IMPROVING LLM REASONING THROUGH SCALING IN FERENCE COMPUTATION WITH COLLABORATIVE VER IFICATION

Anonymous authors

Paper under double-blind review

ABSTRACT

Despite significant advancements in the general capability of large language models (LLMs), they continue to struggle with consistent and accurate reasoning, especially in complex tasks such as mathematical and code reasoning. One key limitation is that LLMs are trained primarily on correct solutions, reducing their ability to detect and learn from errors, which hampers their ability to reliably verify and rank outputs. To address this, we adopt a widely used method to scale up the inference-time computation by generating multiple reasoning paths and employing verifiers to assess and rank the generated outputs by correctness. To get a better understanding of different verifier training methods, we introduce a comprehensive dataset consisting of correct and incorrect solutions for math and code tasks, generated by multiple LLMs. This diverse set of solutions enables verifiers to more effectively distinguish and rank correct answers from erroneous outputs. The training methods for building verifiers were selected based on an extensive comparison of existing approaches. Moreover, to leverage the unique strengths of different reasoning strategies, we propose a novel collaborative method integrating Chain-of-Thought (CoT) and Program-of-Thought (PoT) solutions for verification. CoT provides a clear, step-by-step reasoning process that enhances interpretability, while PoT, being executable, offers a precise and error-sensitive validation mechanism. By taking both of their strengths, our approach significantly improves the accuracy and reliability of reasoning verification. Our verifiers, Math-Rev and Code-Rev, demonstrate substantial performance gains to existing LLMs, achieving state-of-the-art results on benchmarks such as GSM8k and MATH and even outperforming GPT-40 with Qwen-72B-Instruct as the reasoner.

1 INTRODUCTION

037

052

Large language models (Brown et al., 2020; Achiam et al., 2023; Touvron et al., 2023a;; Jiang et al., 2023; Team et al., 2024) have demonstrated exceptional performance across various natural language tasks. Notably, the reasoning tasks such as math problem solving (Cobbe et al., 2021; Hendrycks 040 et al., 2021), code completion (Austin et al., 2021; Chen et al., 2021), multi-modal reasoning (Yue 041 et al., 2024a; Liang et al., 2024a) have attracted significant attention from AI researchers. Since 042 reasoning is a critical component of many important high-level tasks, such as scientific discovery 043 (Liang et al., 2024a; Miret & Krishnan, 2024), world model (Hao et al., 2023), embodied agents 044 (Song et al., 2023), etc. However, even the most advanced LLMs still face challenges in complex multi-step reasoning problems (Zhang et al., 2024a; Shi et al., 2024; Trinh et al., 2024). To improve the performance of LLMs on reasoning, recent studies (Yu et al., 2024b; Yue et al., 2024b; Gou et al., 046 2024; Luo et al., 2023; Wei et al., 2024; Tang et al., 2024; Yue et al., 2024c) have mainly focused 047 on generating synthetic question-answering pairs from stronger LLMs like GPT-4 (Achiam et al., 048 2023) or utilizing human-annotated rationales (Toshniwal et al., 2024) for supervised fine-tuning. These approaches have achieved outstanding performance on reasoning benchmarks like GSM8k (Cobbe et al., 2021), MATH (Hendrycks et al., 2021; Lightman et al., 2023), MBPP (Austin et al., 051 2021), etc.

053 While these straightforward data generation methods have proven effective, these LLMs are primarily trained to produce outputs that align with the correct reasoning steps they encountered during 054 training. However, they lack a fundamental understanding of when and why a particular reasoning 055 step might be flawed. As a result, while LLMs can effectively mimic the structure of correct reason-056 ing paths, they often struggle to ensure the accuracy of these paths and may produce responses that 057 seem correct at first glance, but are flawed Liang et al. (2024b). This limitation poses challenges for 058 reliably generating the correct solution. As shown in Fig. 1, many LLMs have low accuracy when attempting to find a single solution using greedy decoding (i.e. pass@1). However, when allowing each model to generate 64 solutions (at different temperature settings), the correct answer is often 060 found among the sampled solutions, with a pass@1 rate (i.e. recall) exceeding 85%. A similar high 061 pass@1 rate has also been observed by (Li et al., 2024), where models like LLaMA2-7b-base (Tou-062 vron et al., 2023b), despite not being particularly strong in complex reasoning, demonstrate high 063 pass@64 on solving math problems. 064

This offers hope for addressing the reasoning 065 challenges of LLMs: scaling up the inference 066 compute by sampling multiple candidate solu-067 tions has emerged as a promising approach and 068 recently garnered significant attention (Zhang 069 et al., 2024b; Brown et al., 2024; Bansal et al., 2024). Rather than relying solely on the greedy 071 decoding output, these methods involve generat-072 ing multiple solutions for a given problem by al-073 tering the generation temperature or prompt, scor-074 ing each solution by a verifier, and selecting the 075 best one with the highest score. Such best-of-N strategies can significantly enhance both the 076 accuracy and reliability of LLM outputs. How-077 ever, prior studies often focus on specific datasets (e.g., MATH (Lightman et al., 2023; Wang et al., 079 2023)) or particular backbone generators (e.g., LLaMA (Hosseini et al., 2024) or Gemini (Luo 081

Figure 1: Comparison of greedy decoding accuracy and pass@1 out of 64 sampled solutions on GSM8k dataset with various LLMs.

et al., 2024)), which not only lead to the development of weak and ad-hoc verifiers tailored to certain cases Snell et al. (2024), but also limits comprehensive comparisons and systematic benchmarking of different verifier training methods.

In this paper, aiming at building better verifiers for more effective inference-time verification, we 085 introduce a comprehensive training dataset created by sampling outputs from multiple LLM reasoners of varying sizes and purposes. We then categorize them into correct and incorrect sets, and 087 use them to build verifiers that learn from the diverse solution patterns produced by different LLMs. 088 Since the methods for training verifiers are so crucial, we conduct a thorough comparison of two 089 key approaches: outcome reward models (ORMs) (Cobbe et al., 2021) and preference tuning (e.g., 090 DPO (Rafailov et al., 2024)). ORMs add extra computational heads with scalar outputs to the per-091 token logits of LLMs and train the model with a binary classification loss. In contrast, preference 092 tuning methods like DPO teach LLMs to learn from pairwise data and generate outputs that align 093 more closely with preferred responses. While preference-tuned LLMs cannot directly output scalar scores like ORMs, we can calculate the likelihood of generating certain solutions given the input 094 problem as the score of the solutions. Our experiments show that reference-free preference tuning 095 methods, such as SimPO (Meng et al., 2024), are the most effective for training verifiers. The result-096 ing verifiers for math reasoning and code reasoning are named Math Reasoning Ensembled Verifier (Math-Rev) and Code Reasoning Ensembled Verifier (Code-Rev) in this paper, respectively. 098

Moreover, based on our observation, we locate weakness of LLM-based verifiers, where they easily overlook the subtle calculation errors and inconsistencies in math reasoning, and struggle to verify 100 highly abstractive and structured codes. To address these limitations, we propose a novel method 101 named CoTnPoT to further make verification more comprehensive and powerful. Therefore, we 102 also explore the complementary strengths of step-by-step language-based solutions and code-based 103 programming solutions for verification purposes. Step-by-step language solutions, also known as 104 chain-of-thought (CoT) (Wei et al., 2022) format, are more descriptive and connected to natural 105 language. In contrast, program solutions, or program-of-thought (PoT) (Chen et al., 2023) format, 106 are highly abstract and structured, allowing for direct execution to identify runtime errors, but they 107 are more complex and difficult to read. To address these challenges and leverage the strengths of both

Figure 2: The workflow of our method. We first sample solutions from multiple LLM reasoners and then train verifiers using preference loss (Step 1). During inference, for math reasoning, we sample multiple CoT solutions per question and use a coder LLM to transform them into a PoT format. Then we filter out any CoT answers that do not match with their corresponding PoT results and feed the remaining CoT solutions to the verifier. For code reasoning, we concatenate the PoT solution and CoT description for LLM-based verifier. The solution with the highest score is selected as the final answer. An example of CoT and PoT solutions is attached.

130 131

formats, we propose a method named **CoTnPoT** that combines language and code answers during solution verification. Our findings indicate that CoT solutions, being more readable and interpretable by LLMs, enable verifiers to achieve higher performance. On the other hand, code-based solutions, which are executable and sensitive to errors, provide a critical signal when assessing the correctness of language solutions.

With CoTnPoT and Math-Rev, we achieve significantly better math reasoning verification performance than two baselines - Math-Shepard (Wang et al., 2023) and Math-Minos (Gao et al., 2024).
In summary, our contributions are twofold:

139 140 141

142

• We investigate various verifier training methods and establish that reference-free alignment methods are the most effective. Using SimPO, our developed Math-Rev and Code-Rev achieve stateof-the-art accuracy.

We propose a novel method that combines language and code answers for solution verification, achieving promising synchronization and further improving final accuracy. Using Qwen-72B-Instruct (Yang et al., 2024) as the backbone reasoner, our approach yields 95.6% and 76.9% accuracy on the GSM8k and MATH benchmarks, respectively.

147 148

2 OUR METHOD

149 150

The workflow of our method is presented in Fig. 2. After collecting a diverse set of solutions, including both correct and incorrect ones, we train our verifiers, which can be implemented using any open-weight auto-regressive LLM (e.g., Mistral-7B). During the inference stage, the reasoner LLM generates responses to an input question, and the verifier is applied to score multiple sampled solutions from the reasoner.

155 156

157

2.1 DATA COLLECTION FOR TRAINING VERIFIERS

Math Reasoning We use the training sets of GSM8k (Cobbe et al., 2021) and MATH (Hendrycks et al., 2021) as seed datasets and sample model solutions from multiple backbone models: (1) general-purpose LLMs, including Mistral (Jiang et al., 2023) and Phi3 (Abdin et al., 2024); and (2) math-specialized models, including InternLM2-Math (Ying et al., 2024) and MAmmoTH2-plus (Yue et al., 2024c). For each question in GSM8k and MATH, we sample 10 Chain-of-Thought

(CoT) solutions and remove duplicates. Using functions provided by (Ying et al., 2024), we extract answers from model predictions and compare them with ground truth, resulting in 159,778 correct and 100,794 incorrect solutions for the training of Math-Rev, with an average of 10.67 correct and 6.73 incorrect solutions per problem. For the evaluation on the MATH dataset, we follow Lightman et al. (2023) and use the subset - MATH500, the same as previous work Wang et al. (2023); Gao et al. (2024).

Code Reasoning Similarly, we utilize general-purpose LLMs, including LLaMA-3-8B (Touvron 170 et al., 2023b) and Phi3 (Abdin et al., 2024), and code-specialized models, including CodeGemma-7B-it (Team, 2024a) and CodeQwen1.5 (Team, 2024b). We select the training sets of MBPP (Austin 171 et al., 2021) and the Python subset of MagiCoder-75k (Wei et al., 2024) as seed datasets. In code 172 generation tasks, test cases are usually required to determine the correctness of solutions. The 173 original MBPP training set includes test cases, but the MagiCoder does not. To address this, we use 174 GPT-40 to generate test cases for each problem in the Python subset of MagiCoder-75k, retaining 175 only test cases that the reference solution passed. If no generated test case matches the reference 176 solution, we repeat the process with a temperature of 0.8 up to three times. This process results in 177 11,527 problems with test cases in the MagiCoder-75k dataset. We then generate 50 solutions for 178 each seed problem in both that subset and MBPP, resulting in 132,089 correct and 145,345 incorrect 179 solutions with an average of 11.10 correct and 12.21 incorrect solutions per problem, which are used 180 for training our Code-Rev.

181

168

182 183

2.2 TRAINING MATH-REV AND CODE-REV

The verifiers, implemented using LLMs (e.g., Mistral), need to be trained with appropriate training
 methods to ensure their effectiveness during inference. We extensively investigate various usable
 methods that are introduced next.

187

Reward-based: ORMs and PRMs. Following the widely accepted definition in (Uesato et al., 188 2022), there are two categories of reward-based methods for building verifiers: outcome-reward 189 models (ORMs) (Cobbe et al., 2021) and process-reward models (PRMs) (Lightman et al., 2023). 190 ORM, commonly used in RLHF (Ouyang et al., 2022), can produce scalar scores on model re-191 sponses, whereas PRM evaluates the reasoning path step-by-step. Despite better performance, PRMs 192 need to collect process supervision data, relying on either human annotation (Lightman et al., 2023) 193 or per-step Monte Carlo estimation (Wang et al., 2023), both of which are prohibitively expensive 194 to scale. Moreover, the PRM method requires the solution to be formatted as step-by-step reasoning 195 chains (Lightman et al., 2023; Wang et al., 2023; Luo et al., 2024), where steps need to be clearly 196 separated by special tokens or periods to be scored, thereby limiting the application scenario of PRM. Consequently, in this paper, we do not assign per-step scores on reasoning paths, but instead 197 calculate a final score for the whole solution. 198

199

Preference-tuning: DPO and Beyond. Direct Preference Optimization (DPO) (Rafailov et al., 200 2024) is one of the most popular offline preference optimization methods. Unlike ORM or PRM 201 which rely on learning an explicit reward model, DPO proposes a novel loss function based on pref-202 erence pairs, which reparameterizes the reward function and applies it into the Bradley-Terry 203 (BT) ranking objective. This innovation has inspired various follow-up studies, such as IPO (Azar 204 et al., 2024), KTO (Ethayarajh et al., 2024), CPO (Xu et al., 2024), and R-DPO (Gallego, 2024). 205 Besides them, the reference-free variants including ORPO (Hong et al., 2024) and SimPO (Meng 206 et al., 2024) argue that reference models in the above reward functions would incur additional mem-207 ory and computational costs and create discrepancy between the reward function and the generation 208 metric during inference.

209

Our Verifiers Training. Although those preference-tuning methods are primarily designated to align LLMs with human preferences, they can also be adapted for training verifiers (Hosseini et al., 2024). By feeding the backbone LLM of the verifiers with pairs of correct and incorrect solutions, designated as chosen and rejected outputs, and applying the mentioned training methods, the verifier can be trained to assign higher generation probabilities to correct solutions over incorrect ones. Then the probability can be served as a score for ranking solutions. In our paper, Math-Rev and Code-Rev are trained separately by their respective training data with one of the preference-tuning methods -

SimPO. We believe that such verifiers have a significant advantage over ORMs: it does not introduce additional training parameters and not change the goal of generation for LLMs, aligning better with the original usage of LLM.

2.3 INFERENCE ENHANCED BY VERIFICATION WITH COTNPOT

222 During the inference stage, after deploying our Math-Rev and Code-Rev verifiers, we identify distinct challenges in verifying math and code reasoning. For math reasoning, while model-based verifiers can effectively detect surface-level logical errors such as incorrect use of operators, numbers, 224 and methods, they struggle to catch subtle mistakes such as calculation errors and small inconsis-225 tencies. For example, the verifier LLM always give high score to 3.5 + 2.5 + 4.5 + 1.5 = 13, 226 where the left part of the equation is the correct solution and the result to it should be 12 instead 227 of 13. In code reasoning, the structured and abstract nature of code makes it difficult to read and 228 understand, leading verifiers to assign similar scores to different solutions, indicating their difficulty 229 in accurately identifying errors within the code. 230

To address these challenges, we propose a method called CoTnPoT, which enhances verification by leveraging the connection and complementary strengths of the Chain of Thought (CoT) and Program of Thought (PoT) solution formats.

For math reasoning, we use an external LLM, DeepseekV2-chat-Lite (Zhu et al., 2024), to transform CoT solutions S_{CoT} into PoT counterparts S_{PoT} based on problem descriptions Q,

$$S_{PoT} = CoderLLM(Q, S_{CoT}).$$
(1)

238 We choose DeepseekV2-chat-Lite because it obtains both strong math reasoning and coding capabil-239 ities and we need to apply them to translate CoT solutions into PoT programs for math problems. We 240 then verify whether the transformed final answer from the execution of S_{PoT} matches the final an-241 swer from S_{CoT} . Our motivation is that logical errors in S_{CoT} would cause run-time errors in S_{PoT} , 242 while calculation errors in S_{CoT} would result in mismatched answers between S_{CoT} and S_{PoT} , as 243 PoT solutions ensure calculation correctness by using the Python interpreter. This approach takes 244 advantage of the executable nature of program-based solutions.

245 For code reasoning tasks, we find that directly training verifiers on Python code alone leads to inferior performance. This may be due to the increased difficulty in reading and understanding 246 code compared to human language, which can make it harder to detect reasoning errors. Therefore, 247 we use the same LLM to generate both the code solution S_{PoT} and the corresponding step-by-248 step description S_{Des} that explains why the solution is correct. Because using the same LLMs 249 for both code and description generation reduces over-reliance on external LLMs (we have to use 250 external LLMs for some math LLMs because they cannot generate codes). During both training 251 and inference and code verification, we concatenate the description and the code as an integrated input for the verifier, as shown in Equation 2. This method provides richer information in the code 253 solutions, making the LLM-based verification process more effective. 254

$$S_{Des} = CoderLLM(Q, S_{PoT})$$
⁽²⁾

We summarize the outline of CoTnPoT for Math Reasoning:

- Sample multiple CoTs S_{CoT} : Generate CoT solutions for the given math problem.
- Translate S_{CoT} into S_{PoT} : Use DeepseekV2-chat-Lite to transform each S_{CoT} into a corresponding PoT solution S_{PoT} based on the problem description Q, as defined in Equation 1.
- Filter S_{CoT} out if its answer does not match S_{PoT} : Check if the final answer from executing S_{PoT} matches the answer of S_{CoT} . Discard any S_{CoT} where a mismatch occurs, as it likely contains calculation errors.
- LLM-based Verifier on the remaining S_{CoT} : Apply an LLM-based verifier on the filtered S_{CoT} solutions to further assess logical consistency.

Outline of CoTnPoT for code Reasoning:

• Sample multiple PoTs S_{PoT} : Generate PoT solutions for the coding problem.

- Write Description S_{Des} based on S_{PoT} : Use coder LLM to generate a descriptive explanation S_{Des} that justifies the correctness of S_{PoT} .
 - Concatenate S_{PoT} and S_{Des}: Combine the code solution and its description into a single input for verification.
 - LLM-based Verifier on the concatenated input: Apply an LLM-based verifier to the concatenated S_{PoT} and S_{Des} to enhance error detection accuracy.

3.1 EXPLORING DIFFERENT TRAINING METHODS FOR VERIFIERS

281 **Experiment Setting.** For all experiments in Figure 3, we use the latest Mistral-7B-instruct-v0.3 282 as the backbone LLM for building the verifiers and apply LoRA with a dropout rate of 0.1 to reduce 283 the computational load during verifier training. The training batch size is set to 64, and the learning 284 rate to 0.00002 for all verifiers. For ORM, we add an additional computational head on the per-token 285 logits from the backbone LLM, outputting a scalar value for each token. We take the score of the last token as the final score, which has shown better performance than averaging them based on our 286 observations. For DPO and its variants, we construct preference pairs by randomly selecting correct-287 incorrect solutions for the same problem from the training set. We use 8 A100-40G GPUs for all the 288 experiments and employ vLLM to optimize the inference speed. The training of the verifiers takes 5 289 hours approximately. We first perform supervised fine-tuning on all correct solutions and then apply 290 preference loss on the preference set. 291

292 **LLM Reasoners in Evaluation.** To evaluate the reasoning performance on the GSM8k dataset, 293 we use LLaMA2-7B-base and Mistral-7B-v0.1, both fine-tuned on GSM8k, along with Gemma-7Bit, Phi-14B, InternLM2-Math-7B, and LLaMA3-70B as our reasoners. For LLaMA2 and Mistral, 295 we sample 100 solutions per problem for voting and verification, while 64 solutions are generated 296 for the rest. On the MATH dataset, which contains much harder problems than GSM8k, we replace 297 LLaMA2-7B-base and Mistral-7B-v0.1 with LLaMA3-8B-instruct and Mistral-7B-v0.3 for their 298 superior reasoning ability, along with other four reasoners. For all problems in MATH500, we 299 generate 64 solutions individually. All LLM output sampling in our paper is based on a temperature of 0.8 and top-p of 0.95. 300

Experimental Results. The results are 302 shown in Figure 3. We observe that the veri-303 fiers consistently improve the greedy decoding 304 baseline, especially for weaker reasoners 305 such as LLaMA2-7B. We also evaluate in-306 distribution (ID) LLMs, which are the source 307 LLMs used to generate the training data for 308 verifiers, such as Mistral, InternLM2-Math, 309 and Phi, and out-of-distribution (OOD) LLMs, such as LLaMA2-7B and Gemma-7B. The 310 results show no significant difference between 311 ID and OOD performance improvement by 312 verifiers, suggesting that our approach can ex-313 tend to any LLM reasoners and is not limited to 314 the LLMs that generate the training data. Fur-315 thermore, preference-tuning-based verifiers, 316 including DPO and SimPO, outperform ORM, 317 similar to the findings in Hosseini et al. (2024).

Figure 3: Performance of different verifiers (all better than greedy decoding)

The potential reason is that DPO and SimPO train LLMs without changing their structure, thus aligning better with their previous training goals of auto-regressive text generation. Additionally, ORPO and SimPO consistently outperform DPO, potentially because the regularization term on the reference model in the DPO loss might negatively impact verifier training. In other words, we do not need to control the divergence of the SFT model and the final verifier because it will not be used for text generation anymore. Therefore, we can conclude that the reference-free method is more suitable for verifier training.

Additionally, preference-tuning methods such as DPO and SimPO theoretically enable autoregressive LLMs to generating solutions. However, we observe that the generation ability of verifiers trained with preference pairs degrades rapidly, rendering them incapable of generating coherent sentences. This observation is also consistent with the findings in Hosseini et al. (2024). We attribute this degradation to that the verifier training process involves more steps and larger learning rates than typical alignment practices, which likely causes the verifier's weights to diverge significantly from the fine-tuned checkpoint. Consequently, these verifiers lose their generation capability and are instead better suited for calculating the likelihood of pre-generated solutions.

3.2 EVALUATION OF VERIFIERS WITH COTNPOT

372 This section focuses on evaluating the inference performance using the trained verifiers with the de-373 signed CoTnPoT filtering. In this section, we upgraded the backbone model of our verifier for math 374 reasoning from Mistral-7B to MAmmoTH-7B-plus (Yue et al., 2024c). This change was motivated 375 by two key factors: (1) using a more advanced model can enhance verification performance, and (2) 376 employing a different model demonstrates the generalization capability of our training method. We acknowledge that this adjustment may raise questions, but we are confident that it does not affect 377 the overall conclusions of the paper.

Table 2: Performance of different verification strategies on Code-Rev. We compare the performance
 on using the MBPP training set alone and incorporating MagiCoder, and the verification on code
 solution only and solution with CoTnPoT comments. Left and right numbers are top-1 pass rates
 on MBPP and MBPP+, respectively. The green arrows denote the percentage change compared to
 greedy decoding performance.

| | Codegemma | Phi | LLaMA3 | CodeQwen | DeepseekCoder |
|------------------|-------------------|-------------------|---------------------|-------------------|-------------------|
| MBPP | 64.2/53.9 | 72.2/58.3 | 60.4/51.2 | 75.7/65.7 | 72.0/60.8 |
| w/o CoTnPoT | ↓ 8.81% / ↓ 5.27% | ↑ 0.14% / ↑ 1.04% | ↓ 13.84% / ↓ 13.66% | ↓ 4.66% / ↓ 4.78% | ↓ 4.26% / ↓ 2.25% |
| MBPP | 67.6/55.4 | 74.9/60.0 | 66.2/54.8 | 79.5/69.6 | 73.9/62.6 |
| w CoTnPoT | ↓ 3.98% / ↓ 2.64% | ↑ 3.88% / ↑ 3.99% | ↓ 5.56% / ↓ 7.59% | ↑ 0.13% / ↑ 0.87% | ↓ 1.73% / ↑ 0.64% |
| MBPP + MagiCoder | 65.1/54.8 | 73.7/58.4 | 63.3/52.6 | 77.5/66.5 | 73.0/62.2 |

| MBPP + MagiCoder | 70.9/58.3 | 75.2/60.5 | 72.7/62.0 | 80.3/71.1 | 77.5/67.3 |
| w CoTnPoT | ↑ 0.71% / ↑ 2.46% | ↑ 4.30% / ↑ 4.85% | ↑ 3.71% / ↑ 4.55% | ↑ 1.13% / ↑ 3.04% | ↑ 3.06% / ↑ 8.20% |

Math Reasoning. We further enhance the inference process by combining majority voting with verifier scores, using the scores from verifiers as weights in the voting process. Specifically, we apply Gumbel Softmax (Gumbel, 1958; Jang et al., 2022) with the hyperparameter τ to regulate the influence of verifier-based scores, as shown in Equation 3.

$$y_i = \frac{\exp\left(\frac{\log(\pi_i)}{\tau}\right)}{\sum_{j=1}^k \exp\left(\frac{\log(\pi_j)}{\tau}\right)}$$
(3)

where π_i represents the unnormalized log probabilities for the *i*-th solution. Theoretically, if τ is set to an infinitely large value, the weighted voting will be equivalent to majority voting. If τ is close to zero, the result will depend solely on the verifier scores. We perform a grid search on τ values from the set {0.1, 0.5, 1, 5, 10} for GSM8k and MATH datasets separately, finding that 0.5 works best for GSM8k and 10 works best for MATH. This implies that for simpler problems like those in GSM8k, we can rely more heavily on verifiers, while for more complex datasets like MATH, the original model outputs should be weighted more significantly.

408 As shown in Table 1, blue percentages indicate performance improvements over the baseline with-409 out CoTnPoT, and green percentages indicate improvements over greedy decoding. Generally, we observe that the final column, Weighted Voting + CoTnPoT, consistently outperforms all base-410 lines across all reasoners. CoTnPoT brings improvements to most backbone reasoners and both 411 datasets, demonstrating its effectiveness in filtering incorrect solutions. Notably, CoTnPoT provides 412 a substantial performance boost for weaker reasoners but is less impactful as the reasoners become 413 stronger. This is reasonable because verifying and filtering solutions for strong LLMs is a more 414 challenging task compared to for weaker ones. 415

415

394

395

Code Reasoning. In addition to using PoT to verify and filter CoT answers, we also explore leveraging CoT descriptions to improve code solution verification.

As shown in Table 2, incorporating CoTnPoT descriptions into the verification process leads to 419 significant improvements across all LLM reasoners. We believe that the generated descriptions 420 enrich the information within the solution, enhancing the verifier's understanding of the solution. An 421 ablation study was conducted on the additional training set, i.e., MagiCoder-75k. The experiments 422 show that MagiCoder-75k serves as a valuable additional training resource for coding benchmarks 423 like MBPP. Moreover, we observe that greedy decoding is already a strong baseline for coding tasks, 424 and our verifier-based approaches usually fall short, likely due to the abstractness and obscureness 425 of codes. That is also the reason why our proposed CoTnPoT-based strategy is effective, i.e., we 426 provide high-granularity explanations to clarify the solutions.

- 427
- 428 3.3 COMPARISON WITH VERIFIER BASELINES

We compare our math verifier, Math-Rev, with two recent baselines, Math-Shepard and Math-Minos.
 We follow their methodology and use a consistent LLM reasoner, MetaMath-7B-Mistral. Although there is a slight difference in that we sampled 64 solutions per problem whereas they sampled 256

Table 3: Our verifier Math-Rev outperforms two baselines with fewer solutions sampled per problem
on both GSM8k and Math500 datasets, demonstrating the effectiveness of our verifier training and
CoTnPoT verification.

| 435 | | | |
|-----|--|-------|---------|
| 436 | Mistral-7B-MetaMath Results | GSM8k | MATH500 |
| 437 | Major Voting @ 64 | 83.50 | 35.00 |
| 438 | Major Voting @ 256 | 83.90 | 35.10 |
| 430 | Math-Shepherd @ 256 (Wang et al., 2023) | 87.10 | 37.30 |
| | Math-Shepherd + Voting @ 256 (Wang et al., 2023) | 86.30 | 38.30 |
| 440 | ORM + PPO + Voting @ 256 (Wang et al., 2023) | 89.00 | 43.10 |
| 441 | Math-Shepherd + PPO + Voting @ 256 (Wang et al., 2023) | 89.10 | 43.50 |
| 442 | Math-Minos (ORM) @ 256 (Gao et al., 2024) | 87.30 | 37.40 |
| 443 | Math-Minos (PRM) @ 256 (Gao et al., 2024) | 87.60 | 37.80 |
| 444 | Math-Minos (ORM) + Voting @ 256 (Gao et al., 2024) | 88.20 | 38.30 |
| | Math-Minos (PRM) + Voting @ 256 (Gao et al., 2024) | 87.80 | 38.60 |
| 445 | Math-Rev (Ours) @ 64 | 90.37 | 46.60 |
| 446 | Math-Rev + CoTnPoT (Ours) @ 64 | 90.75 | 46.40 |
| 447 | . / | | |

solutions, our verifier Math-Rev still achieves the best performance, as shown in Table 3. This
success is attributed to the more effective verifier training method, SimPO, and the pairwise training
data sampled from multiple LLM reasoners. Another notable finding is that our CoTnPoT method
poses a slightly negative impact on the MATH500 dataset, the reason is that CoTnPoT is less helpful
on stronger backbone reasoners, as also shown in Table 1. However, it does not hinder its general
applicability demonstrated in Table 1 and still has the potential to improve by switching the coder
model that translates CoT to PoT to stronger ones.

3.4 COMPARISON OF COTNPOT WITH BEST-OF-N AND BEST-OF-2N

Table 4: Comparison of performance for Best-of-N, Best-of-2N, and Best-of-N + CoTnPoT on GSM8k and MATH datasets.

| Doct of N | Dect of IN | Doct of N + CoTpDoT |
|------------|---|--|
| Dest-01-IN | Dest-01-21N | Dest-01-in + Collipsil |
| 75.21 | 76.75 | 78.01 |
| 87.87 | 88.65 | 89.54 |
| 75.06 | 77.02 | 78.54 |
| 91.03 | 91.03 | 92.49 |
| 45.00 | 45.60 | 45.80 |
| 32.60 | 35.20 | 35.40 |
| 32.80 | 34.00 | 39.20 |
| 62.00 | 63.60 | 63.60 |
| - | Best-of-N 75.21 87.87 75.06 91.03 45.00 32.60 32.80 62.00 | Best-of-N Best-of-2N 75.21 76.75 87.87 88.65 75.06 77.02 91.03 91.03 45.00 45.60 32.60 35.20 32.80 34.00 62.00 63.60 |

Table 4 presents the comparison between Best-of-N, Best-of-2N, and Best-of-N + CoTnPoT across various backbone reasoners with N=64. The results show that Best-of-2N consistently outper-forms Best-of-N, indicating the benefits of an increased sampling budget in improving performance. However, Best-of-N + CoTnPoT achieves even higher performance than Best-of-2N in most cases, demonstrating the effectiveness of CoTnPoT, which refines outputs by leveraging an additional coder LLM rather than merely doubling the sampling budget. These findings suggest that CoTnPoT offers a computationally efficient yet impactful approach to improving performance compared to simply increasing the sampling budget.

- 4 RELATED WORK

```
4.1 SCALING UP INFERENCE-TIME COMPUTING
```

485 Cobbe et al. (2021) is the pioneering work that applies verifiers in mathematical reasoning, where they train token-level reward models to give scores on problem solutions. Then Uesato et al. (2022);

486 Lightman et al. (2023) dive into the application of PRM - process reward models, where scores 487 are assigned to each intermediate step of solutions, providing more fine-grained feedback. Math-488 Shepherd (Wang et al., 2023) and MiPS (Wang et al., 2024b) propose using Monte-Carlo Tree-489 Search (MCTS) to automate the data collection process instead of human labeling. OVM Yu et al. 490 (2024a) employs outcome supervision for training a value model, which prioritizes steps that lead to accurate conclusions during inference. V-Star (Hosseini et al., 2024) presents an iterative frame-491 work in LLM training, which collects both correct data for supervised fine-tuning and wrong data 492 for verifier training. They also showed that DPO is stronger than ORMs in verification. Built on 493 reranking strategies such as verifiers, multiple studies Brown et al. (2024); Snell et al. (2024) found 494 that scaling up inference-time computing is much more cost-effective than training. To achieve more 495 effective and efficient inference-time verification, our approach samples solutions from various LLM 496 reasoners and comprehensively compares different verifier training methods. Our best verifier Math-497 Rev achieves strong performance on math solution verification using only outcome-based labels in 498 training and even outperforms PRM baselines.

4.2 CONNECT BETWEEN CHAIN-OF-THOUGHT AND PROGRAM-OF-THOUGHT

PAL (Gao et al., 2023) and PoT (Chen et al., 2023) are two early studies that incorporate Python 503 programs into LLM reasoning. MathCoder (Wang et al., 2024a) proposes a method of generating 504 novel and high-quality datasets with math problems and their code-based solutions. As for the code-505 based verification and feedback, Zhou et al. (2024a) employs a zero-shot prompt on GPT-4 Code 506 Interpreter to encourage it to use code to self-verify its answers. Zhou et al. (2024b) autoformalizes 507 informal mathematical statements into formal Isabelle code to verify the internal consistency. ART 508 (Miao et al., 2024) introduces relation tuples into the reasoning steps and verifies them with code 509 interpreter to provide feedback, finally improving reasoning accuracy. Compared to existing work 510 (Zhou et al., 2024a;b), our paper does not explicitly prompt the model to verify language solutions in code format. Instead, we ask the model to translate between math and code, which is an easier 511 task for LLMs than verification, yet yields better performance. Also, our approach extends beyond 512 math reasoning, proving effective in code reasoning as well, thereby suggesting broader applicabil-513 ity. Unlike previous studies, we are the first to examine the effectiveness of combining CoT and 514 PoT methods in verification, demonstrating promising results across both mathematical and code 515 reasoning tasks. 516

517 518

519

5 CONCLUSION

520 In this paper, we address the challenge of improving reasoning verification in LLM by integrating 521 CoT and Program-of-Thought PoT. Firstly, we collect a comprehensive binary dataset, derived from 522 multiple LLM reasoners for both math and code reasoning tasks, providing a robust foundation for 523 training verifiers. Next, through an extensive comparison of outcome reward models (ORMs) and 524 preference-tuning methods, we identify that reference-free preference tuning, particularly SimPO, 525 offers superior performance. Moreover, we introduce techniques to generate CoT/PoT based on their 526 PoT/CoT counterparts for further verification. Our resulting verifiers, Math-Rev and Code-Rev, 527 outperform existing baselines and achieve state-of-the-art results on benchmarks such as GSM8k 528 and MATH. We believe this paper could serve as a strong baseline in reasoning verification and 529 facilitate future studies on reasoning, verifying, reinforcement learning and related areas.

530

531 **Limitation** While our approach demonstrates significant improvements in reasoning verification, 532 it also comes with certain limitations. First, the sampling and re-ranking strategy introduces ad-533 ditional computational overhead compared to greedy decoding, which can be resource-intensive, 534 especially when applied to large-scale datasets or deployed in real-time applications. Secondly, our 535 verifier is based on an outcome reward model (ORM) that provides feedback at the solution level 536 rather than at the step level. This solution-level granularity, while effective in overall verification, 537 lacks the finer granularity of process reward models (PRMs) that evaluate each step of the reasoning path. PRMs can potentially offer more detailed feedback and facilitate more precise corrections, 538 particularly in complex multi-step reasoning tasks. However, implementing step-level verification would require extensive process supervision data, which is expensive and challenging to scale.

A APPENDIX

757 758 759

756

A.1 ABLATION STUDY ON COTNPOT

760761 In this section, we compare our proposed CoT-

nPoT with two ablated approaches:

A1. Prompting the same coder LLM to generate the final answer directly through code, and filtering

out CoT solutions that do not match the code solution. This ablation isolates the scenario where the
 coder LLM relies solely on its inherent strong math problem-solving ability, instead of analyzing
 and transforming the CoT solution.

A2. Prompting the same coder LLM to generate descriptions that analyze the CoT solutions and assess their correctness. This approach intuitively leverages LLMs as filters for verification.

We implement and compare CoTnPoT, A1, and A2 across all settings and both datasets in Figure 4. The accuracy is averaged at the dataset level for better visibility. We observe that CoTnPoT consistently outperforms both A1 and A2. The potential reason is that the task of translating CoT solutions to PoT solutions is easier and requires less reasoning than the processes in A1 and A2. Therefore, although A1 and A2 are more direct methods to verify a solution, their performance is limited by the capability of the coder LLM. On the other hand, CoTnPoT relies less on complex reasoning, making it more effective overall.

781 782

783 784

A.2 ANALYSIS ON COTNPOT

Our method, CoTnPoT, for math reasoning is designed to filter out low-quality solutions by examining the match between CoT and PoT solutions. This approach essentially functions as a binary classification task. By defining the ground truth label of a correct CoT solution as 1 and an incorrect CoT solution as 0, the correspondence between CoT and PoT solutions is used as the prediction label, where a match is labeled as 1 and a mismatch as 0. The effectiveness of the CoTnPoT filter is directly correlated to the performance of this binary classifier, aiming to retain all solutions labeled as 1 and discard those labeled as 0.

| | Actually Positive: Correct CoT Solution | Actually Negative: Wrong CoT Solution |
|---|--|--|
| Predicted Positive: CoTnPoT Match | True Positives (TPR): 90.09% | False Positives (FPR): 20.30% |
| Predicted Negative: CoTnPoT Mismatch | False Negatives (FNR): 9.91% | True Negatives (TNR): 79.70 |

799 800

792 793 794

796 797 798

801 To validate this method, we randomly selected 50,000 correct and 50,000 incorrect CoT solutions 802 from our verifier training set and applied the CoTnPoT filter. The performance of the classifier is 803 summarized in the confusion matrix presented in Table 5. The results demonstrate that the CoTnPoT 804 classifier effectively identifies correct solutions, as evidenced by high True Positive Rate (TPR) and 805 False Negative Rate (FNR). While the False Positive Rate (FPR) and True Negative Rate (TNR) are 806 moderate, indicating some incorrect solutions are not filtered out, the majority of correct solutions 807 are preserved for further verification. This experiment provides strong evidence of the significant performance improvement that the CoTnPoT-based filter brings to math reasoning. Figure 6 in the 808 appendix shows the examples of true positive, false negative, false negative, and true negatives of the above CoTnPoT classifier.

A.3 QUALITATIVE ANALYSIS: ERROR DETECTION IN SOLUTIONS

In this experiment, we evaluated the performance of our Math-Rev verifier in identifying and highlighting errors in mathematical solutions. Each column in the provided figure represents a math
problem, including both a correct solution and a deliberately modified incorrect solution. We input both solutions into our Math-Rev verifier, and highlight tokens in the wrong solution with log
probabilities less than -10 in red to indicate detected errors, as shown in Figure 5.

| 817 | | |
|-----|--|---|
| 818 | Question: | Question: |
| 819 | Tracy feeds each of her two dogs 1.5 cups of food per meal. She feeds | Tonya has opened a lemonade stand selling lemonade in small, medium, and large cups at \$1, \$2 and \$3 respectively. At the close of husiness the ended up making \$50. As she |
| 820 | consume if 1 pound is equal to 2.25 cups? | went back through her inventory she noticed that she sold \$11 worth of small lemonades and \$24 worth of medium lemonades. How many curs of large lemonade did Tonya sell? |
| 821 | Correct Solution: | Correct Solution: |
| 822 | | |
| 823 | Tracy feeds each dog 1.5 cups of food per meal, and she has two dogs, so they eat a total of $1.5 \times 2 = 3$ cups per meal. | lonya sold \$11 worth of small lemonades, which means she sold \$11/\$1 = 11 small lemonades. |
| 824 | She feeds her dogs three times a day, so in one day they eat a total of 3 x 3 = 9 cups of food. | She also sold \$24 worth of medium lemonades, which means she sold \$24/\$2 = 12 medium lemonades. |
| 825 | If 1 pound is equal to 2.25 cups, then the number of pounds their food consumption is 9 / 2.25 = 4 pounds. | Tonya made a total of \$50, so the amount she made from selling large lemonades is \$50 - \$11 - \$24 = \$15. |
| 826 | So Tracy's dogs consume 4 pounds of food each day. The answer is: \$4\$ | Since each large lemonade costs \$3, Tonya sold \$15/\$3 = 5 large lemonades. |
| 827 | Wrong Solution: | Wrong Solution: |
| 828 | | |
| 829 | Tracy feeds each dog 1.5 cups of food per meal, and she has two dogs, so they eat a total of 1.5 x 2 = 3 cups per meal. | Tonya sold \$11 worth of small lemonades, which means she sold \$11/\$1 = 11 small lemonades. |
| 830 | She feeds her dogs three times a day, so in one day they eat a total of 3 x $3 = 9$ cups of food. | She also sold \$24 worth of medium lemonades, which means she sold \$24/\$2 = 12 medium lemonades. |
| 831 | If 1 pound is equal to 2.25 cups, then the number of pounds their food consumption is 9 x 2.25 = 20.25 pounds. | Tonya made a total of \$50, so the amount she made from selling large lemonades is \$50 - \$11 - \$24 = \$15. |
| 832 | So Tracy's dogs consume 20.25 pounds of food each day. The answer is: | Since each large lemonade costs \$3, Tonya sold \$15/ \$2 = 7.5 large lemonades. |
| 833 | 10000 | |

Figure 5: The figure illustrates two mathematical problems, each paired with a correct solution and
an intentionally incorrect solution. The Math-Rev verifier highlights errors in the incorrect solutions
in red, effectively identifying and marking the parts with low log probabilities.

For the first problem, Math-Rev successfully identified the incorrect use of the multiplication operator and also recognized the incorrect final answer, highlighting these segments in red. This indicates
the verifier's sensitivity to mathematical operations and the final conclusion drawn from these operations. In the second problem, the verifier detected the discrepancy in the calculations and identified the deviation from the problem's requirements, marking the erroneous parts accordingly. This
demonstrates Math-Rev's effectiveness in pinpointing computational errors and inconsistencies with
problem statements.
