cases, e.g., the motivating example in Bruno et al. (2025, Section 3.1), the functions s can be carefully designed. The optimal value θ^* of the parameter θ is determined by optimizing the following score-matching objective

$$\mathbb{R}^d \ni \theta \mapsto \mathbb{E} \left[\int_0^T |\nabla \log p_t(X_t) - s(t, \theta, X_t)|^2 dt \right]. \quad (5)$$

An explicit expression of the stochastic gradient of 5 derived via denoising score matching (Vincent, 2011) is provided in Bruno et al. (2025, equation (8), Section 2). Following Bruno et al. (2025, Section 2), we define an auxiliary process $(Y_t^{\text{aux}})_{t \in [0, T]}$ that incorporates the approximating function s , which depends on the (random) estimator of θ^* denoted by $\hat{\theta}$. For $t \in [0, T]$, this process is given by

$$dY_t^{\text{aux}} = (Y_t^{\text{aux}} + 2 s(T - t, \hat{\theta}, Y_t^{\text{aux}})) dt + \sqrt{2} d\bar{B}_t, \quad Y_0^{\text{aux}} \sim \pi_\infty = \mathcal{N}(0, I_d). \quad (6)$$

The auxiliary process 6 serves as a bridge between the backward process 4 and the numerical scheme 8, and it facilitates the analysis of the convergence of the diffusion model (see the upper bounds involving Y_t^{aux} in the proof of Theorem 13 in Appendix C for further details). We now introduce the numerical scheme. Let the step size $\gamma_k = \gamma \in (0, 1)$ for each $k = 0, \dots, K$, where $K \in \mathbb{N}$. The discrete process $(Y_k^{\text{EM}})_{k \in \{0, \dots, K+1\}}$ of the Euler–Maruyama approximation of 6 is given, for any $k \in \{0, \dots, K\}$, as follows

$$Y_{k+1}^{\text{EM}} = Y_k^{\text{EM}} + \gamma(Y_k^{\text{EM}} + 2 s(T - t_k, \hat{\theta}, Y_k^{\text{EM}})) + \sqrt{2\gamma} \bar{Z}_{k+1}, \quad Y_0^{\text{EM}} \sim \pi_\infty = \mathcal{N}(0, I_d), \quad (7)$$

where $\{\bar{Z}_k\}_{k \in \{0, \dots, K+1\}}$ is a sequence of independent d -dimensional Gaussian random variables with zero mean and identity covariance matrix. The continuous-time interpolation of 7, for $t \in [0, T]$, is given by

$$d\hat{Y}_t^{\text{EM}} = (\hat{Y}_{\lfloor t/\gamma \rfloor \gamma}^{\text{EM}} + 2 s(T - \lfloor t/\gamma \rfloor \gamma, \hat{\theta}, \hat{Y}_{\lfloor t/\gamma \rfloor \gamma}^{\text{EM}})) dt + \sqrt{2} d\bar{B}_t, \quad \hat{Y}_0^{\text{EM}} \sim \pi_\infty = \mathcal{N}(0, I_d), \quad (8)$$

where $\mathcal{L}(\hat{Y}_k^{\text{EM}}) = \mathcal{L}(Y_k^{\text{EM}})$ at grid points for each $k \in \{0, \dots, K+1\}$.

3 Wasserstein Convergence Analysis for SGMs

In this section, we provide the full non-asymptotic estimates in Wasserstein distance of order two between the target data distribution π_D and the generative distribution of the diffusion model under the assumptions stated below. As discussed in Bruno et al. (2025, Section 2 and Appendix A), it may be necessary to restrict $t \in [\epsilon, T]$ for $\epsilon \in (0, 1)$ in 5 to account for numerical instabilities that can arise during training and sampling near $t = 0$ as also observed in practice in Song et al. (2021, Appendix C), and for the possibility that the integral of the score function in 5 may diverge when $t = 0$. Therefore, we truncate the integration in the backward diffusion at $T - \epsilon$ and consider the process $(Y_t)_{t \in [0, T-\epsilon]}$.

3.1 Assumptions

We begin by stating the main assumptions of our setting. The optimization problem in 5 can be solved using algorithms such as stochastic gradient descent (Jentzen et al., 2021), ADAM (Kingma & Ba, 2015), Stochastic Gradient Langevin Dynamics (Bruno et al., 2025, Section 3.1), and TheoPouLa (Lim & Sabanis, 2024), provided they satisfy the following assumption.

Assumption 1. *Let θ^* be a minimiser¹ of 5 and let $\hat{\theta}$ be the (random) estimator of θ^* obtained through some approximation procedure such that $\mathbb{E}[|\hat{\theta}|^2] < \infty$. There exists $\tilde{\varepsilon}_{AL} > 0$ such that*

$$\mathbb{E}[|\hat{\theta} - \theta^*|^2] < \tilde{\varepsilon}_{AL}.$$

Remark 1. *As a consequence of Assumption 1, one obtains $\mathbb{E}[|\hat{\theta}|^2] < 2\tilde{\varepsilon}_{AL} + 2|\theta^*|^2$.*

¹The score-matching optimization problem 5 is not necessarily (strongly) convex.

Recall that for any $x \in \mathbb{R}^d$, $h(x)$ denotes an element of the subdifferential $\partial U(x)$ defined in 1.

Assumption 2. The data distribution π_D has a finite second moment and it is absolutely continuous with respect to the Lebesgue measure with $\pi_D(dx) = \exp(-U(x)) dx$ for some $U : \mathbb{R}^d \rightarrow \mathbb{R}$. Moreover,

(i) The potential U is continuous and its gradient exists almost everywhere.

(ii) The potential U is K -semiconvex. That is, there exists $K, R \geq 0$, such that for all $x, \bar{x} \in \mathbb{R}^d$,

$$\langle h(x) - h(\bar{x}), x - \bar{x} \rangle \geq -K|x - \bar{x}|^2, \quad \text{when } |x - \bar{x}| < R,$$

or equivalently $U + \frac{K}{2}|\cdot|^2$ is convex.

(iii) The potential U is μ -strongly convex at infinity. That is, there exists $\mu > 0$ and $R \geq 0$, such that for all $x, \bar{x} \in \mathbb{R}^d$,

$$\langle h(x) - h(\bar{x}), x - \bar{x} \rangle \geq \mu|x - \bar{x}|^2, \quad \text{when } |x - \bar{x}| \geq R. \quad (9)$$

Remark 2. As a consequence of Proposition 17, due to Conforti et al. (2025, Proposition 3.1), and Assumption 2-(i), $\nabla \log p_t(x)$ is continuous for $t \in (0, T]$ and $x \in \mathbb{R}^d$. Moreover, Assumption 2 implies that the processes in 3 and 4 have a unique strong solution.

Next, we consider the following assumption on the approximating function s .

Assumption 3.a. The function $s : [0, T] \times \mathbb{R}^M \times \mathbb{R}^d \rightarrow \mathbb{R}^d$ is continuously differentiable in $x \in \mathbb{R}^d$. Let $D_1 : \mathbb{R}^M \times \mathbb{R}^M \rightarrow \mathbb{R}_+$, $D_2 : [0, T] \times [0, T] \rightarrow \mathbb{R}_+$ and $D_3 : [0, T] \times [0, T] \rightarrow \mathbb{R}_+$ be such that $\int_\epsilon^T \int_\epsilon^T D_2(t, \bar{t}) dt d\bar{t} < \infty$ and $\int_\epsilon^T \int_\epsilon^T D_3(t, \bar{t}) dt d\bar{t} < \infty$. For $\alpha \in [\frac{1}{2}, 1]$ and for all $t, \bar{t} \in [0, T]$, $x, \bar{x} \in \mathbb{R}^d$, and $\theta, \bar{\theta} \in \mathbb{R}^M$, we have that

$$|s(t, \theta, x) - s(\bar{t}, \bar{\theta}, \bar{x})| \leq D_1(\theta, \bar{\theta})|t - \bar{t}|^\alpha + D_2(t, \bar{t})|\theta - \bar{\theta}| + D_3(t, \bar{t})|x - \bar{x}|,$$

where D_1 , D_2 and D_3 have the following growth in each variable: i.e., there exist K_1 , K_2 , and $K_3 > 0$ such that for each $t, \bar{t} \in [0, T]$ and $\theta, \bar{\theta} \in \mathbb{R}^M$,

$$\begin{aligned} |D_1(\theta, \bar{\theta})| &\leq K_1(1 + |\theta| + |\bar{\theta}|), & |D_2(t, \bar{t})| &\leq K_2(1 + |t|^\alpha + |\bar{t}|^\alpha), \\ |D_3(t, \bar{t})| &\leq K_3(1 + |t|^\alpha + |\bar{t}|^\alpha). \end{aligned}$$

Remark 3. Assumption 3.a implies that the process in 6, 7, and 8 have a unique strong solution. For a discussion on the practical justification of this assumption in the context of neural network-based approximations, we refer the reader to Bruno et al. (2025, Remark 6).

Remark 4. Let $K_{Total} := K_1 + K_2 + K_3 + |s(0, 0, 0)| > 0$. Using Assumption 3.a, one obtains

$$|s(t, \theta, x)| \leq K_{Total}(1 + |t|^\alpha)(1 + |\theta| + |x|).$$

The proof of Remark 4 can be found, e.g., in Bruno et al. (2025, Appendix D.3). By imposing an additional condition on the gradient of s in Assumption 3.a, we obtain the optimal convergence rate established in Theorem 15 below.

Assumption 3.b. Let s be as in Assumption 3.a and there exists $K_4 > 0$ such that, for all $x, \bar{x} \in \mathbb{R}^d$ and for any $k = 1, \dots, d$,

$$|\nabla_x s^{(k)}(t, \theta, x) - \nabla_{\bar{x}} s^{(k)}(t, \theta, \bar{x})| \leq K_4(1 + 2|t|^\alpha)|x - \bar{x}|.$$

For the following assumption on the score approximation, we let $\hat{\theta}$ be as in Assumption 1 and we let $(Y_t^{\text{aux}})_{t \in [0, T]}$ be the auxiliary process defined in 6.

Assumption 4. There exists $\varepsilon_{SN} > 0$ such that

$$\mathbb{E} \int_0^{T-\epsilon} |\nabla \log p_{T-r}(Y_r^{\text{aux}}) - s(T-r, \hat{\theta}, Y_r^{\text{aux}})|^2 dr < \varepsilon_{SN}. \quad (10)$$

Remark 5. Assumption 4 is now a standard assumption considered in the literature, see, e.g., Gao et al. (2025); Bruno et al. (2025); Strasman et al. (2025); Gentiloni-Silveri & Ocello (2025), and its theoretical and practical soundness is discussed, e.g., in Bruno et al. (2025, Remark 7, 8, and 9).

3.2 Assumption 2 and Weak Convexity of the Data Distribution

We show that Assumption 2-(ii) and Assumption 2-(iii) are related to the notion of weak convexity in the sense made precise in Proposition 8 below. We start by introducing the definition of weak convexity for subgradients.

Definition 6. The potential $U : \mathbb{R}^d \rightarrow \mathbb{R}$ is weakly convex if its weak convexity profile $\kappa_U : [0, \infty) \rightarrow \mathbb{R}$ defined as

$$\kappa_U(r) = \inf_{x, \bar{x} \in \mathbb{R}^M : |x - \bar{x}| = r} \left\{ \frac{\langle \partial U(x) - \partial U(\bar{x}), x - \bar{x} \rangle}{|x - \bar{x}|^2} \right\} \quad (11)$$

satisfies

$$\kappa_U(r) \geq \beta - r^{-1} f_L(r), \quad \text{for all } r > 0, \quad (12)$$

for some constants $\beta, L > 0$, where the function $f_L : [0, \infty] \rightarrow [0, \infty]$ is defined as

$$f_L(r) = 2L^{1/2} \tanh((rL^{1/2})/2). \quad (13)$$

We modify Conforti et al. (2023, Lemma 5.9) to our setting, namely when $\beta > 0^2$ to have an explicit expression of the weak convexity constant at each $t \in [0, T]$.

Lemma 7. (Conforti et al., 2023, Modification of Lemma 5.9) Assume that U is weakly convex as in Definition 6 and fix $t \in [0, T]$. Then, the function $x \mapsto -\log p_t(x)$ is weakly convex with weak convexity profile $\kappa_{-\log p_t(x)}$ satisfying

$$\kappa_{-\log p_t}(r) \geq \frac{\beta}{\beta + (1 - \beta)e^{-2t}} - \frac{e^{-t}}{\beta + (1 - \beta)e^{-2t}} \frac{1}{r} f_L\left(\frac{e^{-t}}{\beta + (1 - \beta)e^{-2t}} r\right).$$

In particular, the score function satisfies

$$\langle \nabla \log p_t(x) - \nabla \log p_t(\bar{x}), x - \bar{x} \rangle \leq -\widehat{C}_t |x - \bar{x}|^2, \quad \text{for } x, \bar{x} \in \mathbb{R}^d, \quad (14)$$

with

$$\widehat{C}_t = \frac{\beta}{\beta + (1 - \beta)e^{-2t}} - \frac{e^{-2t}}{(\beta + (1 - \beta)e^{-2t})^2} L. \quad (15)$$

An overview of the proof of Proposition 8 below can be found in Appendix B.

Proposition 8. Let the data distribution π_D be in Assumption 2 and let f_L be as in 13. Then

$$\kappa_U(r) \geq \mu - r^{-1} f_L(r), \quad \text{for all } r > 0, \quad (16)$$

where $\mu > 0$ is the strong convexity at infinity constant from Assumption 2-(iii). Conversely, if U is weakly convex as in Definition 6 with lower bound 16 for some known constants μ and $L > 0$, then

1. The potential U is $\tilde{\mu}$ -strongly convex at infinity with $\tilde{\mu} := \mu - R^{-1} f_L(R) > 0$, such that for all $x, \bar{x} \in \mathbb{R}^d$, we have

$$\langle h(x) - h(\bar{x}), x - \bar{x} \rangle \geq \tilde{\mu} |x - \bar{x}|^2, \quad \text{when } |x - \bar{x}| \geq R, \quad (17)$$

which holds for all $R > 0$ when $\mu > L$ and for $R \geq R_0 = \frac{2z_0}{L^{1/2}}$ with z_0 being the solution of 43 when $\mu \leq L$.

2. The potential U is K -semiconvex, such that there exists $K, R \geq 0$ for all $x, \bar{x} \in \mathbb{R}^d$,

$$\langle h(x) - h(\bar{x}), x - \bar{x} \rangle \geq -K |x - \bar{x}|^2, \quad \text{when } |x - \bar{x}| \leq R. \quad (18)$$

As a consequence of Proposition 8 and Lemma 7, one obtains the explicit form of \widehat{C}_t in 14 in our setting, which is given in the following corollary.

²See Gentiloni-Silveri & Ocello (2025, Lemma B.4) for a similar statement.

Corollary 9. *Let U be K -semiconvex as in Assumption 2-(ii) and be μ -strongly convex at infinity as in Assumption 2-(iii) and fix $t \in [0, T]$. Then*

$$\langle \nabla \log p_t(x) - \nabla \log p_t(\bar{x}), x - \bar{x} \rangle \leq -\beta_t^{OS} |x - \bar{x}|^2, \quad \text{for } x, \bar{x} \in \mathbb{R}^d, \quad (19)$$

where

$$\beta_t^{OS} = \frac{\mu}{\mu + (1 - \mu)e^{-2t}} - \frac{e^{-2t}}{(\mu + (1 - \mu)e^{-2t})^2} L, \quad (20)$$

for some $L > 0$ satisfying 16.

Remark 10. *By Corollary 9 and the proof of Proposition 8, we have*

$$\lim_{t \rightarrow 0} \beta_t^{OS} = \mu - L < -K. \quad (21)$$

We emphasize that the gap between the limit on the left-hand side of 21 and the semiconvexity constant K is due to the particular choice of f_L in 13 in Proposition 8. This gap may vanish for different functions $f \in \tilde{\mathcal{F}}$, where

$$\tilde{\mathcal{F}} := \left\{ f \in C^2((0, \infty), \mathbb{R}_+) : r \mapsto r^{1/2} f(r^{1/2}), \text{ non-decreasing, concave, bounded such that } \lim_{r \downarrow 0} r f(r) = 0, f' \geq 0, 2f'' + f f' \leq 0 \right\}.$$

For this reason, we use the constant $K + \mu$ as a proxy of the constant L and replace 20 with the following monotonicity bound

$$\beta_t^{OS, K, \mu} = \frac{\mu}{\mu + (1 - \mu)e^{-2t}} - \frac{e^{-2t}}{(\mu + (1 - \mu)e^{-2t})^2} (K + \mu). \quad (22)$$

Moreover, it holds that

$$\lim_{t \rightarrow 0} \beta_t^{OS, K, \mu} = -K,$$

and

$$\lim_{t \rightarrow \infty} \beta_t^{OS} = \lim_{t \rightarrow \infty} \beta_t^{OS, K, \mu} = 1,$$

which is consistent with $\pi_\infty \sim \mathcal{N}(0, I_d)$, the invariant distribution of the OU process.

Using the explicit expression of 22, we are able to find a time for which the integral of the monotonicity bound³ $\beta_t^{OS, K, \mu}$ is positive. The proof of the following result is postponed to Appendix B.

Proposition 11. *Let $\mu > 0$ and $K \geq 0$. The time integral of $\beta_t^{OS, K, \mu}$ from Remark 10 is*

$$\begin{aligned} B(t, 0, \mu, K) &= \int_0^t \left(\frac{\mu}{\mu + (1 - \mu)e^{-2s}} - \frac{e^{-2s}}{(\mu + (1 - \mu)e^{-2s})^2} (K + \mu) \right) ds \\ &= \frac{1}{2} \left[\log(\mu(e^{2t} - 1) + 1) + \left(\frac{K}{\mu} + 1 \right) \left(\frac{1}{\mu(e^{2t} - 1) + 1} - 1 \right) \right] > 0, \end{aligned} \quad (23)$$

when $t > t^* > \ln\left(\sqrt{1 + \frac{K}{\mu^2}}\right)$ with $t^* := \inf\{t > 0 : B(t, 0, \mu, K) > 0\}$.

Remark 12. *If we consider the case when $K = 0$ in Assumption 2-(ii), then 23 is satisfied for all $t > 0$.*

3.3 Main Results - Optimal Data Dimensional Dependence and Rate of Convergence

The main results are stated as follows. An overview of their proofs can be found in Appendix C.

³Note that $\beta_t^{OS, K, \mu}$ is a function of time.

Theorem 13. *Let Assumptions 1, 2, 3.a and 4 hold. Then, there exist constants C_1, C_2, C_3 and $C_4 > 0$ such that for any $T > 0$ and $\gamma, \epsilon \in (0, 1)$,*

$$W_2(\mathcal{L}(Y_K^{EM}), \pi_D) \leq C_1\sqrt{\epsilon} + C_2e^{-2\int_{\epsilon}^T \beta_t^{OS,K,\mu} dt - \epsilon} + C_3(T, \epsilon)\sqrt{\varepsilon_{SN}} + C_4(T, \epsilon)\gamma^{1/2}, \quad (24)$$

where C_1, C_2, C_3 and C_4 are given explicitly in Table 2 (Appendix E), $\beta_t^{OS,K,\mu}$ is defined in 22, and its integral is computed in Proposition 11. In addition, the result in 24 implies that for any $\delta > 0$, if we choose $0 < \epsilon < \epsilon_\delta$, $T > T_\delta$, $0 < \varepsilon_{SN} < \varepsilon_{SN,\delta}$ and $0 < \gamma < \gamma_\delta$ with $\epsilon_\delta, T_\delta, \varepsilon_{SN,\delta}$, and γ_δ given in Table 2, then

$$W_2(\mathcal{L}(Y_K^{EM}), \pi_D) < \delta.$$

Remark 14. *The constant $C_4(T, \epsilon)$ in the error bound in 24 contains the optimal dependence of the data dimension, i.e. $O(\sqrt{d})$, which has been found under the more strict assumption of strong-log concavity of π_D in Bruno et al. (2025, Theorem 1 and Remark 12). However, the optimal dependence of the dimension is achieved at the expenses of a worst rate of convergence of order $1/2$.*

The optimal rate of convergence of order $\alpha \in [\frac{1}{2}, 1]$ for the Euler or Milstein scheme of SDEs with constant diffusion coefficients can be attained in Theorem 13 provided that $\mathbb{E}[|\hat{\theta}|^4] < \infty$ and that Assumption 3.a is replaced by Assumption 3.b, as stated in Theorem 15 below.

Theorem 15. *Let Assumptions 1, 2, 3.b and 4 hold, and assume that $\mathbb{E}[|\hat{\theta}|^4] < \infty$. Then, there exist constants C_1, C_2, C_3 and $\tilde{C}_4 > 0$ such that for any $T > 0$ and $\gamma, \epsilon \in (0, 1)$,*

$$W_2(\mathcal{L}(Y_K^{EM}), \pi_D) \leq C_1\sqrt{\epsilon} + C_2e^{-2\int_{\epsilon}^T \beta_t^{OS,K,\mu} dt - \epsilon} + C_3(T, \epsilon)\sqrt{\varepsilon_{SN}} + \tilde{C}_4(T, \epsilon)\gamma^\alpha, \quad (25)$$

where C_1, C_2, C_3 and \tilde{C}_4 are given explicitly in Table 2 (Appendix E), $\beta_t^{OS,K,\mu}$ is defined in 22, and its integral is computed in Proposition 11. In addition, the result in 25 implies that for any $\delta > 0$, if we choose $0 < \epsilon < \epsilon_\delta$, $T > T_\delta$, $0 < \varepsilon_{SN} < \varepsilon_{SN,\delta}$ and $0 < \gamma < \tilde{\gamma}_\delta$ with $\epsilon_\delta, T_\delta, \varepsilon_{SN,\delta}$, and $\tilde{\gamma}_\delta$ given in Table 2, then

$$W_2(\mathcal{L}(Y_K^{EM}), \pi_D) < \delta. \quad (26)$$

Remark 16. *The explicit expression of \tilde{C}_4 in Table 2 (Appendix E) exhibits an $O(d)$ dependence of the data dimension, resulting from numerical techniques introduced in Kumar & Sabanis (2019) and employed in the proof of Theorem 15 to achieve the optimal convergence rate of order $\alpha \in [\frac{1}{2}, 1]$.*

3.4 Examples of potentials satisfying by Assumption 2

We present several examples to demonstrate the wide applicability of our Assumption 2 to a broad class of data distributions, some of which are not covered by previous results in Wasserstein distance of order two (Gentiloni-Silveri & Ocello, 2025; Strasman et al., 2025; Gao et al., 2025; Bruno et al., 2025; Tang & Zhao, 2024; Yu & Yu, 2025).

3.4.1 Symmetric modified half-normal distribution

We consider the case of a one-dimensional symmetric modified half-normal distribution

$$\pi_D(dx) = \frac{\sqrt{\xi} \exp(-\xi x^2 - |x|)}{\Psi\left(\frac{1}{2}, \frac{-1}{\sqrt{\xi}}\right)} dx, \quad x \in \mathbb{R}, \quad (27)$$

for some unknown $\xi > 0$ and normalizing constant

$$\Psi\left(\frac{1}{2}, \frac{-1}{\sqrt{\xi}}\right) := \sum_{n=0}^{\infty} \frac{\Gamma\left(\frac{1}{2} + \frac{n}{2}\right)}{\Gamma(n)} \frac{(-1)^n \xi^{-n/2}}{n!},$$

where $\Gamma(n)$ is the Gamma function. We refer the reader to Appendix D for additional details about the derivation of 27. As highlighted in Sun et al. (2023, Section 2), the modified half-normal distribution

appears in several Bayesian statistical methods as a posterior distribution to sample from in Bayesian Binary regression, analysis of directional data, and Bayesian graphical models.

Assumption 2-(i) is satisfied for $U(x) = \xi x^2 + |x|$. In addition, we have, for all $x, \bar{x} \in \mathbb{R}$

$$\begin{aligned} \langle h(x) - h(\bar{x}), x - \bar{x} \rangle &= 2 \left(\xi |x - \bar{x}|^2 + (x - \bar{x}) \mathbb{1}_{x>0, \bar{x}<0} - (x - \bar{x}) \mathbb{1}_{x<0, \bar{x}>0} \right) \\ &\geq 2\xi |x - \bar{x}|^2, \end{aligned} \quad (28)$$

which shows that Assumption 2-(ii) is verified for any $K \geq 0$, and Assumption 2-(iii) is verified for $\mu = 2\xi$. Therefore, we can conclude that 27 satisfies Assumption 2.

3.4.2 Multidimensional Gaussian mixture distribution

We consider a multidimensional Gaussian mixture data distribution with unknown mean and variance, i.e.,

$$\pi_D(dx) = \sum_{j=1}^J \tilde{\xi}_j \frac{1}{(2\pi\sigma_j^2)^{d/2}} \exp\left(-\frac{|x - \eta_j|^2}{2\sigma_j^2}\right) dx, \quad x \in \mathbb{R}^d, \quad (29)$$

with $\sigma_j > 0$, $\eta_j \in \mathbb{R}^d$, and $\tilde{\xi}_j \in [0, 1]$ for $j \in \{1, \dots, J\}$ such that $\sum_{j=1}^J \tilde{\xi}_j = 1$. The authors in Gentiloni-Silveri & Ocello (2025, Appendix A) show that the score function of 29 is Lipschitz continuous and $-\log \pi_D$ is weakly convex. Therefore, Assumption 2 is satisfied. In addition, the distribution 29 covers also case of the double-well potential:

$$U(x) = x^4 - |x|^2, \quad x \in \mathbb{R}^d, \quad (30)$$

which is 2-semiconvex and strongly convex at infinity.

3.4.3 Multi-dimensional Potentials

Similarly as in Section 3.4.1, one can prove that the elastic net potential:

$$U(x) = |x|^2 + \sum_{i=1}^d |x_i|, \quad x \in \mathbb{R}^d, \quad (31)$$

satisfies Assumption 2. Moreover, the following potential

$$U(x) = \max \{|x|, |x|^2\}, \quad x \in \mathbb{R}^d, \quad (32)$$

verifies Assumption 2 with $K = 0$, $R = 1$, and $\mu = 2$ as well as the following non-convex potential presented in Johnston et al. (2025, Example 4.2):

$$U(x) = \max \{|x|, |x|^2\} - \frac{1}{2}|x|^2, \quad x \in \mathbb{R}^d. \quad (33)$$

4 Related Work and Comparison

In recent years, there has been a rapidly expanding body of research on the convergence theory of Score-based Generative Models. Existing works for convergence bounds can be divided into two main approaches, depending on the divergence or distance used.

The first approach focuses on α -divergences, particularly the Kullback–Leibler (KL) divergence and Total Variation (TV) distance (e.g., Benton et al. (2024); Conforti et al. (2025); Yang & Wibisono (2023); Li & Cai (2024); Block et al. (2020); De Bortoli et al. (2021); Lee et al. (2022); Li et al. (2024); Lee et al. (2023); Chen et al. (2023a;b); Oko et al. (2023); Liang et al. (2025); Yang & Wibisono (2022)), which are the vast majority of the results available in the literature. Crucially, bounds on KL divergence imply bounds on TV distance via Pinsker’s inequality, strengthening their wide applicability. We provide a brief and selective overview of some of the findings following this first approach. The results in TV distance in Lee et al. (2022)

and in KL divergence Yang & Wibisono (2023) established convergence bounds characterized by polynomial complexity under the assumption that the data distribution satisfies a logarithmic Sobolev inequality and that the score function is Lipschitz continuous. By replacing the requirement that the data distribution satisfies a functional inequality with the assumption that π_D has finite KL divergence with respect to the standard Gaussian and by assuming that the score function for the forward process is Lipschitz, the authors in Chen et al. (2023b) managed to derive bounds in TV distance which scale polynomially in all the problem parameters. By requiring only the Lipschitzness of the score at the initial time rather than along the full trajectory, the authors in Chen et al. (2023a, Theorem 2.5) managed to establish, using an exponentially decreasing then linear step size, convergence bounds in KL divergence with quadratic dimensional dependence and logarithmic complexity in the Lipschitz constant. Later, Benton et al. (2024) provided KL convergence bounds that are linear in the data dimension, up to logarithmic factors, by assuming finite second moments of the data distribution and employing early stopping. However, both the results of Chen et al. (2023a, Theorem 2.5) and Benton et al. (2024, Theorem 1 and Corollary 1) still require the uniqueness of solutions for the backward SDE 3, and therefore additional assumptions on the score function are needed. For further discussion on this point, we refer the reader to Bruno et al. (2025, Section 4.2). Assuming finite second moments and using an exponential integrator (EI) scheme with both constant and exponentially decaying step sizes, the authors in Conforti et al. (2025, Corollary 2.4) derive a KL divergence bound with early stopping, which scales linearly in the data dimension up to logarithmic factors. Bounds in KL without early stopping have been derived in Conforti et al. (2025) for data distributions with finite Fisher information with respect to the standard Gaussian distribution. We note that this condition on π_D stated in Conforti et al. (2025, Assumption H2) still requires that the potential $U \in C^1(\mathbb{R}^d)$. The KL bounds provided in Conforti et al. (2025, Theorem 2.1 and 2.2) scale linearly in the Fisher information when an EI discretization scheme with constant step size is used, and logarithmically in the Fisher information when an exponential-then-constant step size Conforti et al. (2025, Theorem 2.3) is employed.

The second approach focuses on convergence bounds in Wasserstein distance, a metric which is often considered more practical and informative for estimation tasks. We can relate results following this approach with the results of the first approach only when π_D is a strongly log-concave distribution. In this case, W_2 -bounds in terms of KL divergence follow from an extension of Talagrand’s inequality (Gozlan & Léonard, 2010, Corollary 7.2). However, for two general data distributions, there is no known relationship between their KL divergence and their W_2 . Therefore, we cannot compare our findings in Theorem 13 and Theorem 15 with the results derived following the first approach. One line of work within the second approach assumes (at least) strong log-concavity of the data distribution (Strasman et al., 2025; Gao et al., 2025; Bruno et al., 2025; Tang & Zhao, 2024; Yu & Yu, 2025). Under this (strict) assumption, Bruno et al. (2025, Remark 12) achieved optimal data dimensional dependence, i.e., reaching $O(\sqrt{d})$. The recent bound in Gentiloni-Silveri & Ocello (2025, Theorem D.1) scales linearly in the data dimension while relaxing the strong log-concavity assumption on π_D to weakly log-concavity, but still requiring that the potential $\nabla^2 U$ exists (see, e.g., Gentiloni-Silveri & Ocello (2025, Proof of Proposition B.1 and B.2)). Our Assumption 2 is much weaker than this requirement and it allows to consider the case of potentials with discontinuous gradients covering a wider range of distributions as outlined in Section 3.4. Another line of work following this approach focuses on specific structural assumptions of the data distribution. For instance, convergence bounds in Wasserstein distance of order one with exponential dependence on the problem parameters have been obtained in Bortoli (2022) under the so-called manifold hypothesis, namely assuming that the target distribution is supported on a lower-dimensional manifold or is given by some empirical distribution. Under the same metric, the authors in Mimikos-Stamatopoulos et al. (2024) provide a convergence analysis when the data distribution is defined on a torus. We summarize in Table 1 and the best results obtained in W_2 , i.e., Bruno et al. (2025); Gentiloni-Silveri & Ocello (2025) and compare with our best result, which scale polynomially in the data dimension, i.e. $O(\sqrt{d})$ in Theorem 13.

We close this section by briefly commenting on the choice of deriving our results in Wasserstein distance of order two. Beyond its theoretical relevance, this choice is motivated by practical considerations in generative modeling. First, the Wasserstein distance is often regarded as a more informative and robust metric for estimation tasks. Second, a widely used performance metric for evaluating the quality of images produced by generative models is the Fréchet Inception Distance (FID) Heusel et al. (2017), which measures the Fréchet distance between the distributions of generated and real samples, assuming Gaussian distributions.

In particular, this Fréchet distance is equivalent to the Wasserstein-2 distance. Thus, providing convergence results under the Wasserstein-2 metric enhances the practical relevance of our theoretical findings.

Table 1: Summary of previous bounds for $W_2(\mathcal{L}(\hat{Y}_K^{\text{EM}}, \pi_D)$ and our result in Theorem 13. All the bounds assume that $\pi_D(dx) \propto e^{-U(x)}dx$ has finite second moments.

Assumption on π_D	Error bound	Reference
U strongly convex, $\nabla \log p_t(0) \in L^2([\epsilon, T])$, and Assumption 4	$O(\sqrt{d})\sqrt{\epsilon} + O(\sqrt{d})e^{-2\hat{L}_{\text{MO}}(T-\epsilon)-\epsilon} + O(e^{(1+\zeta-2\hat{L}_{\text{MO}})(T-\epsilon)})\sqrt{\epsilon_{\text{SN}}} + O(\sqrt{d}e^{T^{2\alpha+1}}T^{2\alpha+1}\tilde{\epsilon}_{\text{AL}}^{1/2})\gamma^{1/2}$, with $\hat{L}_{\text{MO}} > 0$ lower bound of the strongly convex constant of U , see e.g., Bruno et al. (2025, Remark 4).	(Bruno et al., 2025, Remark 12)
$U \in C^2(\mathbb{R}^d)$, weakly convex, and Assumption 4	$e^{(2L_U+5)\eta(\beta, L, \gamma)}[e^{-T}W_2(\pi_D, \pi_\infty) + 4\epsilon_{\text{SN}}(T - \eta(\beta, L, 0)) + \sqrt{2\gamma}(4L_U d + 6d + \sqrt{d + \mathbb{E}[X_0 ^2]})(T - \eta(\beta, L, 0))]$, with $L_U \geq 0$ one-sided Lipschitz constant for ∇U , see e.g., Gentiloni-Silveri & Ocello (2025, Assumption H1), $\eta(\beta, L, \gamma)$ defined in (Gentiloni-Silveri & Ocello, 2025, equation (29)), and $\gamma < 2/(2L_U + 5)^2$.	Gentiloni-Silveri & Ocello (2025, Theorem D.1)
Assumption 2 and Assumption 4	$O(\sqrt{d})\sqrt{\epsilon} + O(\sqrt{d})e^{-2\int_\epsilon^T \beta_t^{\text{OS}, K, \mu} dt - \epsilon} + O(e^{(1+\zeta)(T-\epsilon)-2\int_\epsilon^T \beta_t^{\text{OS}, K, \mu} dt})\sqrt{\epsilon_{\text{SN}}} + O(\sqrt{d}e^{T^{2\alpha+1}}T^{3\alpha+1}\tilde{\epsilon}_{\text{AL}}^{1/2})\gamma^{1/2}$.	Theorem 13

Appendix

A Regularity of the Score Function

We recall the following result to justify the smoothness of the map

$$(0, T] \times \mathbb{R}^d \ni (t, x) \mapsto p_t(x) \in \mathbb{R}_+, \quad (34)$$

where p_t density of the forward process defined in Section 2.

Proposition 17. (*Conforti et al., 2025, Proposition 3.1*) *Let π_D be absolutely continuous with respect to the Lebesgue measure, and denote its density by p_0 . The map defined in 34 is positive and solution of the following Fokker–Planck equation on $(0, T] \times \mathbb{R}^d$:*

$$\partial_t p_t(x) - \operatorname{div}(x p_t) - \Delta p_t(x) = 0, \quad \text{for } (t, x) \in (0, T] \times \mathbb{R}^d.$$

Moreover, it belongs to $C^{1,2}((0, T] \times \mathbb{R}^d)$; i.e. for any $t \in (0, T)$, $x \mapsto p_t(x)$ is twice continuously differentiable, and for any $x \in \mathbb{R}^d$, $t \mapsto p_t(x)$ is continuously differentiable on $(0, T]$.

B Further Details on Assumption 2 and Weak Convexity of the Data Distribution

We provide the proofs of Section 3.2.

Proof of Proposition 8. We begin by considering that π_D satisfies Assumption 2. Recall that f_L is defined as in 13. Note that $r \mapsto r^{-1}f_L(r)$ is non-increasing on $(0, \infty)$ and $f'_L(0) = L > r^{-1}f_L(r)$ for $r \in (0, R]$. We look for $L > 0$ satisfying

$$\inf_{r \in (0, R]} r^{-1}f_L(r) = R^{-1}f_L(R) = 2R^{-1}L^{1/2} \tanh((RL^{1/2})/2) = K + \mu. \quad (35)$$

Equivalently, we look for $x = L^{1/2}R/2 > 0$ such that

$$x \tanh(x) = \frac{K + \mu}{4}R^2, \quad \text{subject to } x > \frac{\sqrt{K + \mu}}{2}R, \quad (36)$$

so as $L > K + \mu$. Note that $\tanh(x) \leq x$ for all $x \geq 0$. Therefore, if we choose $x = \frac{\sqrt{K + \mu}}{2}R$, then

$$\frac{\sqrt{K + \mu}}{2}R \tanh\left(\frac{\sqrt{K + \mu}}{2}R\right) \leq \frac{K + \mu}{4}R^2. \quad (37)$$

Using 37 and $\lim_{x \uparrow \infty} x \tanh(x) = \infty$, we deduce that there exists $x^* > 0$ such that

$$x^* \tanh(x^*) = \frac{K + \mu}{4}R^2, \quad (38)$$

with $x^* > \frac{\sqrt{K + \mu}}{2}R$, since $x \mapsto x \tanh(x)$ is non-decreasing on $(0, \infty)$. By Assumption 2 and 35, we have

$$\begin{aligned} k_U(r) &\geq \mu - (K + \mu) \\ &\geq \mu - r^{-1}f_L(r), \quad \text{for } r \leq R. \end{aligned} \quad (39)$$

Moreover,

$$\begin{aligned} k_U(r) &\geq \mu \\ &\geq \mu - r^{-1}f_L(r), \quad \text{for } r > R, \end{aligned}$$

where it is used that $r^{-1}f_L(r) > 0$ for all $r > 0$. This proves the first part of the statement in Proposition 8, i.e. the lower bound 16.

Conversely, assume that U is weakly convex as in Definition 6 with lower bound 16 for some known constants μ and $L > 0$. We look for R such that

$$\begin{aligned} \kappa_U(r) &\geq \mu - r^{-1}f_L(r) \\ &\geq \mu - R^{-1}f_L(R) \\ &> 0, \end{aligned} \quad \forall r > R, \quad (40)$$

where it is used that $r^{-1}f_L(r)$ is decreasing on $(0, \infty)$. Let $\tilde{\mu} := \mu - R^{-1}f_L(R)$, so 40 becomes $\kappa_U(r) \geq \tilde{\mu} > 0$, for all $r > R$. One notes that

$$\tilde{\mu} = \mu - L \frac{\tanh((RL^{1/2})/2)}{(RL^{1/2})/2} > 0. \quad (41)$$

If $\mu > L$, 41 is satisfied for all $R > 0$. If $\mu \leq L$, 41 holds for $R \geq R_0$, where R_0 is the unique solution to

$$\mu = \frac{2L^{1/2}}{R} \tanh\left(\frac{RL^{1/2}}{2}\right). \quad (42)$$

Let $z = \frac{RL^{1/2}}{2}$, then $R_0 = \frac{2z_0}{L^{1/2}}$, where z_0 solves

$$\frac{\tanh(z)}{z} = \frac{\mu}{L}. \quad (43)$$

Since $\frac{\tanh(z)}{z}$ monotonically decreases from 1 to 0 as z increases, a unique $z_0 > 0$ solving 43 exists for $\mu < L$. Therefore, 40 is satisfied for $R \geq R_0 = \frac{2z_0}{L^{1/2}}$. This proves that U is $\tilde{\mu}$ -strongly convex at infinity, and therefore 17. Using the assumption that U is weakly convex as in Definition 6, one obtains that

$$\begin{aligned} \kappa_U(r) &\geq \mu - r^{-1}f_L(r) \\ &\geq \mu - L, \quad \text{for } r \leq R. \end{aligned} \quad (44)$$

We distinguish two cases for the lower bound in 44. If $\mu > L$, then $\kappa_U(r) \geq -K$ for $r \leq R$ for all $R > 0$ and $K \geq 0$. If $\mu \leq L$, then, by setting $K = L - \mu$ in 43, we have $\kappa_U(r) \geq -K$ for $r \leq R$ for all $R > 0$. This proves that U is K -semiconvex, and therefore 18. This concludes the proof for the second part of the statement in Proposition 8. \square

Proof of Proposition 11. We look for t^* satisfying

$$B(t^*, 0, \mu, K) = \frac{1}{2} \left[\log(\mu(e^{2t^*} - 1) + 1) + \left(\frac{K}{\mu} + 1\right) \left(\frac{1}{\mu(e^{2t^*} - 1) + 1} - 1\right) \right] > 0. \quad (45)$$

Equivalently, we look for $x := e^{2t^*} - 1$ such that

$$g(\mu x + 1) = \log(\mu x + 1) - \left(\frac{K}{\mu} + 1\right) \frac{\mu x}{\mu x + 1} > 0. \quad (46)$$

Note that 46 is satisfied for all $x > 0$ when $K = 0$. In addition, we have

$$\begin{aligned} \lim_{x \rightarrow 0+} g(\mu x + 1) &= 0, \\ \lim_{x \rightarrow +\infty} g(\mu x + 1) &= \infty, \end{aligned} \quad (47)$$

and

$$\begin{aligned} \frac{d}{dx} g(\mu x + 1) &= \frac{\mu}{\mu x + 1} - \frac{K + \mu}{(\mu x + 1)^2} \geq 0 \quad \text{when } x \geq \frac{K}{\mu^2}, \\ \frac{d^2}{dx^2} g(\mu x + 1) &= -\frac{\mu^2}{(\mu x + 1)^2} + \frac{2(K + \mu)\mu}{(\mu x + 1)^3} \geq 0 \quad \text{when } x \leq \frac{2K}{\mu^2} + \frac{1}{\mu}. \end{aligned} \quad (48)$$

By 48, the function g in 46 has a minimum at $\frac{K}{\mu^2}$ and

$$g\left(\frac{K}{\mu} + 1\right) = \log\left(\frac{K}{\mu} + 1\right) - \frac{K}{\mu} < 0,$$

for all $K, \mu > 0$. By 47 and 48, there exists $x > \frac{K}{\mu^2}$ such that 46 is strictly positive. Therefore, there exists $t^* > \ln\left(\sqrt{1 + \frac{K}{\mu^2}}\right)$ such that 45 holds. \square

C Proof of the Main Results

In this section, we present the proofs of Theorem 13 and Theorem 15. We begin by recalling an upper bound on the moments of the process $(\hat{Y}_t^{\text{EM}})_{t \in [0, T]}$ defined in 8, along with an estimate for its one-step discretization error. These results will be instrumental in the subsequent proofs.

Lemma 18. (Bruno et al., 2025, Lemma 20) Let Assumptions 1 and 3.a hold, and suppose that $\mathbb{E}[|\hat{\theta}|^p] < \infty$ for any $p \in [2, 4]$. Then, for any $t \in [0, T - \epsilon]$,

$$\sup_{0 \leq s \leq t} \mathbb{E} \left[|\hat{Y}_s^{EM}|^p \right] \leq C_{EM,p}(t),$$

where

$$C_{EM,p}(t) := e^{t(3p-1-\frac{2}{p}+2^{2p-1}\mathbf{K}_{Total}^p(1+T^{\alpha p}))} \times \left(\mathbb{E} \left[|\hat{Y}_0^{EM}|^p \right] + 2^{3p-2}\mathbf{K}_{Total}^p t(1 + \mathbb{E}[|\hat{\theta}|^p])(1 + T^{\alpha p}) + \frac{2}{p}(pd + p(p-2))^{\frac{p}{2}} t \right),$$

and \mathbf{K}_{Total} is defined in Remark 4.

Lemma 19. (Bruno et al., 2025, Lemma 21) Let Assumptions 1 and 3.a hold, and suppose that $\mathbb{E}[|\hat{\theta}|^p] < \infty$ for any $p \in [2, 4]$. Then, for any $t \in [0, T - \epsilon]$,

$$\mathbb{E} \left[|\hat{Y}_t^{EM} - \hat{Y}_{\lfloor t/\gamma \rfloor \gamma}^{EM}|^p \right] \leq \gamma^{\frac{p}{2}} C_{EMose,p},$$

where

$$C_{EMose,p} := 2^{p-1}(C_{EM,p}(T) + \mathbf{K}_{Total}^p(1 + T^{\alpha p})(2^{3p-2}C_{EM,p}(T) + 2^{4p-3}(1 + \mathbb{E}[|\hat{\theta}|^p]))) + (dp(p-1))^{\frac{p}{2}},$$

$C_{EM,p}$ and \mathbf{K}_{Total} are defined in Lemma 18 and in Remark 4, respectively.

Proof of Theorem 13. We derive the non-asymptotic estimate for $W_2(\mathcal{L}(Y_K^{EM}), \pi_D)$ using the splitting

$$\begin{aligned} W_2(\mathcal{L}(Y_K^{EM}), \pi_D) &\leq W_2(\pi_D, \mathcal{L}(Y_{t_K})) + W_2(\mathcal{L}(Y_{t_K}), \mathcal{L}(\tilde{Y}_{t_K})) \\ &\quad + W_2(\mathcal{L}(\tilde{Y}_{t_K}), \mathcal{L}(Y_{t_K}^{aux})) + W_2(\mathcal{L}(Y_{t_K}^{aux}), \mathcal{L}(Y_K^{EM})). \end{aligned} \quad (49)$$

We provide upper bounds on the error made by the early stopping, i.e. $W_2(\pi_D, \mathcal{L}(Y_{t_K}))$, the error made by approximating the initial condition of the backward process $Y_0 \sim \mathcal{L}(X_T)$ with $\tilde{Y}_0 \sim \pi_\infty$, i.e. $W_2(\mathcal{L}(Y_{t_K}), \mathcal{L}(\tilde{Y}_{t_K}))$, the error made by approximating the score function with s , i.e. $W_2(\mathcal{L}(\tilde{Y}_{t_K}), \mathcal{L}(Y_{t_K}^{aux}))$, and the discretisation error, i.e. $W_2(\mathcal{L}(Y_{t_K}^{aux}), \mathcal{L}(Y_K^{EM}))$, separately.

Upper bound on $W_2(\pi_D, \mathcal{L}(Y_{t_K}))$. This bound can be established by following the same argument as in (Bruno et al., 2025, Proof of Theorem 10), which relies on the representation of the OU process

$$X_t \stackrel{\text{a.s.}}{=} m_t X_0 + \sigma_t Z_t, \quad m_t = e^{-t}, \quad \sigma_t^2 = 1 - e^{-2t}, \quad Z_t \sim \mathcal{N}(0, I_d), \quad (50)$$

where $\stackrel{\text{a.s.}}{=}$ denotes almost sure equality. Therefore, we have

$$W_2(\pi_D, \mathcal{L}(Y_{t_K})) \leq 2\sqrt{\epsilon}(\sqrt{\mathbb{E}[|X_0|^2]} + \sqrt{d}), \quad (51)$$

where $t_K = T - \epsilon$.

Upper bound on $W_2(\mathcal{L}(Y_{t_K}), \mathcal{L}(\tilde{Y}_{t_K}))$. Using Itô's formula, we have, for any $t \in [0, T - \epsilon]$,

$$\begin{aligned} d|Y_t - \tilde{Y}_t|^2 &= 2\langle Y_t - \tilde{Y}_t, Y_t + 2\nabla \log p_{T-t}(Y_t) - \tilde{Y}_t - 2\nabla \log p_{T-t}(\tilde{Y}_t) \rangle dt \\ &= 2|Y_t - \tilde{Y}_t|^2 dt + 4\langle Y_t - \tilde{Y}_t, \nabla \log p_{T-t}(Y_t) - \nabla \log p_{T-t}(\tilde{Y}_t) \rangle dt. \end{aligned} \quad (52)$$

By integrating and taking on both sides in 52, we have

$$\begin{aligned} \mathbb{E} \left[|Y_{t_K} - \tilde{Y}_{t_K}|^2 \right] &= \mathbb{E} \left[|Y_0 - \tilde{Y}_0|^2 \right] + \int_0^{t_K} 2\mathbb{E} \left[|Y_t - \tilde{Y}_t|^2 \right] dt \\ &\quad + \int_0^{t_K} 4\mathbb{E} \left[\langle Y_t - \tilde{Y}_t, \nabla \log p_{T-t}(Y_t) - \nabla \log p_{T-t}(\tilde{Y}_t) \rangle \right] dt. \end{aligned} \quad (53)$$

By integrating, taking expectations on both sides in 53, using Corollary 9, the representation 50 with $Z_T \stackrel{d}{=} \tilde{Y}_0$ (where $\stackrel{d}{=}$ denotes equality in distribution), the inequality $1 - \sigma_t \leq m_t$ for any $t \in [0, T]$, we have

$$\begin{aligned}
& \mathbb{E} \left[|Y_{t_K} - \tilde{Y}_{t_K}|^2 \right] \\
& \leq \mathbb{E} \left[|Y_0 - \tilde{Y}_0|^2 \right] + 2 \int_0^{t_K} \mathbb{E} \left[|Y_t - \tilde{Y}_t|^2 \right] dt - 4 \int_0^{t_K} \beta_{T-t}^{\text{OS}} \mathbb{E} \left[|Y_t - \tilde{Y}_t|^2 \right] dt \\
& \leq \mathbb{E} \left[|Y_0 - \tilde{Y}_0|^2 \right] e^{2[t_K-2] \int_0^{t_K} \beta_{T-t}^{\text{OS}} dt} \\
& = \mathbb{E} \left[|m_T X_0 + (\sigma_T - 1) \tilde{Y}_0|^2 \right] e^{2[t_K-2] \int_0^{t_K} \beta_{T-t}^{\text{OS}} dt} \\
& \leq 2 \left(\mathbb{E} \left[|X_0|^2 \right] + d \right) e^{2[t_K-2] \int_0^{t_K} \beta_{T-t}^{\text{OS}} dt - 2T}.
\end{aligned} \tag{54}$$

Using 54, Remark 10, and $t_K = T - \epsilon$, we have

$$\begin{aligned}
W_2(\mathcal{L}(Y_{t_K}), \mathcal{L}(\tilde{Y}_{t_K})) & \leq \sqrt{\mathbb{E} \left[|Y_{t_K} - \tilde{Y}_{t_K}|^2 \right]} \\
& \leq \sqrt{2} (\sqrt{\mathbb{E} \left[|X_0|^2 \right]} + \sqrt{d}) e^{-2 \int_\epsilon^T \beta_t^{\text{OS}, K, \mu} dt - \epsilon}.
\end{aligned} \tag{55}$$

Upper bound on $W_2(\mathcal{L}(\tilde{Y}_{t_K}), \mathcal{L}(Y_{t_K}^{\text{aux}}))$. Using Itô's formula, we have, for $t \in [0, T - \epsilon]$,

$$\begin{aligned}
d|\tilde{Y}_t - Y_t^{\text{aux}}|^2 & = 2 \langle \tilde{Y}_t - Y_t^{\text{aux}}, \tilde{Y}_t + 2 \nabla \log p_{T-t}(\tilde{Y}_t) - Y_t^{\text{aux}} - 2 s(T-t, \hat{\theta}, Y_t^{\text{aux}}) \rangle dt \\
& = 2 |\tilde{Y}_t - Y_t^{\text{aux}}|^2 dt + 4 \langle \tilde{Y}_t - Y_t^{\text{aux}}, \nabla \log p_{T-t}(\tilde{Y}_t) - \nabla \log p_{T-t}(Y_t^{\text{aux}}) \rangle dt \\
& \quad + 4 \langle \tilde{Y}_t - Y_t^{\text{aux}}, \nabla \log p_{T-t}(Y_t^{\text{aux}}) - s(T-t, \hat{\theta}, Y_t^{\text{aux}}) \rangle dt.
\end{aligned} \tag{56}$$

By integrating and taking the expectation on both sides in 56, using Corollary 9, Young's inequality with $\zeta \in (0, 1)$ and Assumption 4, we have

$$\begin{aligned}
\mathbb{E} \left[|\tilde{Y}_{T-\epsilon} - Y_{T-\epsilon}^{\text{aux}}|^2 \right] & = 2 \int_0^{T-\epsilon} \mathbb{E} \left[|\tilde{Y}_s - Y_s^{\text{aux}}|^2 \right] ds \\
& \quad + 4 \int_0^{T-\epsilon} \mathbb{E} \left[\langle \tilde{Y}_s - Y_s^{\text{aux}}, \nabla \log p_{T-s}(\tilde{Y}_s) - \nabla \log p_{T-s}(Y_s^{\text{aux}}) \rangle \right] ds \\
& \quad + 4 \int_0^{T-\epsilon} \mathbb{E} \left[\langle \tilde{Y}_s - Y_s^{\text{aux}}, \nabla \log p_{T-s}(Y_s^{\text{aux}}) - s(T-s, \hat{\theta}, Y_s^{\text{aux}}) \rangle \right] ds \\
& \leq \int_0^{T-\epsilon} 2(1+\zeta) \mathbb{E} \left[|\tilde{Y}_s - Y_s^{\text{aux}}|^2 \right] ds \\
& \quad - 4 \int_0^{t_K} \beta_{T-s}^{\text{OS}} \mathbb{E} \left[|\tilde{Y}_s - Y_s^{\text{aux}}|^2 \right] dt + 2\zeta^{-1} \varepsilon_{\text{SN}} \\
& \leq 2e^{2(1+\zeta)(T-\epsilon)-4 \int_0^{t_K} \beta_{T-t}^{\text{OS}} dt} \zeta^{-1} \varepsilon_{\text{SN}}.
\end{aligned} \tag{57}$$

Using 57, Remark 10, and $t_K = T - \epsilon$, we have

$$\begin{aligned}
W_2(\mathcal{L}(\tilde{Y}_{t_K}), \mathcal{L}(Y_{t_K}^{\text{aux}})) & \leq \sqrt{\mathbb{E} \left[|\tilde{Y}_{t_K} - Y_{t_K}^{\text{aux}}|^2 \right]} \\
& \leq \sqrt{2\zeta^{-1}} e^{(1+\zeta)(T-\epsilon)-2 \int_\epsilon^T \beta_t^{\text{OS}, K, \mu} dt} \sqrt{\varepsilon_{\text{SN}}}.
\end{aligned} \tag{58}$$

Upper bound on $W_2(\mathcal{L}(Y_{t_K}^{\text{aux}}), \mathcal{L}(\hat{Y}_t^{\text{EM}}))$. Using Itô's formula, we have, for $t \in [0, T - \epsilon]$,

$$\begin{aligned}
& d|Y_t^{\text{aux}} - \hat{Y}_t^{\text{EM}}|^2 \\
&= 2\langle Y_t^{\text{aux}} - \hat{Y}_t^{\text{EM}}, Y_t^{\text{aux}} + 2s(T - t, \hat{\theta}, Y_t^{\text{aux}}) - \hat{Y}_{\lfloor t/\gamma \rfloor \gamma}^{\text{EM}} - 2s(T - \lfloor t/\gamma \rfloor \gamma, \hat{\theta}, \hat{Y}_{\lfloor t/\gamma \rfloor \gamma}^{\text{EM}}) \rangle dt \\
&= 2|Y_t^{\text{aux}} - \hat{Y}_t^{\text{EM}}|^2 dt + 2\langle Y_t^{\text{aux}} - \hat{Y}_t^{\text{EM}}, \hat{Y}_t^{\text{EM}} - \hat{Y}_{\lfloor t/\gamma \rfloor \gamma}^{\text{EM}} \rangle dt \\
&\quad + 4\langle Y_t^{\text{aux}} - \hat{Y}_t^{\text{EM}}, s(T - t, \hat{\theta}, Y_t^{\text{aux}}) - s(T - t, \hat{\theta}, \hat{Y}_t^{\text{EM}}) \rangle dt \\
&\quad + 4\langle Y_t^{\text{aux}} - \hat{Y}_t^{\text{EM}}, s(T - t, \hat{\theta}, \hat{Y}_t^{\text{EM}}) - s(T - \lfloor t/\gamma \rfloor \gamma, \hat{\theta}, \hat{Y}_{\lfloor t/\gamma \rfloor \gamma}^{\text{EM}}) \rangle dt.
\end{aligned} \tag{59}$$

Integrating and taking the expectation on both sides in 59, using Young's inequality for $\zeta \in (0, 1)$, Cauchy Schwarz inequality, Assumption 3.a, Lemma 19, and Remark 1, we have

$$\begin{aligned}
\mathbb{E} \left[|Y_{T-\epsilon}^{\text{aux}} - \hat{Y}_{T-\epsilon}^{\text{EM}}|^2 \right] &\leq (2 + 3\zeta) \int_0^{T-\epsilon} \mathbb{E}[|Y_t^{\text{aux}} - \hat{Y}_t^{\text{EM}}|^2] dt + \zeta^{-1} \int_0^{T-\epsilon} \mathbb{E}[|\hat{Y}_t^{\text{EM}} - \hat{Y}_{\lfloor t/\gamma \rfloor \gamma}^{\text{EM}}|^2] dt \\
&\quad + 4K_3(1 + 2T^\alpha) \int_0^{T-\epsilon} \mathbb{E}[|Y_t^{\text{aux}} - \hat{Y}_t^{\text{EM}}|^2] dt \\
&\quad + 2\zeta^{-1} \int_0^{T-\epsilon} \mathbb{E}[|s(T - t, \hat{\theta}, \hat{Y}_t^{\text{EM}}) - s(T - \lfloor t/\gamma \rfloor \gamma, \hat{\theta}, \hat{Y}_{\lfloor t/\gamma \rfloor \gamma}^{\text{EM}})|^2] dt \\
&\leq (2 + 3\zeta + 4K_3(1 + 2T^\alpha)) \int_0^{T-\epsilon} \mathbb{E}[|Y_t^{\text{aux}} - \hat{Y}_t^{\text{EM}}|^2] dt \\
&\quad + \zeta^{-1} \gamma (T - \epsilon) C_{\text{EMose}, 2} + 8\zeta^{-1} \gamma^{2\alpha} (T - \epsilon) K_1^2 (1 + 4\mathbb{E}[|\hat{\theta}|^2]) \\
&\quad + 4\zeta^{-1} K_3^2 (1 + 2T^\alpha)^2 \int_0^{T-\epsilon} \mathbb{E}[|\hat{Y}_t^{\text{EM}} - \hat{Y}_{\lfloor t/\gamma \rfloor \gamma}^{\text{EM}}|^2] dt \\
&\leq (2 + 3\zeta + 4K_3(1 + 2T^\alpha)) \int_0^{T-\epsilon} \mathbb{E}[|Y_t^{\text{aux}} - \hat{Y}_t^{\text{EM}}|^2] dt \\
&\quad + \zeta^{-1} \gamma (T - \epsilon) C_{\text{EMose}, 2} (1 + 4K_3^2 (1 + 2T^\alpha)^2) \\
&\quad + 8\zeta^{-1} \gamma^{2\alpha} (T - \epsilon) K_1^2 (1 + 8\tilde{\varepsilon}_{\text{AL}} + 8|\theta^*|^2) \\
&\leq e^{(2+3\zeta+4K_3(1+2T^\alpha))(T-\epsilon)} \\
&\quad \times \left(\zeta^{-1} \gamma (T - \epsilon) C_{\text{EMose}, 2} (1 + 4K_3^2 (1 + 2T^\alpha)^2) \right. \\
&\quad \left. + 8\zeta^{-1} \gamma^{2\alpha} (T - \epsilon) K_1^2 (1 + 8\tilde{\varepsilon}_{\text{AL}} + 8|\theta^*|^2) \right).
\end{aligned} \tag{60}$$

Using 60 and $t_K = T - \epsilon$, we have

$$\begin{aligned}
W_2(\mathcal{L}(Y_{T-\epsilon}^{\text{aux}}), \mathcal{L}(\hat{Y}_{T-\epsilon}^{\text{EM}})) &\leq \gamma^{1/2} \zeta^{-1/2} (T - \epsilon)^{1/2} e^{(1+(3/2)\zeta+2K_3(1+2T^\alpha))(T-\epsilon)} \\
&\quad \times (C_{\text{EMose}, 2}^{1/2} (1 + 2K_3(1 + 2T^\alpha)) + 2\sqrt{2}K_1(1 + 8\tilde{\varepsilon}_{\text{AL}} + 8|\theta^*|^2)^{1/2}).
\end{aligned} \tag{61}$$

Final upper bound on $W_2(\mathcal{L}(Y_K^{\text{EM}}), \pi_D)$. Substituting 51, 55, 58, and 61 into 49, we have

$$\begin{aligned}
W_2(\mathcal{L}(Y_K^{\text{EM}}), \pi_D) &\leq (\sqrt{\mathbb{E}[|X_0|^2]} + \sqrt{d}) 2\sqrt{\epsilon} \\
&\quad + \sqrt{2}(\sqrt{\mathbb{E}[|X_0|^2]} + \sqrt{d}) e^{-2 \int_\epsilon^T \beta_t^{\text{OS}, K, \mu} dt - \epsilon} \\
&\quad + \sqrt{2\zeta^{-1}} e^{(1+\zeta)(T-\epsilon)-2 \int_\epsilon^T \beta_t^{\text{OS}, K, \mu} dt} \sqrt{\varepsilon_{\text{SN}}} \\
&\quad + \gamma^{1/2} \zeta^{-1/2} (T - \epsilon)^{1/2} e^{(1+(3/2)\zeta+2K_3(1+2T^\alpha))(T-\epsilon)} \\
&\quad \times (C_{\text{EMose}, 2}^{1/2} (1 + 2K_3(1 + 2T^\alpha)) + 2\sqrt{2}K_1(1 + 8\tilde{\varepsilon}_{\text{AL}} + 8|\theta^*|^2)^{1/2}).
\end{aligned} \tag{62}$$

The bound for $W_2(\mathcal{L}(\hat{Y}_K^{\text{EM}}, \pi_D)$ in 62 can be made arbitrarily small by appropriately choosing parameters including $\epsilon, T, \varepsilon_{\text{SN}}$ and γ . More precisely, for any $\delta > 0$, we first choose $0 < \epsilon < \epsilon_\delta$ with ϵ_δ given in Table 2 such that the first term on the right-hand side of 62 is

$$(\sqrt{\mathbb{E}[|X_0|^2]} + \sqrt{d})2\sqrt{\epsilon} < \delta/4. \quad (63)$$

Next, we choose $T > T_\delta$ with T_δ given in Table 2 such that the second term on the right-hand side of 62 is

$$\sqrt{2}(\sqrt{\mathbb{E}[|X_0|^2]} + \sqrt{d})e^{-2} \int_\epsilon^T \beta_t^{\text{OS}, K, \mu} dt - \epsilon < \delta/4. \quad (64)$$

Next, we turn to the third term on the right-hand side of 62. We choose $0 < \varepsilon_{\text{SN}} < \varepsilon_{\text{SN}, \delta}$ with $\varepsilon_{\text{SN}, \delta}$ given in Table 2 such that

$$\sqrt{2\zeta^{-1}}e^{(1+\zeta)(T-\epsilon)-2} \int_\epsilon^T \beta_t^{\text{OS}, K, \mu} dt \sqrt{\varepsilon_{\text{SN}}} < \delta/4. \quad (65)$$

Finally, we choose $0 < \gamma < \gamma_\delta$ with γ_δ given in Table 2 such that the fourth term on the right-hand side of 62 is

$$\begin{aligned} & \gamma^{1/2} \zeta^{-1/2} (T - \epsilon)^{1/2} e^{(1+(3/2)\zeta+2K_3(1+2T^\alpha))(T-\epsilon)} \\ & \times (C_{\text{EMose}, 2}^{1/2} (1 + 2K_3(1 + 2T^\alpha)) + 2\sqrt{2}K_1(1 + 8\tilde{\varepsilon}_{\text{AL}} + 8|\theta^*|^2)^{1/2}) < \delta/4. \end{aligned} \quad (66)$$

Using 63, 64, 65, and 66, we obtain $W_2(\mathcal{L}(\hat{Y}_K^{\text{EM}}, \pi_D) < \delta$. \square

Proof of Theorem 15. Using the splitting 49, the proof follows along the same lines of the Proof of Theorem 13 for the estimation of the error bounds of the terms $W_2(\pi_D, \mathcal{L}(Y_{t_K}))$, $W_2(\mathcal{L}(Y_{t_K}), \mathcal{L}(\tilde{Y}_{t_K}))$, and $W_2(\mathcal{L}(\tilde{Y}_{t_K}), \mathcal{L}(Y_{t_K}^{\text{aux}}))$. The error bound for $W_2(\mathcal{L}(Y_{t_K}^{\text{aux}}), \mathcal{L}(Y_K^{\text{EM}}))$ is derived along the same lines of Bruno et al. (2025, Proof of Theorem 10). Putting these four estimates together leads to 25 and 26. \square

D Modified Half-Normal Distribution

In this section, we recall the probability density function of the modified half-normal distribution, see e.g., Sun et al. (2023), used in Section 3.4.1 and defined as

$$g(x) = \frac{2\xi^{\frac{v}{2}} x^{v-1} \exp(-\xi x^2 + \psi x)}{\Psi\left(\frac{v}{2}, \frac{\psi}{\sqrt{\xi}}\right)}, \quad x \geq 0, \quad (67)$$

where $v, \xi > 0$, $\psi \in \mathbb{R}$, and the normalizing constant

$$\Psi\left(\frac{v}{2}, \frac{\psi}{\sqrt{\xi}}\right) := \sum_{n=0}^{\infty} \frac{\Gamma\left(\frac{v}{2} + \frac{n}{2}\right)}{\Gamma(n)} \frac{\psi^n \xi^{-n/2}}{n!},$$

is the Fox–Wright function (Fox, 1928; Wright, 1935). We point out that the half-normal distribution, truncated normal distribution, gamma distribution, and square root of the gamma distribution are all special cases of the modified Half-Normal distribution 67. The distribution 27 follows by taking the symmetric extension of 67, i.e. $g(|x|)/2$, and choosing $v = 1$ and $\psi = -1$.

E Table of Constants

Table 2 displays full expressions for constants which appear in Theorem 13 and Theorem 15.

Table 2: Explicit expressions for the constants in Theorem 13 and Theorem 15.

CONSTANT	DEPENDENCY	FULL EXPRESSION
C_1	$O(\sqrt{d})$	$2(\sqrt{\mathbb{E}[X_0 ^2]} + \sqrt{d})$
