# Scenarios and Approaches for Situated Natural Language Explanations

Anonymous ACL submission

#### Abstract

Large language models (LLMs) can be used to generate natural language explanations (NLE) that are adapted to different users' situations. However, there is yet to be a quantitative eval-005 uation of the extent of such adaptation. To bridge this gap, we collect a benchmarking dataset, SITUATION-BASED EXPLANATION. 007 This dataset contains 100 explanandums. Each explanandum is paired with explanations targeted at three distinct audience types-such as educators, students, and professionals-enabling 011 us to assess how well the explanations meet the specific informational needs and contexts of these diverse groups e.g. students, teachers, and parents. For each "explanandum paired with an audience" situation, we include a humanwritten explanation. These allow us to compute 017 scores that quantify how the LLMs adapt the explanations to the situations. On an array of pretrained language models with varying sizes, we examine three categories of prompting methods: rule-based prompting, meta-prompting, and in-context learning prompting. We find that 1) language models can generate prompts that result in explanations more precisely aligned with the target situations, 2) explicitly modeling an "assistant" persona by prompting "You 027 are a helpful assistant..." is not a necessary prompt technique for situated NLE tasks, and 3) the in-context learning prompts only can help LLMs learn the demonstration template but can't improve their inference performance. SBE and our analysis facilitate future research towards generating situated natural language explanations.

#### 1 Introduction

Recently, LLMs have shown promising abilities to reason about complex phenomena and explain them in fluent natural languages. The produced natural language explanations (NLEs)<sup>1</sup> can be highly accu-

Figure 1: Different audiences need different explanations.

rate (Narang et al., 2020), informative (Wiegreffe et al., 2022), plausible (Chan et al., 2022; Marasovic et al., 2022) and reasonably faithful (Lyu et al., 2023). These desirable properties lead to wide potential applications that use LLMs as building blocks for explainer tools.

The explainer tools are closely relevant to the users, which make some properties particularly desirable, for example, helpful for answering unseen instances (Joshi et al., 2023) and for fact-checking (Si et al., 2024). In this paper, we are particularly interested in situatedness: the explanations of the same phenomena can and should be tailored to the audience. This principle is well-established in the literature of psychology, education, and communication (e.g., the Cognitive Load Theory (van Merriënboer and Sweller, 2005)), and is prevalent in writing guides (Purdue; Stephen et al., 2022; Cutts, 2020), even in government's writing guide-lines (Administration, 2011).

Recent work by Zhu et al.'s (2023) explored using pretrained language models for generating

041

100

In this paper, we aim to bridge both gaps. We introduce a novel benchmarking dataset called SITUATION-BASED EXPLANATION (SBE for short). This dataset contains 100 explananda (concepts or phenomena to be explained), each paired with three potential audiences. For each unique combination of explanandum and audience, we provide a human-written explanation, allowing us to compute similarity scores and a matching score that quantify how well the language models adapt the explanations to the target situations. Using SBE, we systematically evaluate the performance of various pretrained language models across three categories of prompting methods: rulebased prompting, meta-prompting, and in-context learning prompting. Through this analysis, we uncover the strengths and limitations of different prompting techniques in generating situated NLEs. Our key contributions are:

- 1. We provide SBE, a dataset facilitating systematic study of the situated adaptation effects of NLE.
- 2. We quantify the effects of several prompting techniques for generating situated explanations with LLMs.

By introducing SBE and rigorously evaluating the performance of various LLMs and prompting methods, this work paves the way for future research towards more effective and situationally appropriate natural language explanations.

# 2 Related Work

**Natural language explanation** Natural language explanations (NLEs) have been widely studied

for various high-level reasoning tasks, such as inference (Camburu et al., 2020), commonsense multiple-choice questions (Rajani et al., 2019), question-answering (Aggarwal et al., 2021), and product recommendations (Li et al., 2020). Wiegreffe and Marasovic (2021) provided a comprehensive review of datasets for NLEs, highlighting desirable properties of NLEs including simplicity (Lombrozo, 2007), clarity, and informativeness (Clinciu et al., 2021). We consider a different property: the extent of adaptation to the situational contexts of the explanations' readers. 101

Human-centered explanation Despite the numerous methods proposed to make AI more explainable, most focus on mechanistic approaches, whose utilities are subject to increasing concerns that these methods fail to consider the cognitive and contextual needs of users. Multiple researchers have called for greater consideration of human factors when explaining AI (Liao et al., 2022; Boyd-Graber et al., 2022; Yeung et al., 2020; Miller, 2019; Ehsan et al., 2024; Goyal et al., 2023). Building upon this line of research, we develop NLE methods that are technically accurate and effectively communicate with and meet the needs of human users. Explainable recommendation is also a related research direction, where the personification of explanation would be beneficial for recommendation systems (Geng et al., 2022a,b). We consider a wide range of scenarios, and our findings can be applied to explainable recommendations.

**Cultural and societal knowledge** This paper is related to the works about the pragmatics of LMbased communication tools. Yerukola et al. (2024) considered the abilities to infer the speakers' intents. Rao et al. (2024) considered the cultural adaptabilities of LLMs. Liu et al. (2024) found that LLMs are less steerable when personified to stances associated with apparently incongruous traits. We focus on daily-life scenarios without the cross-cultural differences. Our work is also closely
related to researches that assess the societal intelligence of LLM-based language generation systems,
including Wang et al. (2024) which simulated societal interactions between LLM-based agents. We
focus on the situated adaptation of NLE.

We identify 100 real-world scenarios across a broad spectrum of topics. Figure 2 illustrates the distribution of categories in SBE. The categories include:

- Business & Tech: Business & entrepreneurs, science & technology.
- Entertainment: Celebrity & pop culture, film, TV & video, gaming, music.
- Education: Learning & educational.
- News & Social Concern: News & social concern.

For each scenario, we pinpoint a central concept to be explained (explanandum) and crafted three distinct situations, each representing a potential audience with unique perspectives and concerns (desired feature). These audiences include foodies interested in exploring new and unique dishes, students navigating mental health challenges, and social media influencers looking to enhance their content engagement strategies.

To ensure the validity of our benchmarks, we 171 systematically develop a set of explanations for each scenario. To reflect the diverse needs and 173 backgrounds of the specified audiences, explana-174 tions are manually written by our research team. We ensure that each explanation not only addresses 176 the central concept but also resonates with the specific interests and concerns of the audience. This 178 approach provides us with a rich dataset of explana-179 tions that are both contextually relevant and varied 180 across different domains. Utilizing these carefully 181 crafted explanations as a benchmark, we evaluate 182 the performance of LLMs in generating situated NLEs.

Figure 2: The distribution of categories in SBE.

#### 4 Methods

#### 4.1 Rule-based prompting methods

#### **Base prompt**

Base:	{explanandum	}	because
-------	--------------	---	---------

**Specify the audience or the desired feature** Whereas previous work often limited prompting modifications to either audience or context-specific features, our approach combines both. This dual focus enables a more precise tailoring of explanations to the audience's needs and the contextual nuances of the explanandum:

Audience Specification (1A): Following is an
explanation towards {audience}. {explanan-
dum} because
Desired Feature Specification (1D): Follow-
ing is an explanation about {desired feature}.
{explanandum} because
Audience and Feature Specification (1AD):
Following is an explanation towards {audi-
ence}, about {desired feature}. {explanan-
dum} because

This innovation, denoted as 1AD, represents an extension beyond traditional single-focus prompts, aiming to enhance the relevance and clarity of the generated explanations.

# Adopt a persona **Do not simulate** (2F): Following is an explanation towards {audience}. {explanandum} because **Simulate the model as a helpful assistant** (2T): You are a helpful assistant explaining to {audience}. {explanandum} because

#### Elicit the NLE with complete sentences

241

275

276

Just use "because" (3F): Following is an explanation towards {audience}. {explanandum} because Use a complete sentence (3T): Following

is an explanation towards {audience}: {explanandum}.

By combining these three techniques, we construct a set of 12 distinct prompts (from 1A2F3F to 1D2T3T to 1AD2T3T).

To further enhance the adaptability and effectiveness of our prompting techniques, we introduce a set of new templates that have been empirically tested to optimize the models' performance. These templates are designed to integrate seamlessly with the refined prompting strategies, ensuring that each prompt not only cues the model for content generation but also aligns closely with requirements of the situated NLE task.

# 4.2 Meta prompt

216

217

218

219

229

230

To harness the capabilities of LLMs in generating contextually appropriate prompts, we employ a structured approach. This involves framing the prompt to explicitly include the intended audience and the specific features of interest, directing the model to tailor its response accordingly. Here is the format we propose for such prompts:

You are a helpful assistant helping me write a prompt. I want to write a prompt to generate an explanation about why {explanandum} to {audience}, about {desired feature}. Give me the prompt directly.

In our experiment, we tested prompts generated by GPT-3.5 on other models. Additionally, we evaluated each model's ability to generate its own prompts and then respond to them. This dual approach allowed us to not only assess the transferability of prompts across different models but also evaluate each model's capacity for self-driven contextual understanding and prompt formulation.

# 4.3 In-context Learning Prompt

In-context learning prompts serve as a powerful tool to enhance a model's ability to generate context-specific explanations. The suggested format for in-context learning prompts for audience1 in one situation is:

Q: Following is an explanation towards {audi-
ence2}, about {desired feature2}. {explanan-
dum} because
A: {explanation2}
Q: Following is an explanation towards {audi-
ence3}, about {desired feature3}. {explanan-
dum} because
A: {explanation3}
Q: Following is an explanation towards {audi-
ence1}, about {desired feature1}. {explanan-
dum} because
$\Delta \cdot$

1 .. .

1 ( 1'

The rationale for choosing the "1AD2F3F" template over others for the in-context learning prompt was guided by specific performance metrics observed in our initial testing phase. Specifically, the "1AD2F3F" template showed superior performance in terms of similarity scores and matching score when compared to other templates. The decision to focus on a single template, rather than attempting to replicate all possible templates in our demonstration setting, was based on practical constraints and the desire to optimize the demonstration's relevance and efficiency.

Overall, we collect 16 prompts and evaluate performance of several LLMs on a situated NLE task by each prompt.

# 5 Experiment setup

# 5.1 LLM explainers

We use 5 LLMs, including GPT-3.5-turbo (Ouyang et al., 2022), Pythia-2.8B (Biderman et al., 2023), LLaMa2-7B, LLaMa2-13B-chat (Touvron et al., 2023), and Yi-34B (AI et al., 2024), to generate situated NLEs.

# 5.2 Evaluation

In our experiments, we focus on two key metrics: similarity score and matching score. The similarity score measures the semantic similarity between the generated explanation and the desired explanation for a given situation. Matching score evaluates the overall suitability of the generated explanation to the given situation.

**Similarity score** To measure the similarity between two sentences, we employ a sentence embedding model, Sentence-BERT (SBERT) (Reimers and Gurevych, 2019a). Specifically, we use the all-MiniLM-L6-v2 model from the sentencetransformers library (Reimers and Gurevych,

277

307

309

312

313

314

315

316

297

296

2019b). The similarity between the two sentences is then computed as the cosine similarity between their embeddings. The score ranges from -1 to 1, with higher values indicating greater semantic similarity between sentences.

A higher similarity score indicates an LLMgenerated explanation is more approximate to the human-annotated explanation in SBE. However, how ought one evaluate whether an LLM-generated explanation is suitable for the audience in the situation?

Matching Score Within our evaluative framework, we adopt a scoring methodology predicated on the cross-entropy loss function to quantify the congruence between explanations generated by the LLM and the target explanations. The formula  $\sum_{c=1}^{N} y_c \log(p_c)$  delineates the computation of loss for a multi-class classification task, where N signifies the number of classes. Herein, the loss aggregates the weighted negative logarithms of the predicted probabilities  $p_c$  across classes c, with the weighting provided by the actual class indicators  $y_c$ .

For the purpose of our experiment, we designate N = 3 to align with the triad of situational contexts within a singular scenario. Let c denote the situational index, and j represent the index for LLM-generated explanations. As we have 3 explanations generated by LLMs,  $j \in [1,3]$ . Corresponding to each situation c, we associate the expert-annotated explanation  $h_c$ , and for each LLM response j, the model-generated explanation  $e_j$ . We calculate the similarity between  $h_c$  and  $e_i$  via the metric  $sim(h_c, e_i)$ , with higher metric values indicating increased similarity. These similarity metrics are treated as unnormalized log probabilities (logits), to which we apply a softmax transformation for the derivation of probability values:

$$p_{cj} = \frac{\exp(\operatorname{sim}(h_c, e_j))}{\sum_{c=1}^{3} \exp(\operatorname{sim}(h_c, e_k))}$$

Subsequently, we impose the cross-entropy loss on the probabilities  $p_{cj}$  to yield the matching score:

$$\operatorname{Matching}_{j} = -\sum_{c=1}^{3} y_{c} \log(p_{cj})$$

In this context,  $y_c$  is assigned a value of 1 when 317 the expert-annotated explanation  $h_c$  corresponds 318 with the LLM-generated explanation  $e_i$  (i.e., when 319 c = j), signifying a perfect match. In contrast,  $y_c$ 

assumes a value of 0 for non-matching explanations. With cross-entropy loss and our 3-situationdesigned dataset, Matching, in the equation quantitatively evaluate whether the LLM-generated explanation matches to the situation. Moreover, the cross-entropy loss Matching $_i$  is minimized when the LLM-generated explanation matches the situation. Compared with the similarity score, the matching score enables a quantitative assessment of the LLM's explanation adequacy.

Ultimately, the similarity score evaluates the degree to which explanations generated by the LLM align with human-annotated references, while the matching score quantifies the appropriateness of these explanations in their specific situational contexts.

#### 6 Results

Our results demonstrate several key findings regarding the efficacy of different prompting techniques in generating situated NLEs. Specific results are provided in the appendix; Figure 5, 6.

# 6.1 How do prompt techniques matter?

Figure 3 shows the performance of each prompt techniques. Similarity score and matching score of 1A in the figure is the average score of explanations generated by prompt 1A2F3F, 1A2T3F, 1A2F3T, 1A2T3T and 7 LLMs(GPT-4-turbo, Gemini-pro, GPT-3.5-turbo, Pythia-2.8B, LLaMa2-7B, LLaMa2-13B-chat, and Yi-34B).

Specify the audience or the desired feature Specifying both the audience and the desired feature(1AD) can lead LLMs to generate more suitable explanations comparing with only specify the audience(1A) or only specify the desired feature(1D). The technique specifying both audience and desired feature (1AD) yielded the best results, with an average similarity score of 0.634 and a matching score of 1.021, indicating that providing comprehensive contextual information significantly enhances model performance. Comparatively, specifying either the desire feature (1D) performs slightly better than specifying the desired feature (1A)(average similarity scores of 0.602 and 0.599, respectively, and matching scores of 1.040 and 1.046). This suggests that while each element alone provides some contextual grounding, their combination is more potent in guiding the model to generate relevant and precise explanations. Thus, we recommend to

Figure 3: Average similarity and matching scores for all prompt techniques. 'M-GPT' refers to the use of GPT-3.5turbo to generate prompts for situated NLE. 'Meta' refers to using the response model itself to generate prompts and respond to those. Note: A decrease in the matching score correlates with an enhancement in model performance on situated NLE tasks.

specify both the audience and the desired feature for a situated explanation.

Adopt a persona The results show that the do not 371 simulate the model as a helpful assistant (2F) approach yields a higher similarity score (0.635) compared to simulating the model as a helpful assistant 374 (2T) (0.590), indicating that explanations generated 375 without the persona are closer to human-annotated explanations. However, the matching score for 377 2T (1.034) is slightly better than for 2F (1.038), suggesting a marginally better alignment with the situational context when a persona is adopted. Despite this, the performance difference in matching scores is minimal, indicating that adding "You are a helpful assistant" to prompts for situated NLE tasks does not significantly aid the model's inferencing capability. Therefore, employing a persona in prompts is optional and may not be necessary for effective situated NLE generation. 387

Elicit the NLE with complete sentences The results highlight that use because (3F) method 389 achieves a superior similarity score (0.6361) compared to use a complete sentence (3T) (0.5880), demonstrating that incorporating "because" in prompts helps the language model generate explanations that are significantly closer to those in SBE. 394 Although 3T achieves a marginally better matching score (1.0289) than 3F (1.0427), this improvement is not substantial. Given the clearer advantage in similarity scores with 3F, we recommend using "because" in prompts for situated NLE tasks to more 399 effectively align the generated explanations with 400 the human-annotated standards. 401

Meta prompt In our exploration of meta prompts, we observed that these did not perform as well as those generated through the 1AD method. A notable issue with meta prompts is their tendency to include additional, often unnecessary specifications that may not align with the situational needs. For example, meta prompts including "Discuss the potential consequences of this problem and the importance of addressing it" introduce requirements that might not be relevant for the user. While maintaining fairness in our experimental evaluations, such specifics included in meta prompts led to their underperformance. This suggests that despite the innovative approach of using meta prompts, the traditional 1AD method remains more effective for generating situated natural language explanations aligned with the specific user contexts.

432

433

434

**In-context learning prompt** The performance of in-context learning prompts with regard to similarity scores is exemplary, demonstrating a state-ofthe-art capability to replicate human-annotated explanations. Nonetheless, the performance in matching scores suggests that these prompts may not effectively aid the model in comprehending the situational context. This indicates a potential area for further refinement to enhance the model's situational awareness and its ability to generate contextually appropriate responses.

#### 6.2 How do different LLMs perform?

As Figure 4 shows, the performance varies by LLM.

Why are GPT-4 and Gemini-Pro worse thanGPT-3.5?Why are GPT-4 and Gemini-Pro con-

Figure 4: Average similarity and matching scores for all LLMs: 'P-2.8' represents Pythia-2.8B, 'L-7' stands for LLaMa-7B, 'L-13' is LLaMa-13B, and 'Y-34' indicates Yi-34B. Note: A decrease in the matching score correlates with an enhancement in model performance on situated NLE tasks.

	Similarity	Matching
Avg.	0.625	1.042
ICL	0.766	1.031

Table 2: Performance of the in-context learning prompt technique compared with the average performance on all prompt techniques.

sidered worse than GPT-3.5 in our evaluation? The 435 explanations generated by GPT-4 and Gemini-Pro 436 tend to be overly detailed, usually presented in a 437 list format with up to seven points. (Appendix; 438 Tabel 4, 5) This makes their explanations not only 439 too lengthy but also excessively specific. For in-440 stance, the average length of a human-annotated 441 explanation is about 29.5 words, while the average 442 for GPT-4-generated explanations is 421.9 words, 443 and for Gemini-Pro, it's 198.7 words. In contrast, 444 GPT-3.5-generated explanations have an average 445 length of 137.6 words. Consequently, the perfor-446 mance of GPT-4 and Gemini-Pro is deemed inferior 447 under our evaluation metrics, as their lengthy and 448 overly specific outputs do not align well with our 449 human-annotated explanations. 450

451 Commercial vs. open-source LLMs In our comparisons, models such as GPT-4, GPT-3.5, and
453 Gemini-Pro, which are developed with significant
454 commercial backing, consistently outperform their
455 open-source counterparts. These commercially456 developed models excel in generating more suit457 able, contextually appropriate explanations.

Variations among open-source LLMs When examining open-source language models, particularly those within the same family or architecture, we observe that the performance differences are not as stark in terms of matching scores. However, in terms of similarity scores, there is a clear hierarchy: Pythia-2.8B < Yi-34B < LlaMa-7B < LlaMa-13B. Although larger models generally show enhanced capabilities, suggesting that size contributes to model effectiveness, it is not the only factor influencing performance. Notably, LlaMa-7B and LlaMa-13B outperforms the larger Yi-34B model, indicating that factors beyond mere scale, such as model design, training protocol, or data quality, also play critical roles in determining a model's effectiveness. One the other hand, LlaMa-13B achieves better performance than LlaMa-13B. This result reinforces the idea that within a consistent architectural and training framework, larger models tend to demonstrate superior capabilities.

#### 7 Discussion

**Variance in Scenario Performance** Our analysis reveals an interesting pattern in the variance of model outputs across different types of scenarios. Contrary to expectations, we find more variance among model outputs in scenarios related to daily life, which include a wide range of everyday activities and social interactions. This greater variance could be attributed to the inherent complexity and variability of such situations in daily life, which are less standardized and thus more challenging to simulate accurately. By contrast, scenarios in-

volving specialized domains such as technology, 490 politics, and health exhibited less variance among 491 the outputs from different models. These areas 492 often involve more standardized and well-defined 493 concepts and terminologies, which are easier for 494 models to inference. As a result, language models 495 appear to handle these topics with greater consis-496 tency, possibly due to the clearer and more uniform 497 contexts provided in such scenarios. 498

# 8 Conclusion

499

Based on the task of situated natural language explanations, this paper introduces SBE, a novel 501 benchmarking dataset including audiences with de-502 sired features in specific situations. We use quan-503 titative methods to evaluate different prompts and 505 different LLMs and we rigorously evaluate the effectiveness of various prompting techniques and the performance of diverse large language models using quantitative methods. Our findings not only 508 509 demonstrate the strengths and limitations of current approaches but also prepare future research to en-510 hance the adaptability and precision of automated 511 explanations tailored to distinct user contexts.

# 513 Limitations

While our study marks a significant advancement in the field of situated natural language explanations 515 (NLEs) by introducing the SBE and demonstrating 516 the adaptability of language models to various con-517 texts, it inherently simplifies the complex reality of 518 potential real-life situations. SBE, designed with 519 three specific contexts per explanandum, offers a 520 quantitative approach to evaluating model perfor-521 mance but does not encompass the near-infinite 522 variety of scenarios shaped by diverse audiences and their unique needs. Consequently, the results, though robust within the defined parameters, may 525 not fully capture model effectiveness in more dy-526 namically varied or extensively nuanced real-world applications. Future research should focus on ex-528 panding the dataset to cover a broader spectrum of situations among different backgrounds and biases. Moreover, refining the models to enhance their adaptability to the multifaceted nature of real-532 life contexts should be considered. 533

# 34 Ethics Statement

In our research, we simulate hypothetical user situations to generate tailored explanations, which
might, on LLM agents, trigger the use of personal

data if not deployed properly. The implication of 538 deploying similar technology in real-world settings 539 raises significant privacy concerns. Although our 540 study does not entail these risks due to the nature of 541 our data, future LLM agents must consider imple-542 menting stringent data protection measures. These 543 should include robust anonymization techniques, 544 minimal data retention policies, and adherence to 545 privacy regulations to safeguard individual data 546 rights. Additionally, as LLM-generated explana-547 tions become more convincing, they could be adver-548 sarially helpful (Ajwani et al., 2024). Approaches 549 to defend adversarial helpfulness include asking 550 the explainers to present information from multi-551 ple perspectives, which is relevant to adaptation. 552 Last but not least, it is crucial to clarify that the 553 explanations generated by our models are algorith-554 mic outputs and do not reflect personal beliefs or 555 empirical truths. 556

User instruction	Following is an explanation towards students, about engaging and adaptive learning tools tailored to individual preferences. Educational technology can be meaningful because					
GPT-4 generated explanation	Engaging and adaptive learning tools tailored to individual preferences are meaningful in educational technology because they help create personalized learning experiences that meet the unique needs and strengths of each student. Here are several reasons why these tools are particularly effective:					
	• <b>Personalization</b> : Adaptive learning technologies can adjust the content, pace, and difficulty based on individual learning preferences and performance. This means students can learn in a way that is best suited to their own style and pace, which can help to foster deeper understanding and retention of knowledge.					
	• <b>Increased Engagement</b> : Engaging learning tools are designed to capture and maintain students' interest through interactive elements such as games, quizzes, and interactive simulations. When students are engaged, they are more likely to invest time and effort in their learning, which can lead to better outcomest the students are engaged.					
	• Accessibility and Inclusivity: Adaptive learning tools can also provide support for learners with diverse needs, including those with disabilities. For example, text can be converted to speech for students with visual impairments, or lessons can be structured in different ways to cater to various learning disabilities. This inclusivity ensures all students have an equal opportunity to learn and succeed.					
	• <b>Immediate Feedback</b> : These tools often provide immediate feedback, which is crucial for learning. Students can understand what they're doing right and where they need improvement. This immediate response helps them to adjust their strategies and efforts in real time, promoting a more efficient learning process.					
	• <b>Data-driven Insights</b> : Adaptive tools often collect data on student performance, which can be analyzed to provide insights into learning habits, difficulties, and progression. This information can be invaluable for teachers and educators to further tailor learning experiences, provide targeted support, and even refine curriculum and instructional strategies.					
	• <b>Scalability</b> : Technology enables these personalized learning experiences to be scaled across large numbers of students without the same increase in resources that would be necessary if done manually by educators. This is particularly valuable in under-resourced or rural areas.					
	• <b>Skill Preparation</b> : Modern educational tools prepare students for the technological world they will enter into after their education. By using tech-based tools in their learning process, students become proficient in digital literacy, a critical skill for almost all career paths in the modern workforce.					

User instruction	Following is an explanation towards students, about engaging and adaptive learning tools tailored to individual preferences. Educational technology can be meaningful because					
Gemini-Pro generated explanation	<ul> <li>Engaging and Adaptive Learning Tools Tailored to Individual Preferences</li> <li>Educational technology can be transformative when it provides students with personalized learning experiences tailored to their unique needs and preferences. By using engaging and adaptive tools, educators can create environments where students can thrive and achieve their full potential.</li> <li>Engaging Tools:</li> </ul>					
	• Interactive Simulations and Games: These provide immersive experiences that allow students to explore complex concepts in a fun and interactive way.					
	• Virtual Reality (VR) Environments: VR headsets transport students to virtual worlds, allowing them to experience real-life scenarios and conduct experiments in a safe and controlled environment.					
	• Social Collaboration Tools: Platforms that allow students to connect with peers, ask questions, and engage in group projects foster collaboration and enhance learning.					
	Adaptive Tools:					
	• Adaptive Learning Systems: These adjust course content and assessments to match the individual student's learning pace, skill level, and learning style.					
	• <b>Intelligent Tutoring Systems (ITS):</b> ITSs provide personalized guidance and feedback to students, helping them identify areas for improvement and build on their strengths.					
	• AI-Powered Language Tools: These tools assist students with writing and reading, providing real-time feedback on grammar, vocabulary, and comprehension.					
	Tailored to Individual Preferences:         These tools can be tailored to cater to different learning preferences:					
	• Visual Learners: Simulations, VR environments, and interactive videos engage visual learners.					
	• Auditory Learners: Audio-based lessons, podcasts, and recorded lectures cater to auditory learners.					
	• <b>Kinesthetic Learners:</b> Hands-on activities, simulations, and collaborative projects provide opportunities for kinesthetic learners.					
	Meaningfulness of Educational Technology: By providing students with engaging and adaptive learning tools tailored to their individual preferences, educa- tional technology can make learning:					
	• Personalized: Content and assessments are tailored to meet the specific needs of each student.					
	• Motivating: Interactive and engaging tools keep students interested and motivated to learn.					
	• Effective: Adaptive systems track student progress and provide personalized feedback to enhance learning outcomes.					
	• Equitable: Technology provides all students with equal access to high-quality learning experiences, regardless of their background or learning style.
