ABSTRACT

011 Formal models are essential to specifying large, complex computer systems and
012 verifying their correctness, but are notoriously expensive to write and maintain.
013 Recent advances in generative AI show promise in generating certain forms of
014 specifications. However, existing work mostly targets small code, not complete
015 systems. It is unclear whether AI can deal with realistic system artifacts, as this
016 requires abstracting their complex behavioral properties into formal models. We
017 present SYSMOBENCH, a benchmark that evaluates AI’s ability to formally model
018 large, complex systems. We focus on concurrent and distributed systems, which
019 are keystones of today’s critical computing infrastructures, encompassing operating
020 systems and cloud infrastructure. We use TLA⁺, the *de facto* specification
021 language for concurrent and distributed systems, though the benchmark can be ex-
022 tended to other specification languages. We address the primary challenge of eval-
023 uating AI-generated models by automating metrics like syntactic and runtime cor-
024 rectness, conformance to system code, and invariant correctness. SYSMOBENCH
025 currently includes eleven diverse system artifacts: the Raft implementation of Etcd
026 and Redis, [the leader election of ZooKeeper](#), the Spinlock, Mutex, and [Ringbuffer](#)
027 in Asterinas OS, etc., with more being added. SYSMOBENCH enables us to un-
028 derstand the capabilities and limitations of today’s LLMs and agents, putting tools
029 in this area on a firm footing and opening up promising new research directions.
030

1 INTRODUCTION

031 Formal models are essential to specifying computer systems and reasoning about their correctness.
032 They provide a mathematical foundation to document and verify the *design* of complex systems,
033 such as distributed protocols and concurrent algorithms (Lamport, 2002; Tasiran et al., 2003; New-
034 combe et al., 2015; Hackett et al., 2023b). Recently, formal models are used to describe system
035 *implementations*—system code that runs on user devices and in production environments. Such
036 models, which we refer to as *system models*, enable verification of system code via comprehensive
037 testing and model checking (Bornholt et al., 2021; Tang et al., 2024; Ouyang et al., 2025; Tang et al.,
038 2025). For example, system models of Apache ZooKeeper (a distributed coordination system) were
039 used to detect deep bugs that violate system safety and verify their fixes (Ouyang et al., 2025).
040

041 However, system models are notoriously expensive to write and maintain. Different from protocols
042 and algorithms, system code contains low-level details, is more complex, and constantly evolves.
043 Hence, synthesis of system models is an open challenge (e.g., TLAi+ Challenge (2025)).

044 Recent advances in generative AI, represented by large language models (LLMs) and agentic tech-
045 niques, show promise in generating function-level specifications, in the form of pre- and post-
046 conditions (Rego et al., 2025; Cao et al., 2025; Xie et al., 2025; Chakraborty et al., 2025; Ma et al.,
047 2025). It indicates that AI techniques can capture certain behaviors of software programs. However,
048 it is unclear whether AI could effectively model a complex system, which requires altogether dif-
049 ferent capabilities than the synthesis of pre- and post-conditions of a function. Modeling a system
050 requires the AI to understand the system design (e.g., the underlying protocols and algorithms), rea-
051 soning about safety and liveness under unexpected faults and external events, and abstracting system
052 behavior into an executable program. It is unclear to what extent AI has such capabilities.
053

In this paper, we present SYSMOBENCH, a benchmark to evaluate AI’s ability to formally model
complex systems. We target all forms of generative AI, including LLMs and agentic techniques.

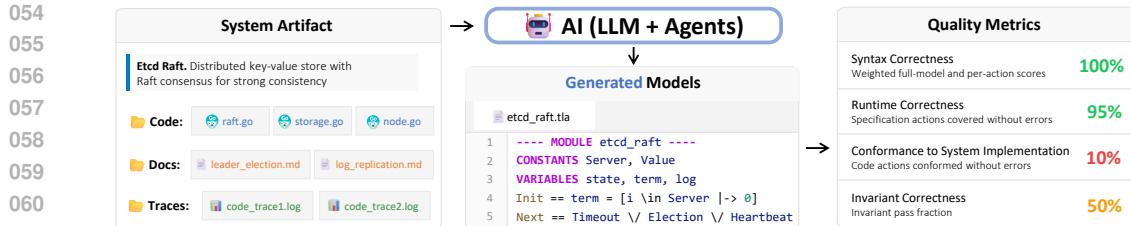

Figure 1: **SYSMOBENCH** sources its tasks from real-world systems (e.g., EtcD Raft in the figure). It automatically evaluates the system models in TLA^+ generated by AI with different metrics.

We focus on *concurrent and distributed systems*, which are especially difficult to model. They also underpin today’s critical computing infrastructure, which includes operating systems and cloud computing. We focus on TLA^+ , the *de facto* formal specification language for concurrent and distributed systems (§2). **SYSMOBENCH** can be easily extended to support other specification languages such as Alloy (Jackson, 2012), PAT (Sun et al., 2009), P (Desai et al., 2013), and SPIN (Holzmann, 1997). We have added the support for Alloy and PAT (see Appendix B).

The key challenge of **SYSMOBENCH** is to *automatically* evaluate AI-generated models—how can we tell if a system model is of high quality? We did not find any directly applicable metrics in use by existing work on TLA^+ specification generation. For example, Cao et al. (2025) only check if the generated TLA^+ specification can be run by the TLC model checker (Yu et al., 1999). But, successfully running TLC is not an indicator of whether the model correctly describes the system. One approach is to evaluate AI-generated pre-/post-conditions (Rego et al., 2025; Ma et al., 2024) against human-written reference specifications. However, such a comparison can be brittle, and real-world systems rarely have such low-level specifications. Writing a system model remains a highly challenging expert task that requires months *to years* of effort.

A key contribution of our benchmark is quality metrics that can be *automatically* checked. These metrics reflect the fundamental requirements of a formal system model for use cases like formal verification (Lamport, 2002) and model-driven testing (Clarke et al., 2018).

- **Syntax correctness.** We statically check whether the generated system model uses valid TLA^+ syntax using the SANY Syntactic Analyzer.
- **Runtime correctness.** We check how much of the generated TLA^+ can be executed using the TLC model checker (Yu et al., 1999), which is a proxy for logical self-consistency.
- **Conformance.** We measure whether the model conforms to the system implementation via trace validation (Cirstea et al., 2024; Tang et al., 2025; Hackett & Beschastnikh, 2025).
- **Invariant correctness.** We model-check the system model against system-specific invariants that reflect the system’s safety and liveness properties.

SYSMOBENCH currently includes eleven real-world artifacts, including distributed systems like EtcD, Redis, and ZooKeeper, and concurrent systems like spinlock, mutex, and ringbuffer from Asterinas OS. We also include system artifacts synthesized by PGo (Hackett et al., 2023a) to evaluate AI’s ability to comprehend *generated* system code. More system artifacts are actively being added.

SYSMOBENCH enables us to understand the capabilities and limitations of AI in *using TLA^+* to model real-world systems by evaluating different agent designs with various AI models. State-of-the-art LLMs show good performance in modeling small system artifacts such as a spinlock implementation. On the other hand, these LLMs show limited ability in comprehending and abstracting large, complex systems such as a Raft implementation (Ongaro & Ousterhout, 2014). Overall, we believe that **SYSMOBENCH** can spur innovative AI approaches in the context of formal system models, similar to the role of SWE-bench (Jimenez et al., 2024) in software engineering.

Here is a snapshot of **SYSMOBENCH**: <https://anonymous.4open.science/r/SysMoBench-BA9F/>.

2 BACKGROUND

SYSMOBENCH focuses on formal models written in TLA^+ (Lamport, 2002), which is the *de facto* formal specification language for modeling distributed and concurrent systems in practice. The

Figure 2: Simplified code that implements a spinlock in Asterinas (left) and an AI-generated TLA⁺ model (right). A spinlock represents the simplest system in SYSMOBENCH.

choice of TLA⁺ is made from a practical standpoint, not a language standpoint (SYSMOBENCH supports other specification languages; Appendix B). TLA⁺ is widely used by software companies like Amazon, Microsoft, Nvidia, Google, Oracle, etc (see TLA+ Foundation (2025)) to check and verify critical infrastructure systems such as distributed consensus systems (e.g., Etcd and ZooKeeper), confidential consortium frameworks (Howard et al., 2025), databases (e.g., CosmosDB and MongoDB), OS kernel synchronization (Tang et al., 2025), and cache coherence (Beers, 2008).

A TLA⁺ model specifies system behaviors as a collection of state variables, an initial predicate that defines their initial values, a next-state relation that determines state transitions, and temporal properties that specify correctness requirements. The next-state relation is expressed as multiple actions, each describing an atomic state update of all variables. TLA⁺ is built upon the Temporal Logic of Actions (TLA), which *includes and extends* standard linear temporal logic (LTL) (Pnueli, 1977), providing a rigorous mathematical foundation for reasoning about system behavior over time. TLA⁺ models can be verified using explicit-state model checking via TLC (Yu et al., 1999), symbolic model checking via Apalache (Konnov et al., 2019), and deductive verification via the TLA⁺ Proof System (Chaudhuri et al., 2010). In SYSMOBENCH, we primarily use TLC, the most widely used TLA⁺ tool that systematically explores all reachable states of a system model to ensure that properties hold over the entire state space. These characteristics make TLA⁺ particularly well-suited for modeling complex concurrent and distributed systems.

Figure 2 shows simplified code that implements a spinlock in the Asterinas operating system (Peng et al., 2025) and the corresponding TLA⁺ model that describes the code. The TLA⁺ model is generated by the AI agent we evaluate in §5. The model defines constants such as Threads (line 1) and system-state variables such as lock_state and pc (line 2). The initial state Init (line 3) assigns initial values to all variables. Three actions are defined (lines 5–19)—StartLock, Acquire, and Unlock—corresponding to the code logic, where Acquire combines the logic of acquire_lock and try_acquire_lock. Each action is enabled by certain conditions, e.g., StartLock is enabled when a thread’s pc is “idle”; it then assigns next-state values to all variables.

To model the spinlock implementation, the AI must first understand the behavior of each function. Next, it must decide how to represent the system. This involves introducing variables, such as auxiliary ones like pc, and defining atomic actions that preserve concurrency semantics. Finally, the AI must specify correctness properties. For example, mutual exclusion (line 22) requires that in every state, at most one thread can be in the “locked” state.

Note that SYSMOBENCH concerns formal models of system implementations, or *system specifications* in the TLA⁺ and formal method literature. As a specification, a system model enables verification of system code, but does not necessarily capture requirements of the design (Stoica et al., 2024). SYSMOBENCH does not target other forms of specifications, such as formal proofs (Chen et al., 2025) or function-level pre- and post-conditions (Ma et al., 2025).

162 3 SYSMOBENCH
163164 SYSMOBENCH is a benchmark that uses real-world distributed and concurrent system artifacts to
165 evaluate AI’s ability to formally model systems. Table 1 lists the systems that have been integrated
166 in SYSMOBENCH; we are actively adding more system artifacts (§3.3).
167168 Table 1: System artifacts that have been integrated in the SYSMOBENCH; “TLA⁺ LoC” refers to
169 the AI-generated TLA⁺ models presented in our evaluation results (§5).

182 3.1 TASK FORMULATION
183184 A SYSMOBENCH task is to generate a system model for a given system artifact (Table 1). SYS-
185 MOBENCH does not concern how the system model is generated. It can be generated by prompting
186 LLMs directly, with few-shot learning, or with agentic techniques that invoke external tools (we
187 evaluate both in §5). Since system artifacts in SYSMOBENCH are real-world system projects, one
188 can feed various data sources to the LLMs/agents, such as source code, documents, and runtime
189 traces. The task mirrors real-world modeling workflows of human engineers.
190191 Each task specifies the granularities at which to model the target system’s essential behavioral prop-
192 erties and state transitions. The required level of granularity is defined based on target use cases; our
193 current use case is model-checking based system verification—we require the same level of detail
194 as in prior work on verification and bug finding. The model must include core actions that interact
195 with other components, while excluding implementation details unrelated to system behavior. We
196 evaluate behavioral conformance rather than structural equivalence, allowing fine-grained model-
197 ing of core actions as long as they preserve semantic obligations needed for verification. To make
198 requirements concrete, each task lists core actions that must be modeled and actions that should
199 be excluded. Take Spinlock as an example (Figure 2): the requirements are specified as follows:
200200 **Mandatory core actions that must be modeled:**201

- 202 • The model must specify lock() and unlock() actions.
- 203 • Atomic compare.exchange operation on the lock variable.
- 204 • Spinning when the lock is contended.

204 **Actions that should be excluded from the model:**205

- 206 • RAI guard implementation details.
- 207 • Non-core details (e.g., debug formatting and trait implementation).

208 Besides, the task also requires generating a TLC configuration as a part of the model.
209210 3.2 METRICS AND THEIR MEASUREMENT
211212 Key contributions of SYSMOBENCH are to (1) define metrics that can fairly measure the quality of
213 AI-generated TLA⁺ models, and (2) design practical techniques to automate metric measurements.
214 SYSMOBENCH does not rely on human evaluation which is slow and hard to scale, especially for
215 complex real-world systems. We do not consider LLM-as-a-judge approaches, as we find these
unreliable and difficult to interpret.

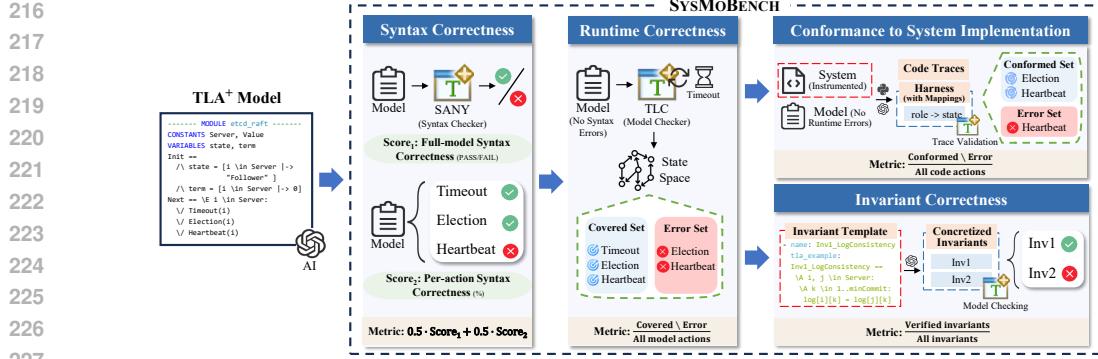

Figure 3: Metrics and evaluation workflow of SysMoBench. The red dashed boxes denote inputs provided by the system artifact: instrumented system for code traces and required invariants.

SYSMOBENCH includes four metrics that evaluate a TLA⁺ model on syntax (§3.2.1), runtime correctness (§3.2.2), conformance to system code (§3.2.3), and invariant correctness (§3.2.4). The metrics are not independent, e.g., a model with syntax errors cannot be evaluated for other metrics. An executable model is evaluated for both conformance and invariant correctness. We design *partial scoring* schemes for every metric and normalize results to percentage values, making them easy to interpret. Figure 3 illustrates the metrics and the evaluation workflow.

3.2.1 SYNTAX CORRECTNESS

SYSMOBENCH uses the TLA⁺ SANY Syntactic Analyzer (Lamport, 2002) to check the syntax of the TLA⁺ models against TLA⁺ grammar rules, operator usage, module structure, etc. Note that SANY checks the entire model specification. If the model specification passes the SANY checks, it earns a full score. However, many AI-generated models fail the SANY check; therefore, we need fine-grained analysis for partial scoring.

SYSMOBENCH offers per-action analysis for partial scoring by checking how many generated actions are erroneous (and failed SANY). It encapsulates each action in the model into a per-action model by adding necessary dependencies (e.g., constant declarations, variable definitions, etc.). It then uses SANY to check the **syntax of per-action model (only syntax correction is concerned in this step; no equivalence check)**. A partial score S represents the percentage of correct actions n_c among the total actions n_t , i.e., $S = \frac{n_c}{n_t}$. Here, n_c is determined by running SANY on each per-action module and counting those that pass without syntax errors, while n_t is obtained by counting all action definitions in the original model. Note that the per-action checks do not account for inter-action dependencies: a model that passes all the per-action checks can still fail. We use a weighted scoring scheme that gives equal weights to per-action correctness and inter-action correctness. A model that passes the overall SANY check earns 100%, while only passing all per-action checks earns 50%. Only system models with 100% syntax scores will be evaluated for other metrics, because models with syntax errors cannot be compiled or executed (which is required by other metrics).

3.2.2 RUNTIME CORRECTNESS

For a syntactically correct system model, SysMoBench next evaluates if the model can be executed correctly. To do so, SysMoBench performs bounded model checking and simulation using TLC, and then observes covered actions and runtime errors (if any) **by parsing TLC's coverage report and error output**. This model checking and simulation explores the state space without any invariant checking (see §3.2.4). During this state space exploration, SysMoBench records all covered actions and the actions with runtime errors.

We define a metric M_r that represents the coverage of actions without runtime errors: $M_r = \frac{n_r}{n_t}$, where n_r is the number of covered actions that did not report errors during state exploration, and n_t is the total number of actions in the model.

Models with no runtime errors can then be executed to explore state space. Only such models are evaluated for conformance and invariant correctness.

270 3.2.3 CONFORMANCE TO SYSTEM IMPLEMENTATION
271

272 For an executable model, **SYSMOBENCH** evaluates its conformance to the behavior of the system
273 implementation using trace validation (Cirstea et al., 2024). Trace validation checks whether a
274 trace of the system execution corresponds to a path in the model’s state space. **SYSMOBENCH**
275 supports trace validation mechanisms used by different systems (Tang et al., 2025; Cirstea et al.,
276 2024; Hackett & Beschastnikh, 2025).

277 Specifically, to collect execution traces, system code is instrumented with logging statements. The
278 instrumentation granularity matches the granularity requirements of the task. If the AI-generated
279 model is coarser than the trace logs, conformance checking could fail; otherwise, we use missing-
280 event inference techniques (Tang et al., 2025) to account for uninstrumented actions.

281 The key challenge of automatic conformance checking of any AI-generated models is to correctly
282 map the elements in the model to elements in the system execution log. This is because AI will
283 often use names that differ from those in system code. We solve this problem by using a coding
284 LLM (e.g., Claude-Sonnet-4) to (1) extract constants, variables, and actions from the input model
285 and (2) map them to the corresponding elements specified in the task requirement (§3.1).

286 The use of LLMs for automatic mapping of elements in the model and code may raise reliability
287 concerns. In our experience, state-of-the-art LLMs accomplish the mapping task reliably (§4). This
288 is because (1) the mapping task is simple and well-defined; (2) the generated models are derived
289 from the system artifacts and thus largely follow the naming conventions of the system; and, (3)
290 our trace validation technique (Tang et al., 2025) can tolerate a certain level of missing variables or
291 actions though we have not found such cases so far. A similar use of LLMs for mapping is adopted
292 in TLAi+Bench (2025) (discussed in §6).

293 During trace validation across all traces, **SYSMOBENCH** keeps track of code actions that are covered
294 and those code actions that trigger errors. Specifically, **SYSMOBENCH** feeds the trace to TLC
295 along with the model, and records whether TLC successfully validates the trace. If validation fails,
296 **SYSMOBENCH** identifies where the mismatch occurred by analyzing TLC’s trace validation output.
297 To measure conformance, we define M_c as the coverage of code actions without conformance errors:
298 $M_c = \frac{n_c}{n_t}$, where n_c is the number of code actions that were covered during validation with no errors,
299 and n_t is the total number of actions in the instrumented code. We use instrumented code actions
300 instead of model actions because this provides a stable, implementation-grounded granularity that is
301 consistent across different AI-generated models.

302 3.2.4 INVARIANT CORRECTNESS

303 **SYSMOBENCH** also evaluates whether AI-generated models always satisfy invariants that describe
304 the expected safety and liveness properties of the system. In principle, if a system model fully
305 conforms to code, violations of these invariants would indicate bugs in system code; in practice,
306 few AI-generated models achieved fine-grained conformance. Nevertheless, AI-generated models
307 have demonstrated practical utility by successfully reproducing known bugs from previous system
308 versions (Appendix C.2). Table 2 lists the invariants for the spinlock code in Figure 2. These
309 invariants are part of the benchmark defined by the task (§3.3).

310 311 Table 2: Example spinlock invariants

Invariants	Description	Type
Mutual exclusion	At most one process can be in the critical section at any time	Safety
Lock consistency	The lock state accurately reflects critical section occupancy	Safety
No deadlock	Not all threads can be stuck spinning simultaneously	Safety
Guard lifecycle	Every thread eventually releases the lock it acquires	Liveness
Eventual release	The system eventually reaches a state where all threads are idle	Liveness

312 313 314 315 316 317 318 319 320 321 322 323 324 **SYSMOBENCH** addresses a similar challenge as in §3.2.3: it needs to automatically map the actions,
325 variables, and data structures in the system model to those expressed in the invariants. For this,
326 the invariants in **SYSMOBENCH** are templates that contain a description of the property, formal
327 definitions, and example TLA⁺ invariants. We then use an LLM to translate these templates into
328 model-specific invariants that can be checked against the system model. For example, the following
329 template defines the mutual exclusion invariant in Table 2:

```

324
325   - name:"MutualExclusion"
326     type:"safety"
327     natural_language:"Only one thread can access a shared resource at a time"
328     formal_description:"No more than one thread in the critical section"
329     tla_example:MutualExclusion == Cardinality({t \in Threads:pc[t] = "in_cs"}) <= 1
330
331
332
333
334

```

SYSMOBENCH prompts the LLM with both the invariant template and the system model and asks it to concretize the template using the model. This mapping is highly structured: the output substitutes the template's variables and constants with those in the model. For example, the mutual exclusion invariant, $\text{Cardinality}(\{t \in \text{Threads}: \text{status}[t] = \text{"locked"}\}) \leq 1$, is a concretization of the template by replacing pc with status and in_cs with locked . We evaluate the reliability of this LLM-assisted concretization in §4.

The invariants are used by TLC during model checking, and SYSMOBENCH observes whether each invariant is violated. Specifically, for each invariant, SYSMOBENCH creates a separate model with that invariant and runs TLC independently. This allows SYSMOBENCH to record whether each invariant is violated. We define a metric M_i that represents the *fraction of invariants passed*, denoted as $M_i = \frac{n_i}{n_t}$, where n_i is the number of invariants that hold across the explored state space, and n_t is the total number of invariants defined for the model. Models with a higher M_i are of higher quality. When combined with runtime and conformance coverage metrics, a higher M_i increases confidence in the correctness of the input specification.

3.3 ADDING NEW SYSTEMS AND SPECIFICATION LANGUAGES TO SYSMOBENCH

SYSMOBENCH provides an extensible framework to add more real-world system artifacts. To add a new artifact to SYSMOBENCH, one needs to (1) prepare the system artifact (e.g., source code and documents); (2) create a new task that specifies the abstractions and components to model (§3.1); (3) develop invariant template (§3.2.4) that specifies correctness properties (safety and liveness); and (4) provide harness for trace validation by instrumenting system code. In our experience, the effort to add a new system artifact to SYSMOBENCH is manageable. For example, adding Etcd Raft took one SYSMOBENCH author four days; an Xline CURP contributor with no experience of SYSMOBENCH added the system to SYSMOBENCH in four days. Most of the effort is spent on instrumenting the system to collect execution logs for trace validation in order to measure conformance. Unlike other benchmarks (§6), SYSMOBENCH does not require writing reference models; in fact, we hope that some of the AI-generated models can eventually be adopted by real-world system projects.

SYSMOBENCH is extensible to formal specification languages other than TLA⁺. We extended SYSMOBENCH to support Alloy (Jackson, 2012) and PAT (Sun et al., 2009), demonstrating its generality. Details of these extensions and preliminary evaluation are presented in Appendix B. The results show that while our framework is extensible, TLA⁺ remains the practical choice and can benefit from AI-driven techniques (existing LLMs are less familiar with Alloy and PAT).

4 EVALUATION SETUP

To evaluate AI's system modeling abilities, we use three agents powered by LLMs.

- **Basic Modeling Agent.** This agent reflects the LLM's raw modeling abilities. The agent prompts an LLM with the source code of the system and the task requirement (§3.1). The detailed prompts are documented in Appendix G.
- **Code Translation Agent.** This agent uses an LLM to *translate* system code into an equivalent TLA⁺ form. The agent translates code statement by statement (from the source language to TLA⁺), and then organizes the control flows of the translated statements into a TLA⁺ model. The agent reflects the capabilities of LLM-based code translation. We adopt the implementation of Specula (2025) as our code translation agent.
- **Trace Learning Agent.** This agent does not use code as input, but tries to learn the system model from system traces. It prompts LLMs with the traces to infer the system model (see Appendix H). This agent reflects the capability of automata learning (Biermann & Feldman, 1972) with LLMs.

We follow HumanEval (Chen et al., 2021) to run each agent five times and evaluate the best output model. The agents can enhance the model with feedback loops (three iterations are allowed) if the generated model cannot pass compilation or has runtime errors. No human intervention is allowed.

378 Table 3: Evaluation results of two AI agents on two representative system artifacts. ✓ and ✗ mark
 379 whether the model is evaluated in the next phase of measurements (see Figure 3).

(a) Asterinas Spinlock					
Agent	LLM	Syntax	Runtime	Conformance	Invariant
Basic Modeling	Claude-Sonnet-4	100.00% ✓	100.00% ✓	100.00%	100.00%
	GPT-5	100.00% ✓	100.00% ✓	80.00%	100.00%

	DeepSeek-R1	100.00% ✓	0.00% ✗	-	-

401
 402 We use four different LLMs to power the three agents: Claude-Sonnet-4 (20250514), GPT-5
 403 (20250807), Gemini-2.5-Pro (20250617), and DeepSeek-R1 (20250528). We run the SANY Syntactic
 404 Analyzer, TLC model checker, and system code (for conformance checking) on a server with
 405 dual AMD EPYC 7642 48-Core Processors and 256GB RAM running Ubuntu 22.04.

406 **Robustness of LLM-assisted Components.** SYSMOBENCH uses LLM-assisted techniques to map
 407 elements in an AI-generated TLA^+ model to those in the system logs (§3.2.3), and to concretize
 408 invariant templates (§3.2.4). We inspected the LLM-assisted mapping and concretization, and found
 409 the results to be correct. We also conducted an experiment using the “gold model” for Etcd Raft
 410 and Asterinas spinlock, which are known to be correct. We created 10 models (5 for each system)
 411 by changing the names of the variables and actions and tweaking the model’s granularity. The gold
 412 models achieve a perfect score on all metrics, empirically validating the quality of our metrics.

413 **Training Data Contamination.** One may be concerned about the fairness of SYSMOBENCH be-
 414 cause it uses open-source projects where the system code likely already appears in LLM training
 415 data. In fact, it is intended to have system code in LLM training data. The design mirrors how
 416 human engineers write formal models: they first learn system code before writing formal models.
 417 Our goal is to leverage LLMs to write effective TLA^+ models for important, safety-critical software
 418 systems, which requires LLMs to have internalized knowledge of these systems. Note that this is
 419 different from coding benchmarks in that we ask LLMs/agents to write existing code.

420 Second, few system artifacts in SYSMOBENCH have TLA^+ system models in their open-source
 421 repositories. The TLA^+ models of Asterinas Spinlock/Mutex/Rwmutex are never released. Redis
 422 Raft and Xline CURP do not have any TLA^+ models. Etcd Raft and PGo systems do have TLA^+
 423 models in the repositories. However, those models are for protocols, not for system code. Our goal
 424 is to use AI to write TLA^+ models for all important, safety-critical software systems in the wild.

425 5 RESULTS

426 We present evaluation results for the *basic modeling agent* and the *code translation agent* on Aster-
 427 inas Spinlock and Etcd Raft (Table 3). Appendix I.2 contains the complete results for all systems in
 428 SYSMOBENCH. We omit the results of the trace learning agent (which fails to pass runtime checks).

429 **Modeling Capability.** We focus on the results of the basic modeling agent. The basic modeling
 430 agent can generate high-quality TLA^+ models for Spinlock, which is among the simplest artifacts
 431 in SYSMOBENCH (Table 1), showing certain levels of modeling capability. However, for larger

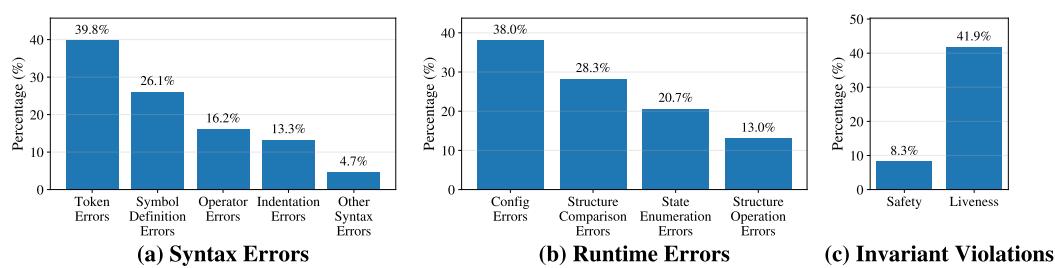

Figure 4: LLM error attribution regarding the SYSMOBENCH metrics in the basic modeling agent. The conformance metric is omitted as it has a single attribution.

and more complex systems such as the distributed protocol implementations, the basic modeling agent performs poorly. For Etcd Raft, only with Claude-Sonnet-4, the modeling agent reaches the conformance and invariant checking, and scores are low. Clearly, the complexity and size of Etcd Raft exceed the modeling ability of the LLMs and agents.

For Etcd Raft, the basic modeling agents struggle with (1) code verbosity, (2) protocol complexity, and (3) abstraction. Etcd Raft has much more code than Spinlock, with low-level utilities (e.g., for debugging) and implementation-specific comments, which often cause agents to lose focus on essential system logic. Moreover, the Raft protocol (Ongaro & Ousterhout, 2014) has more complex logic than a spinlock in terms of ordering and intricate conditions of state transitions. Both (1) and (2) make Etcd Raft significantly more challenging for LLMs to comprehend the system artifact. For (3), Etcd Raft presents significant abstraction challenges: concepts like distributed logs require nested data structures, demanding LLMs to precisely express them using TLA⁺ language constructs.

The basic modeling agents also perform poorly on PGo systems (Appendix I.2), indicating limited LLM ability to comprehend machine-generated systems. Code in PGo-generated systems is a mix of compiler-generated patterns and a runtime library (Appendix E). The generated code is repetitive, and, while it borrows some variable names from the source specification, intermediate variables have synthetic, non-significant names, which provide few semantic clues to an LLM (or a human reader).

Analysis on Agents. For complex systems like Etcd Raft, the code translation agent outperforms the basic modeling agent. We believe this is due to the powerful translation abilities of LLMs (Yang et al., 2024b). Specifically, the code translation agent leverages symbolic control-flow analysis to synthesize a TLA⁺ model rigorously. The translation approach also prevents LLMs from hallucinating logic by adhering to system code. These results indicate that leveraging LLMs' code translation abilities can assist in model generation. Finally, we observed that LLMs would sometimes imitate classic TLA⁺ models from their training set, missing important system-specific content.

Analysis on Invariants. For invariants, LLMs violate very different types of invariants—only 8.3% of safety properties are violated while 41.9% of liveness properties were violated (Figure 4c). This indicates the limited ability of LLMs in temporal reasoning. To understand the nature of these violations, we conducted a fine-grained analysis categorizing them by root causes (Appendix I.1). We find that while fairness assumption violations (e.g., missing or incorrectly specified fairness assumptions) are a significant issue across systems, logical and structural errors tend to manifest earlier and block progress before fairness-related issues emerge.

Analysis on LLMs. We observe that LLMs constantly introduce syntax errors (Figure 4a), especially GPT-5, Gemini-2.5-Pro, and DeepSeek-R1. For example, DeepSeek-R1 often misuses mathematical symbols (e.g., \cap , \forall) instead of ASCII TLA⁺ operators. Gemini-2.5-Pro and GPT-5 often mix TLA⁺ syntax with those of other programming languages like Python. LLMs also misuse operators with incorrect parameters and produce malformed indentation. In terms of runtime errors (Figure 4b), LLMs frequently generate inconsistent TLC configurations, such as missing constants or mismatched declarations. Misunderstanding of TLA⁺ data structures is also a common error, e.g., comparing incompatible types or applying invalid operations (e.g., set operations on records).

Among all evaluated LLMs, Claude-Sonnet-4 in general outperforms others in most metrics across evaluated system artifacts. Since only syntax-valid models can proceed to subsequent evaluation phases, Claude-Sonnet-4's ability to generate syntactically correct TLA⁺ models provides an initial advantage. However, Claude-Sonnet-4's strength extends beyond syntax correctness. SYS-

486 MOBENCH decomposes the evaluation into four distinct metrics that separate syntactic correctness
 487 from reasoning about system behavior. As shown in the Appendix I.2, for models that successfully
 488 pass syntax checks, Claude-Sonnet-4 generally still achieves higher scores on runtime, conformance,
 489 and invariant metrics compared to other LLMs.

490 **Qualitative Assessment.** We conducted qualitative evaluation to assess AI-generated system model
 491 quality and utility in terms of bug finding (Appendix C). Comparing with human-written TLA⁺
 492 models, AI-generated TLA⁺ models differ in structure and completeness but they capture essential
 493 system behaviors. Despite these limitations, AI-generated models have successfully reproduced
 494 known bugs in five systems, demonstrating their practical utility for partial correctness checking.
 495

496 6 RELATED WORK

497 SYSMOBENCH is the first framework that evaluates AI on formally modeling real-world systems.
 498

499 **Benchmarks for Formal Specifications.** There are several benchmarks for evaluating AI (including
 500 LLMs and AI agents) on generating function-level pre-/post-conditions and loop invariants (Rego
 501 et al., 2025; Xie et al., 2025; Cao et al., 2025; Chakraborty et al., 2025; Ma et al., 2025; Wen et al.,
 502 2024). Those benchmarks typically use small programs, such as sample programs in VeriFast that
 503 implement data structures (Rego et al., 2025) and LeetCode programs (Ma et al., 2025). There also
 504 exist benchmarks on proof generation for deductive software verification (Yang et al., 2024a) and
 505 on verified code generation (Thakur et al., 2025; Ye et al., 2025). None of these benchmarks target
 506 complex real-world computing systems as in SYSMOBENCH. Fundamentally, those benchmarks
 507 evaluate AI’s abilities of code comprehension and specification, not system modeling. Similarly,
 508 **PAT-Agent** (Zuo et al., 2025) and **Alloy-APR** (Alhanahnah et al., 2025) target smaller tasks such as
 509 puzzles and repairing injected errors (see Appendix B.3). As AI for code is becoming mature, the
 510 next step is capturing how AI can benefit practical verification of real-world systems. We developed
 511 SYSMOBENCH with this motivation in mind. The arguably most related benchmark is TLAiBench
 512 (2025) which evaluates AI-generated TLA⁺ specifications. Tasks in TLAiBench are primarily logic
 513 puzzles, not real-world systems. TLAiBench is useful for evaluating AI’s ability in *using* the TLA⁺
 514 language, not system comprehension or modeling. Hence, TLAiBench and related benchmarks such
 515 as Cao et al. (2025) only measure the syntax and runtime correctness of the TLA⁺ specifications. Li
 516 et al. (2025) develop a benchmark for inference of system calls of Hyperkernel; however, the bench-
 517 mark does not consider distributed systems, concurrency, and assumes a ground-truth specification.
 518

519 Our evaluation aims to establish a baseline using simple, straightforward agents to reflect the status
 520 quo of today’s generative AI technologies. More advanced agents, especially those equipped with
 521 domain-specific knowledge and specialized techniques such as Bhatia et al. (2024); Wang et al.
 522 (2025), can be developed to improve the quality of AI-generated models.
 523

524 **General AI Benchmarks.** SYSMOBENCH differs from general AI reasoning benchmarks such as
 525 MMLU (Hendrycks et al., 2021), ARC (Clark et al., 2018), and HELM (Liang et al., 2022). These
 526 benchmarks evaluate generic reasoning, knowledge, and problem-solving capabilities across diverse
 527 domains, while SYSMOBENCH focuses on the specific task of formally modeling large, complex
 528 software systems as a foundation of formal system verification. SYSMOBENCH also differs from
 529 benchmarks targeting AI agent safety such as Agent-SafetyBench (Zhang et al., 2024). It currently
 530 targets traditional distributed and concurrent systems that are implemented in system code without
 531 neural components. The formal system modeling tasks evaluated by SYSMOBENCH are not covered
 532 by existing benchmarks such as EvalScope (EvalScope, 2024).

533 7 CONCLUDING REMARKS

534 This paper presents SYSMOBENCH, a new benchmark for evaluating generative AI in formally
 535 modeling real-world computing systems. SYSMOBENCH pushed us to articulate the criteria of for-
 536 mal system models and to develop metrics that can be collected automatically. We find that modern
 537 AI, despite showing strong abilities in coding and bug fixing, is still limited in comprehending, ab-
 538 stracting, and specifying large, complex systems. We hope to use SYSMOBENCH as a vehicle to
 539 advance AI technologies towards software system intelligence, rather than code intelligence.

540 We are actively adding new system artifacts to SYSMOBENCH and improving the benchmark’s
 541 usability. We encourage others to contribute their system artifacts to SYSMOBENCH. We are also
 542 exploring ways to measure the maintainability of AI-generated system models and considering ways
 543 to include human evaluation as part of SYSMOBENCH.

540 ETHICS STATEMENT
541

542 We strictly obeyed the principles outlined in the ICLR Code of Ethics, and carefully examined
543 potential ethical concerns, including potential impacts on human subjects, practices to data set re-
544 leases, potentially harmful insights, methodologies and applications, potential conflicts of interest
545 and sponsorship, discrimination/bias/fairness concerns, privacy and security issues, legal compli-
546 ance, and research integrity issues. We do not identify any potential risks. In fact, we believe
547 that the work, together with its artifacts (e.g., the TLA⁺ models) will have positive impacts on the
548 correctness of real-world computing systems and infrastructures.

549
550 REPRODUCIBILITY STATEMENT
551

552 We have made faithful efforts to ensure the reproducibility of our work. We have provided the
553 details of our work in the paper and its appendix, including the prompts, implementations, and
554 complete results. We have open-sourced all the research artifacts described in this paper, and created
555 an anonymous snapshot at <https://anonymous.4open.science/r/SysMoBench-BA9F/> for the
556 paper review, which documents how to use and extend different parts of the benchmark. We expect
557 that readers can easily reproduce our results reported in the paper. We also maintain an active forum
558 to assist with reproduction problems and questions on how to use and build on SYSMOBENCH.

756 **A ALTERNATIVE METRICS**
757758 No metric is perfect. Besides the core metrics presented in the paper, **SYSMOBENCH** also measures
759 complementary metrics that provide different measures of the system model quality.
760761 **A.1 RUNTIME PASS RATE**
762763 **SYSMOBENCH** repeatedly runs an agent to generate multiple TLA^+ system models and evaluates
764 whether each system model passes the runtime checks. The runtime pass rate is defined as $M_{ar} = \frac{n_{ar}}{n_{at}}$,
765 where n_{ar} is the number of TLA^+ models that passed runtime checking, and n_{at} is the total
766 number of generated TLA^+ models. This metric complements the system model’s action-level
767 coverage metric M_r (see §3.2.2), as it reflects the agent’s ability and reliability to produce fully
768 executable TLA^+ models. Note that a high M_{ar} does not necessarily mean most actions in the
769 TLA^+ models are correct. Even if some actions may contain runtime errors but are never executed
770 during execution, the TLA^+ model can still pass runtime checking. Conversely, a low M_{ar} may
771 result from a small number of frequently failing actions rather than errors affecting many actions.
772773 **A.2 CONFORMANCE PASS RATE**
774775 **SYSMOBENCH** repeatedly executes the system code to generate multiple code traces and checks
776 which traces fully pass conformance checking. The conformance pass rate is defined as $M_{ac} = \frac{n_{ac}}{n_{at}}$,
777 where n_{ac} is the number of traces that passed conformance checking, and n_{at} is the total number of
778 traces generated. This metric complements the code action-level coverage metric M_c (see §3.2.3)
779 and provides a coarse-grained empirical measure of the TLA^+ model’s overall alignment with ob-
780 served system behavior. As with runtime correctness, a low M_{ac} does not necessarily indicate that
781 most actions are unconformed, while a high M_{ac} generally suggests better overall system model
782 quality, given sufficiently diverse traces.
783784 **B EXTENSIBILITY TO OTHER SPECIFICATION LANGUAGES**
785786 **SYSMOBENCH** is general to specification languages beyond TLA^+ . To demonstrate its extensibil-
787 ity, we extended **SYSMOBENCH** to support Alloy (Jackson, 2012) and PAT (Sun et al., 2009).
788789 **B.1 SUPPORTING PAT AND ALLOY**
790791 **PAT**, PAT (Process Analysis Toolkit) is a formal verification framework for concurrent and real-time
792 systems. Supporting PAT in **SYSMOBENCH** is straightforward because PAT’s tooling provides a
793 workflow similar to TLA^+ . We leverage PAT’s parser for syntax checking, its simulator for runtime
794 evaluation, and its assertion mechanism with model checking for invariant validation. Conformance
795 is evaluated using PAT’s native trace refinement checker. We implement adaptors to translate our
796 concrete system traces into the PAT format, which are then validated against the PAT models.
797798 **Alloy**. Alloy is a declarative specification language based on first-order relational logic. For Alloy
799 support, evaluating syntax, runtime, and invariant correctness is straightforward using the Alloy An-
800 alyzer tool. Since Alloy does not provide a built-in notion of “action” as in TLA^+ , we adapt the
801 runtime metric by computing the proportion of variables and fields that become instantiated during
802 bounded execution. This metric is analogous to the action-trigger coverage in TLA^+ , and it indicates
803 whether a model executes normally and whether certain branches are unreachable. For the confor-
804 mance metric, we express a concrete system trace into Alloy facts, which are global constraints over
805 a bounded sequence of states and must hold in all generated instances, for trace validation.
806807 **B.2 EVALUATION RESULTS**
808809 We evaluated the basic modeling agent with four LLMs (Claude-Sonnet-4, GPT-5, Gemini-2.5-Pro,
810 and DeepSeek-R1) on generating Alloy and PAT models for the Spinlock system, with three attempts
811 per LLM. Table 4 shows the results. For both PAT and Alloy, the four evaluation metrics (syntax,
812 runtime, conformance, and invariant) remain applicable. However, due to limitations of current
813 tools, syntax checking for PAT and Alloy does not yet support partial scoring as in TLA^+ .
814

810
811 Table 4: Preliminary results of Alloy and PAT support on Asterinas Spinlock using the basic model-
812 ing agent (3 attempts per LLM).

Language	LLM	Syntax	Runtime	Conformance	Invariant
Alloy	Claude-Sonnet-4	0.00%	0.00%	0.00%	0.00%
	GPT-5	100.00%	0.00%	0.00%	0.00%
	Gemini-2.5-Pro	0.00%	0.00%	0.00%	0.00%
	DeepSeek-R1	0.00%	0.00%	0.00%	0.00%
PAT	Claude-Sonnet-4	0.00%	0.00%	0.00%	0.00%
	GPT-5	0.00%	0.00%	0.00%	0.00%
	Gemini-2.5-Pro	0.00%	0.00%	0.00%	0.00%
	DeepSeek-R1	0.00%	0.00%	0.00%	0.00%

823
824 The AI-generated Alloy and PAT models are poor compared to TLA⁺ models. For Alloy, only GPT-
825 5 was able to generate a model that passes the syntax correctness check after multiple attempts, but
826 the generated model scored 0% on runtime correctness. For PAT, none of the evaluated LLMs
827 demonstrated familiarity with the PAT syntax—all generated PAT models failed syntax checks.828 Our analysis reveals that current LLMs are unfamiliar with the syntax of Alloy and PAT. In practice,
829 nearly all generated models failed at the parsing or type-checking stage. For PAT, LLMs frequently
830 produced syntax borrowed from other languages such as C, Promela, or PRISM. For example, chan-
831 nels were often declared using PRISM-style range expressions (e.g., `channel1 acquire:{0..2};`)
832 which PAT does not support. We also observed the introduction of keywords and type annotations
833 that do not exist in PAT, such as adding explicit types (`int`) after variables or using `chan` instead of
834 PAT’s actual channel declaration syntax. For Alloy, we observed similarly systematic breakdowns.
835 A common pattern was referencing signatures (types) that were never declared in the model, such
836 as using `Time` in module imports without defining what `Time` is. The models also wrote constraints
837 that mixed incompatible language features, which Alloy does not accept.838 We believe that the weak model capabilities using PAT and Alloy are primarily because Alloy and
839 PAT are much less popular than TLA⁺ in real-world systems. Consequently, LLMs are not exten-
840 sively trained on these languages, resulting in poor generation quality. These results justify the use
841 of TLA⁺ as the specification language of choice for SYSMOBENCH.

842 B.3 COMPARISON WITH RELATED WORK

843
844 PAT-Agent (Zuo et al., 2025) and Alloy-APR (Alhanahnah et al., 2025) also evaluate AI’s ability
845 to work with formal models using PAT and Alloy, reporting promising results on their benchmarks.
846 However, their tasks and complexity differ fundamentally from SYSMOBENCH. Table 5 summa-
847 rizes the task of each work.

848 Table 5: Summary of the tasks of each work.

Work	Task
SYSMOBENCH	Generating formal models for real-world software systems from their source code.
PAT-Agent	Generating formal models from natural language descriptions.
Alloy-APR	Repairing an existing model with injected errors.

855 Because these tasks are inherently different, it is difficult to compare their complexity directly. In-
856 stead, we compare the complexity of the generated formal models as shown in Table 6.857
858 Table 6: Complexity comparison across benchmarks measured by lines of code of formal models.

Benchmark	Smallest	Largest	Median	Task Type
SYSMOBENCH	75	508	219	Generation
PAT-Agent	16	142	45	Generation
Alloy-APR (ARepair)	15	99	50	Repair
Alloy-APR (Alloy4Fun)	1	234	21	Repair

864 Compared with the generation task in PAT-Agent, most models we expect LLMs/agents to generate
 865 in **SYSMOBENCH** are larger than the largest models in the PAT-Agent paper. PAT-Agent’s tasks
 866 are small samples such as river-crossing puzzles and restaurant workflows, not real-world software
 867 systems. Alloy-APR’s tasks are similar, which come from ARepair and Alloy4Fun; neither of them
 868 uses real-world system artifacts.

869 To further validate our understanding, we reproduced the results of Alloy-APR and PAT-Agent using
 870 the same LLMs evaluated in **SYSMOBENCH**. For Alloy-APR, we used the official artifact on the
 871 ARepair benchmark. Table 7 shows the results.
 872

873 Table 7: Reproduction of Alloy-APR results on ARepair benchmark with LLMs used in **SYS-**
 874 **MOBENCH**.

Model	Correct Items	Success Rate
Claude-Sonnet-4	38 / 38	100.0%
GPT-5	30 / 38	78.9%
Gemini-2.5-Pro	14 / 38	36.8%
DeepSeek-R1	5 / 38	13.2%
Best result in Alloy-APR	28 / 38	73.7%

882 Our reproduction results show that Claude-Sonnet-4 and GPT-5 outperform the best results reported
 883 in the Alloy-APR paper. This suggests that existing LLMs can solve these repair tasks effectively—
 884 the high scores in the paper are largely due to the fact that the task itself is relatively simple. In
 885 contrast, our results show that these LLMs still struggle to generate syntax-correct Alloy models
 886 from complex system code in **SYSMOBENCH** (see Table 4).
 887

888 For PAT-Agent, we ran the NoPlanning workflow using the LLMs evaluated in **SYSMOBENCH**.
 889 This workflow is similar to our Basic Modeling Agent: it calls the LLM to generate a PAT model
 890 and then iteratively fixes errors. Table 8 shows the results.
 891

892 Table 8: Reproduction of PAT-Agent results using NoPlanning workflow with LLMs from **SYS-**
 893 **MOBENCH**. CSR: Compilation Success Rate, FPR: Full Pass Rate, APR: Average Pass Rate.

Model	CSR	FPR	APR
Claude-Sonnet-4	84.6%	80.8%	87.3%
GPT-5	84.6%	69.2%	76.4%
Gemini-2.5-Pro	84.6%	65.4%	74.8%
DeepSeek-R1	57.7%	50.0%	54.9%

894 The results are consistent with the original paper’s findings. Similar to Alloy-APR, current LLMs
 895 can solve these relatively simple tasks to a reasonable extent (e.g., Claude-Sonnet-4 achieves 87.3%
 896 APR). However, their ability to generate formal models for real-world software systems is much
 897 weaker, as evidenced by our results (see Table 4).
 898

900 These results suggest that existing benchmarks such as PAT-Agent and Alloy-APR mostly exercise
 901 simplified modeling tasks. In contrast, **SYSMOBENCH** targets formal models derived from real sys-
 902 tem code, where current LLMs often fail to produce even syntax-correct specifications (see Table 4).
 903

904 C QUALITATIVE EVALUATION OF AI-GENERATED MODELS

905 Beyond the automated quantitative metrics, we performed qualitative evaluation to assess the prac-
 906 tical utility of AI-generated models for human engineers. We evaluated AI-generated models in two
 907 aspects: (1) comparison with human-written ground-truth models from the community, and (2) their
 908 ability to reproduce known bugs in system code.
 909

910 C.1 COMPARISON WITH HUMAN-WRITTEN MODELS

911 To assess the quality of AI-generated models, two human experts evaluated models produced by two
 912 different agents: the basic modeling agent and the code translation agent. Each expert compared AI-
 913 generated TLA⁺ models against human-written models for nine of the systems in **SYSMOBENCH**.
 914

918 The experts identified ten main types of differences between AI-generated and human models (Tables 9 and 10 summarize their occurrence across systems and LLMs):
 919
 920

921 1. Unnecessary EXTENDS/INSTANCE statements
 922 2. Topics present in the human model but missing in AI models
 923 3. Topics introduced by AI but absent in the human model
 924 4. Fewer comments compared to human models
 925 5. Properties present in human models but not in AI models
 926 6. Different fairness assumptions compared to human models
 927 7. Longer composite actions in AI models
 928 8. Overly complex or random fairness conditions
 929 9. Overspecialization with hard-coded values instead of parameters
 930

931 Table 9: Types of differences between AI-generated models (produced by the basic modeling agent)
 932 and human-written models. Numbers refer to the types listed above.

System	Claude-Sonnet-4	GPT-5	Gemini-2.5-Pro	DeepSeek-R1
Asterinas Spin	1, 3	1, 5, 8	1, 5, 8	1, 5, 8
Asterinas Mutex	1, 5	1, 5	1, 5, 9	5
Asterinas Rwmutex	1, 5	1, 5	1, 5	1, 5
Etc Raft	1, 2, 4, 5, 7	1, 2, 4, 5	1, 2, 4, 5, 7	1, 2, 4, 5, 7

PGo dqueue	1, 5	1, 5	1, 5	1, 5, 7
PGo locksrv	1, 5	1, 5	1, 5	5, 6, 7, 8
PGo raftkvs	1, 5, 7	1, 5, 7, 8	1, 5, 8	1, 5

933 Table 10: Types of differences between AI-generated models (produced by the code translation
 934 agent) and human-written models. Numbers refer to the types listed above.

System	Claude-Sonnet-4	GPT-5	Gemini-2.5-Pro	DeepSeek-R1
Asterinas Spin	1, 2, 3, 5, 6	1, 3, 5, 6, 8	1, 2, 3, 5, 6	1, 2, 3, 5, 6, 8
Asterinas Mutex	1, 2, 5, 8	1, 2, 5	1, 2, 5	1, 2, 5, 8
Asterinas Rwmutex	1, 5, 6	1, 3, 5, 6, 8	1, 3, 5, 6	1, 5, 6, 8
Etc Raft	1, 2, 4, 5, 6, 8	1, 2, 4, 5, 6	1, 2, 4, 5, 6, 7	1, 2, 4, 5, 6, 7
Redis Raft	1, 3, 4, 5	1, 3, 4, 5	1, 3, 4, 5	1, 2, 4, 5, 6
Xline CURP	1, 4, 5, 6	4, 5, 6	1, 2, 4, 5, 6	1, 4, 5, 6
PGo dqueue	1, 2, 3, 5, 6	1, 5, 6	1, 5, 6	1, 3, 5, 6
PGo locksrv	1, 5	1, 5, 8	1, 5	1, 5, 6, 8
PGo raftkvs	1, 5, 7	1, 5, 7, 8	1, 5, 6, 7, 8	1, 5, 6, 7

956 We group and discuss these differences below.

957 **Prompt-induced patterns (types 1, 4, 5).** For both agents, many AI models include unnecessary
 958 EXTENDS / INSTANCE statements (type 1), lack comments (type 4), and omit certain properties (type
 959 5). These patterns largely result from our prompting and evaluation design. The prompt requires
 960 including common libraries to avoid syntax errors; this does not harm correctness or the evaluation
 961 of AI’s modeling capability, as human experts also sometimes copy-paste EXTENDS with unneces-
 962 sary dependencies. Missing comments and properties are expected, as SYSMOBENCH focuses on
 963 state/action modeling and does not require comment or property generation.

964 **Model utility (types 2, 3, 6, 8, 9).** AI-generated models may miss certain variables or actions (type
 965 2) or include extra details (type 3), especially when there is a significant difference in abstraction
 966 levels between the human-written models and AI-generated models. For instance, the code transla-
 967 tion agent tends to produce more concrete specifications compared to human-written ones, leading
 968 to more frequent occurrences of type 2 (missing topics) and type 3 (extra topics). Fairness defini-
 969 tions (types 6 and 8) of AI-generated models often differ from human models or are overly technical
 970 or random, which can affect liveness checking. There are also isolated cases of overspecialization
 971 (type 9). Overall, these differences show that AI models capture the general structure but may vary
 in completeness, fairness, and abstraction compared to human models.

972 **Readability and documentation (types 4, 7).** For both agents, the issue of fewer comments (type
 973 4) is due to our prompt design; when we removed the instruction not to generate comments, AI
 974 models produced reasonably long comments that are easy to read. Some models also contain long
 975 composite actions (type 7) or use unconventional ordering of structure (e.g., `TypeOK` checks placed
 976 unusually). Nevertheless, AI-generated models from both agents remain generally readable, with
 977 meaningful variable and action names and understandable structure.

979 C.2 BUG REPRODUCTION

981 AI-generated models can be practically useful for partial correctness checking. Without any hints
 982 about specific bugs, AI-generated models successfully reproduced several hard-to-find bugs across
 983 multiple systems in `SYSMOBENCH`. Table 11 lists these reproduced bugs with links to the corre-
 984 sponding issue reports or pull requests.

985 986 Table 11: Bugs successfully reproduced by AI-generated models.

987 Bug ID	988 Description
988 Etcd Raft #10998	Learners cannot vote during promotion causing election failure
989 Xline CURP #402	Cluster will enter a frozen state after multiple crashes and recoveries
990 Redis Raft #19	Stale reads under process pauses, violating linearizability
991 Asterinas Mutex #1279	Failed <code>try_lock</code> incorrectly unlocks mutex breaking mutual exclusion
992 Asterinas Rwmutex #1303	Lost wakeup when upgradeable reader releases lock

993 These bugs were discovered by having AI agents generate TLA^+ models from earlier versions of
 994 the system code and then using model checking to identify the issues.

996 D EXAMPLES OF AI-GENERATED TLA^+ MODELS

999 We present two AI-generated system models. Figures 5 and 6 show the TLA^+ model and its cor-
 1000 responding TLC configuration for Asterinas Spinlock generated by the basic modeling agent with
 1001 Claude-Sonnet-4. Figures 7 and 8 show the TLA^+ model and its corresponding TLC configuration
 1002 for Etcd Raft generated by the code translation agent with Claude-Sonnet-4.

E PGO-COMPILED SYSTEMS

Table 1 lists all the system artifacts in **SYSMOBENCH**. Unlike other open-source systems implemented mostly by human developers, PGo systems represent a special kind of compiler-generated systems. PGo is a compiler converting distributed systems specifications written in a DSL of TLA⁺ into executable systems implementations in Go (Hackett et al., 2023a).

These systems reflect production use cases:

- 1296 • `dqueue` is a simple distributed queue with producers and consumers, which represents a common
1297 cloud computing mechanism. Similar distributed queues are available from many cloud platforms,
1298 like Amazon SQS, Cloudflare Queues, or Apache Kafka.
- 1299 • `locksvc` is a simple distributed locking system, which represents a common distributed systems
1300 concept.
- 1301 • `raftkvs` is a verified distributed key-value store, with competitive performance. For its consensus
1302 implementation, `raftkvs` specifies Raft (Ongaro & Ousterhout, 2014).

1303 These systems are complex, each requiring several person-days of effort to specify. The `raftkvs` store
1304 is particularly complex, requiring almost a person-month of effort. While they are developed using
1305 a formal modeling language, these systems also account for practical coding concerns. Each system
1306 compiles to usable, non-trivial Go code. Notably, `raftkvs` outperforms other formally verified key-
1307 value stores, with 41% higher throughput than the next-best formally verified store implementation,
1308 and similar latency but 21% of the throughput achieved by `Etdc`.

1309 A challenge unique to system modeling is that PGo-compiled systems contain machine-generated
1310 Go code, which includes unusual abstractions and coding patterns. For instance, the generated code
1311 makes extensive use of abstractions from PGo’s runtime support library, while containing many
1312 synthetically named variables. These issues are representative of realistic engineering scenarios,
1313 such as generated code (macros, parser generators, state machines), or situations where the original
1314 source code is lost (decompilation artifacts). This type of source code input currently leads to poor
1315 performance on our benchmarks.

1316 **PGo Trace Validation.** For AI-generated system models, we must validate their behavior against
1317 gathered execution traces. PGo’s TraceLink feature provides a different trace validation method than
1318 for hand-written systems, allowing for automatic implementation tracing and TLA⁺ glue generation.
1319 As a result, no additional work is needed to gather traces. For simplicity, we use traces taken from
1320 TraceLink’s published artifact. From these traces, TraceLink is able to generate its own binding
1321 TLA⁺, mapping these logs precisely to a TLA⁺ state space.

1323 F SYSMOBENCH EVALUATION PROMPTS

1325 During `SYSMOBENCH` evaluation, LLMs are invoked for conformance and invariant correctness
1326 evaluation to extract information, map actions and variables, and concretize invariants based on
1327 invariant templates.

1329 We show the complete prompts used for benchmark evaluation. These prompts are templates with
1330 parameterized fields that are instantiated by task-specific information. For demonstration, we in-
1331 stantiate the fields in the task for modeling `Etdc Raft`, with the instantiated parts marked in green.

1332 F.1 CONFORMANCE EVALUATION PROMPTS

1334 Two prompts extract model information and map model action and variable names to code, both
1335 generating configuration files for script processing to support trace validation.

1337 **Model component extraction.** This prompt directs an LLM to extract TLA⁺ model components,
1338 such as constants, variables, and actions, which are used by a script to generate a *trace specification*
1339 (Cirstea et al., 2024). A trace specification constrains state space exploration along the code
1340 trace path to verify whether a model state space path matches the code trace. In the prompt, the
1341 `{source_code}` field is instantiated with the TLA⁺ model.

1342 Model Component Extraction Prompt

1343 Generate a YAML configuration file from the provided TLA+ model (.tla) and configuration (.cfg) files.
1344 Extract information according to the following rules:

```
1345 ## Task Description
1346 Parse the TLA+ model and configuration files to create a structured YAML configuration that captures the
1347 model name, constants, variables, actions, and interactions.

1348 ## Extraction Rules
```

```

1350
1351     ### spec.name
1352     Extract from the module declaration line: `---- MODULE <ModuleName> ----`
1353     The spec.name is the ModuleName between "---- MODULE" and "----".
1354
1355     ### constants
1356     Extract from the CONSTANTS section in the .cfg file.
1357     - name: The constant identifier
1358     - value: The assigned value, formatted as:
1359     - Sets: Wrap in single quotes, e.g., '{s1, s2, s3}' becomes '{"s1", "s2", "s3"}'
1360     - Strings: Wrap in single quotes with double quotes inside, e.g., Nil becomes '"Nil"'
1361     - Numbers: Wrap in single quotes as string, e.g., 5 becomes '5'
1362
1363     ### variables
1364     Extract from the Init operator definition in the .tla file.
1365     For each variable assignment in Init:
1366     - name: The variable name
1367     - default.value: The initial value expression (preserve TLA+ syntax, escape backslashes)
1368
1369     ### actions
1370     Extract from the Next operator definition. Include only direct action calls (not numbered interactions).
1371     For each action:
1372     - name: The action/operator name
1373     - parameters: List of parameters with:
1374     - name: Parameter variable name
1375     - source: Where the parameter comes from (e.g., Server, messages)
1376     - stmt: The complete statement as it appears in Next (including any conditions)
1377
1378     ### interactions
1379     Extract from the Next operator definition. Include only numbered intermediate actions.
1380     Just list the names (e.g., HandletickElection_1, HandletickHeartbeat_1)
1381
1382     ## Example
1383     Given this TLA+ model:
1384
1385     ---- MODULE SimpleSpec ----
1386     ...
1387     Init ==
1388     /> x = 0
1389     /> y = [s \in Server |-> 0]
1390
1391     Next ==
1392     /> \E s \in Server : Action1(s)
1393     /> \E m \in messages : Action2(m)
1394     /> IntermediateAction_1
1395
1396     And this configuration:
1397
1398     CONSTANTS
1399     Server = {s1, s2}
1400     MaxValue = 10
1401
1402     Generate this YAML:
1403
1404     ```yaml
1405     spec.name: SimpleSpec
1406     constants:
1407     - name: Server
1408     value: '{"s1", "s2"}'
1409     - name: MaxValue
1410     value: '10'
1411     variables:
1412     - name: x
1413     default.value: '0'
1414     - name: y
1415     default.value: '[s \in Server |-> 0]'
1416     actions:
1417     - name: Action1
1418     parameters:
1419     - name: s
1420     source: Server
1421     stmt: Action1(s)
1422     - name: Action2
1423     parameters:
1424     - name: m
1425     source: messages
1426     stmt: Action2(m)

1404 interactions:
1405 - name: IntermediateAction.1
1406 ``
1407
1408 ## Important Notes
1409 1. Return ONLY the YAML content - no explanations, comments, or natural language
1410 2. Preserve TLA+ syntax exactly in default_value fields (escape backslashes)
1411 3. For actions with conditions, include the full stmt as it appears in Next
1412 4. Ignore variables that appear in Init but are not part of the main model (e.g., pc, info, stack)
1413 5. Order matters: spec.name, constants, variables, actions, interactions
1414
1415 Generate the YAML configuration based on the provided TLA+ files:
1416 {source_code}

```

1416 **Model and code component mapping.** This prompt directs an LLM to map code to model variable naming for trace validation comparison. The LLM generates a JSON file storing the mappings, which is further processed by a script to output a test harness that aligns code trace variable and action names with the model. In the prompt, the `{TLA_SPEC_CODE_PLACEHOLDER}` field is instantiated with the TLA⁺ model, and `{IMPLEMENTATION_CODE_PLACEHOLDER}` with the corresponding code.

1421 **Model and Code Component Mapping Prompt**

1422 You are tasked with generating a JSON mapping file that defines how to convert a concurrent or
1423 distributed system traces to TLA+ model format for trace validation.

1424 `## System Overview`

1425 `etcd Raft is a distributed consensus algorithm implementation that supports:`
1426 - Leader election with terms and prevoting/voting
1427 - Log replication across multiple nodes
1428 - State transitions between Follower, Candidate, and Leader roles
1429 - Message passing between nodes

1430 `## Code Analysis`
1431 Before generating the mapping, you need to analyze the relevant code to understand the system behavior:

1432 `**CRITICAL**:` You MUST base your mapping on the actual TLA+ model content, NOT on the examples below.
1433 The examples are for format reference only. Always use the actual variables and actions defined in the
1434 provided model.

1435 `### TLA+ Model Code`
1436 ````tla+`
1437 `{TLA_SPEC_CODE_PLACEHOLDER}`
1438 `````

1439 `### Implementation Code`
1440 ````go`
1441 `{IMPLEMENTATION_CODE_PLACEHOLDER}`
1442 `````

1443 `## Input: System Trace Format`

1444 System traces are in JSONL format with events like:
1445 ````json`
1446 `{ "conf": [[{"1", "2", "3"}, []], "log": 0, "name": "InitState", "nid": "1", "role": "StateFollower", "state": {"commit": 0, "term": 0, "vote": "0"}}`
1447 `{ "conf": [[{"1", "2", "3"}, []], "log": 1, "name": "BecomeCandidate", "nid": "1", "role": "StateCandidate", "state": {"commit": 0, "term": 1, "vote": "0"}}`
1448 `{ "conf": [[{"1", "2", "3"}, []], "log": 1, "name": "BecomeCandidate", "nid": "2", "role": "StateCandidate", "state": {"commit": 0, "term": 1, "vote": "0"}}`
1449 `````

1450 Common actions in system traces:
1451 - BecomeFollower: Transition to follower role
1452 - BecomeCandidate: Transition to candidate role
1453 - BecomeLeader: Transition to leader role
1454 - Ready: Node is ready for operations
1455 - PreVote/Vote: Cast prevote/vote during election
1456 - AppendEntries: Replicate log entries
1457 - Heartbeat: Send/receive heartbeat messages

1458 `## Target: TLA+ Model Variables`

```

1458
1459 The TLA+ model tracks these state variables:
1460 - currentTerm: Current term number for each node
1461 - state: Node role (Follower, Candidate, Leader)
1462 - votedFor: Which candidate this node voted for in current term
1463 - commitIndex: Index of highest log entry known to be committed
1464 - nextIndex: For leaders, next log entry to send to each server
1465 - matchIndex: For leaders, highest log entry known to be replicated on server
1466
1467 ## Required Mapping Structure
1468
1469 Generate a JSON file with this structure:
1470
1471 ````json
1472 {
1473   "config": {
1474     "Server": ["Server1", "Server2", "Server3"] // List of node identifiers
1475   },
1476   "events": {
1477     // Map system actions to TLA+ events
1478     "InitState": "Init",
1479     "BecomeFollower": "BecomeFollower",
1480     "BecomeCandidate": "BecomeCandidate",
1481     "BecomeLeader": "BecomeLeader",
1482     "Ready": "Ready",
1483     "Vote": "Vote",
1484     "AppendEntries": "AppendEntries",
1485     "Heartbeat": "Heartbeat",
1486     // Add other mappings as needed based on code analysis
1487   },
1488   "node_mapping": {
1489     // Map string node IDs to node names
1490     "1": "Node1",
1491     "2": "Node2",
1492     "3": "Node3",
1493     // Continue as needed
1494   },
1495   "role_mapping": {
1496     // Map system roles to TLA+ states
1497     "StateFollower": "Follower",
1498     "StateCandidate": "Candidate",
1499     "StateLeader": "Leader"
1500   }
1501 }
1502 ````

1503
1504 ## Implementation Notes
1505 1. The mapping will be used by a state tracker that maintains complete system state
1506 2. Server IDs in traces are numeric (0, 1, 2...) and must be mapped to "Server1", "Server2", etc.
1507 3. The state tracker will automatically handle state transitions based on actions
1508 4. Focus on correctly mapping actions and Server states
1509 5. The config section should list all possible Server that might appear in traces
1510
1511 ## Your Task
1512 Generate a complete mapping.json file that:
1513 1. Maps all common actions to their TLA+ equivalents
1514 2. Provides server ID mappings for all servers that appear in traces
1515 3. Ensures compatibility with the state tracking implementation

```

F.2 INVARIANT CORRECTNESS EVALUATION PROMPT

This prompt concretizes invariants from given invariant templates to model-specific forms. It typically requires the LLM to map different names in an invariant template to the corresponding model elements. The `$tla_model` field is instantiated with the TLA⁺ model, and the `$invariant_templates` field with the invariant templates defined in the system artifact (see §3.2.4 for an example).

Invariant Concretization Prompt

You are a TLA+ expert specializing in distributed systems and Raft consensus. Your task is to implement a set of expert-written invariants for the given etcd TLA+ model.

Target Model

```

1512 $tla_model
1513
1514 ## Invariants to Implement
1515
1516 $invariant_templates
1517
1518 ## Implementation Requirements
1519
1520 1. **Deep Analysis**: First, thoroughly understand both the invariant template's semantic intent
1521 and the model's modeling approach:
1522 - What distributed consensus property does each template aim to verify?
1523 - How does the model represent server states, logs, terms, and leadership?
1524 - What are the semantic equivalents between template concepts and model implementation?
1525
1526 2. **Semantic Mapping**: For each invariant, identify the conceptual mapping between template and
1527 model:
1528 - Template server state concepts -> Model's server state representation
1529 - Template log structure -> Model's log data structures and indexing
1530 - Template leadership concepts -> Model's leader election and term management
1531 - Template node/server sets -> Model's server constants and domains
1532
1533 3. **Creative Adaptation**: Translate the invariant while preserving its core safety/liveness meaning:
1534 - **DO NOT** simply replace variable names - understand the underlying distributed systems logic
1535 - **DO** redesign the predicate logic to fit the model's data structure granularity
1536 - **DO** use equivalent semantic concepts even if data representations differ
1537 - **PRESERVE** the original safety/liveness guarantees without weakening the property
1538
1539 4. **TLA+ Property Type Constraints**:
1540
1541 **FOR SAFETY PROPERTIES** (type: "safety"):
1542 - **MUST** be STATE PREDICATES (describe single states only)
1543 - **NEVER** use primed variables (`currentTerm`, `log`)
1544 - **NEVER** use temporal operators (`[]`, `<>`, `^>`)
1545 - **NEVER** reference actions (like `RequestVote(s)`, `AppendEntries(s,t)` - only use state variables
1546 - **ONLY** use unprimed variables (`currentTerm[s]`, `log[s]`) and constants
1547 - **CORRECT**: `LeaderUniqueness == \A term \in Terms : Cardinality({s \in Servers : state[s] = "leader" /\
1548 currentTerm[s] = term}) <= 1`
1549 - **INCORRECT**: `state[s] = "candidate" => RequestVote(s)` (references action RequestVote)
1550
1551 **FOR LIVENESS PROPERTIES** (type: "liveness"):
1552 - **MUST** be TEMPORAL FORMULAS (describe execution traces)
1553 - **MUST** use temporal operators (`<>`, `^>`) to express "eventually" or "leads-to"
1554 - **CORRECT**: `EventualLeaderElection == <>(\E s \in Servers : state[s] = "leader")`
1555
1556 5. **Constraint Compliance**:
1557 - Use ONLY variables, constants, and operators that exist in the model
1558 - Generate complete, syntactically valid TLA+ invariant definitions
1559 - Maintain the exact invariant names from templates
1560
1561 6. **Output format**: Return a JSON object containing an array of complete TLA+ invariant definitions
1562
1563 7. **EXACT naming requirement**: You MUST use the exact invariant names specified in the templates
1564 above. Do not create your own names.
1565
1566 ## Example Output Format
1567
1568 ````json
1569 {
1570   "invariants": [
1571     "LeaderUniqueness == \A term \in 1..MaxTerm : Cardinality({n \in Servers : state[n].role = "leader" /\
1572 state[n].currentTerm = term}) <= 1",
1573     "LogConsistency == \A n1, n2 \in Servers : \A i \in DOMAIN log[n1] : (i \in DOMAIN log[n2] /\
1574 log[n1][i].term = log[n2][i].term) => (\A j \in 1..i : log[n1][j] = log[n2][j])"
1575   ]
1576 }
1577
1578
1579 **CRITICAL REQUIREMENTS**:
1580 - **SEMANTIC PRESERVATION**: Each translated invariant MUST verify the same property as the original
1581 template
1582 - **CREATIVE ADAPTATION**: Do NOT simply omit invariants - find creative ways to express the same
1583 property using available model elements
1584 - **COMPLETENESS**: Aim to translate ALL invariants by understanding their semantic intent, not just
1585 their syntactic form
1586 - Use ONLY variables, constants, and operators that exist in the provided model
1587 - Use EXACTLY the invariant names from the templates (preserve exact names for evaluation consistency)
1588
1589

```

```

1566 - Return ONLY valid JSON, no explanatory text before or after
1567 - Each array element must be a complete TLA+ invariant definition: "InvariantName == <expression>"
1568 - For complex invariants, you may use multiline format within the JSON string (use actual line breaks)
1569 - For simple invariants, single line format is preferred
1570 - **LAST RESORT**: Only omit an invariant if its core concept is fundamentally incompatible with the
1571 model's design
1572 - **CRITICAL JSON ESCAPING RULES**:
1573 - TLA+ operators like `'\A'`, `'\E'`, `'\in` contain ONE backslash in the final TLA+ code
1574 - In JSON strings, use EXACTLY ONE backslash escape: write `"\\"A"` to get `'\A` in TLA+
1575 - **DO NOT double-escape**: `"\\"\\A` is WRONG and will produce `'\A` in TLA+
1576 - **CORRECT**: `"\LeaderUniqueness == \\\A term \\\in 1..MaxTerm : state[term] = \"leader\""`
1577 - **WRONG**: `"\LeaderUniqueness == \\\A term \\\in 1..MaxTerm : state[term] = \"leader\""`
1578 - Start your response immediately with the opening brace {
```

G BASIC MODELING AGENT

The basic modeling agent operates in two steps for each system artifact: (1) generating the model, including both the TLA⁺ model and its TLC configuration, and (2) using a feedback loop that takes SYSMOBENCH evaluation results to iteratively improve the generated TLA⁺ model. We show the complete prompts of the basic modeling agent (§4) to provide its detailed implementation.

G.1 MODEL GENERATION PROMPTS

TLA⁺ model generation. This prompt directs an LLM to generate the TLA⁺ model file, instantiated with the granularity definitions of the system artifact (see §3.1). The {file.path} and {source_code} fields are instantiated with the code file path in the repository and source code content, respectively.

TLA⁺ Model Generation Prompt

```

1590 You are an expert in formal verification and TLA+ models with deep expertise in concurrent and
1591 distributed systems, particularly etcd and Raft consensus
1592 .
1593
1594 Convert the following source code to a comprehensive TLA+ model.
1595
1596 System: etcd distributed key-value store
1597
1598 Source Code from {file.path}:
1599 ````go
1600 {source_code}
1601 `````
1602
1603 System-specific modeling requirements:
1604
1605 MANDATORY CORE ACTIONS (must include all):
1606 1. [Message Types] MsgHup (election timeout), MsgVote/MsgVoteResp (voting), MsgApp/MsgAppResp (log
1607 replication)
1608 2. [Node States] Four states: StateFollower, StateCandidate, StateLeader, StatePreCandidate (prevote
1609 enabled)
1610 3. [Leader Election] Complete prevote + vote phases: PreCandidate → Candidate → Leader transitions
1611 4. [Log Operations] Log entry appending, consistency checks, commitment with majority quorum
1612 5. [Heartbeat/Timeout] Election timeouts triggering campaigns, heartbeat prevention of elections
1613 6. [Client Proposals] MsgProp message handling and log entry creation by leaders
1614
1615 EXPLICITLY EXCLUDED (do not model):
1616 - Configuration changes and joint consensus (ConfChange messages)
1617 - Log compaction and snapshots (MsgSnap)
1618 - ReadIndex optimizations (MsgReadIndex)
1619 - Async storage operations (LocalAppendThread, LocalApplyThread)
- Advanced flow control and progress tracking details
1620
1621 REQUIRED BEHAVIORAL SCOPE:
1622 - Prevote phase (StatePreCandidate) must be modeled as it's enabled by default in etcd
1623 - State transition constraints: Follower → PreCandidate → Candidate → Leader (strict transitions)
1624 - Message processing by state: only valid message types handled in each node state
1625 - Term advancement rules: nodes advance term when receiving messages with higher term
1626 - Voting restrictions: one vote per term, term must be current or newer
1627 - Heartbeat mechanism: leaders send heartbeats, followers reset election timeout on receipt
1628 - Log consistency checks: prevLogIndex/prevLogTerm validation in MsgApp processing
```

```

1620 - Majority-based leader election and log commitment
1621 - Basic network message delays and losses
1622
1623 Generate a TLA+ model that accurately models the system's behavior.
1624 CRITICAL OUTPUT REQUIREMENTS:
1625 1. The MODULE name must be exactly "etcdraft"
1626 " (---- MODULE etcdraft ----)
1627
1628 2. Return ONLY pure TLA+ model code - no markdown code blocks (no ```tla or ```)
1629 3. Do not include any explanations, comments, or formatting markers
1630 4. Start your response directly with: ---- MODULE etcdraft
1631 ----
1632 5. End your response with the closing ====
1633 6. **DO NOT define invariants** (like MutualExclusion, Invariant, etc.) - focus on modeling the system
1634 behavior
1635 7. **MUST include EXTENDS statement**: The model must extend at least these modules: TLC, Sequences,
1636 SequencesExt, Naturals, FiniteSets, Bags
1637
1638
1639
```

TLC configuration generation. This prompt directs an LLM to generate a TLC configuration file. The configuration file requires the LLM's understanding of the system to make the model executable, such as designating the initial predicate and next-state relations. The `$tla_spec` field is instantiated with the TLA⁺ model generated in the previous step.

TLC Configuration Generation Prompt

You are a TLA+ expert. Generate a complete TLC configuration file (.cfg) for the `etcd` model that can be directly saved and used for model checking.

```

1640 ## Input Model:
1641
1642 $tla_spec
1643
1644 ## Requirements:
1645
1646 1. **Analyze the model** to identify the main model name and all declared constants
1647 2. **Generate complete .cfg file content** with SPECIFICATION, CONSTANTS sections
1648 3. **Use small values for constants** to ensure efficient model checking (2-3 servers, small integers)
1649 4. **Output ONLY the raw .cfg file content** - no explanations, no markdown, no code blocks
1650
1651 ## Example Output Format:
1652
1653 SPECIFICATION SpecName
1654
1655 CONSTANTS
1656 ...
1657
1658 **CRITICAL: Your response must contain exactly ONE complete .cfg file. Do not repeat any sections.
1659 Start your response immediately with "SPECIFICATION" and include nothing else.**
```

G.2 MODEL REFINEMENT PROMPT

This prompt provides guidance for the LLM to refine the previously generated model using syntax and runtime evaluation results from SYSMOBENCH. The `{current_model}` field contains the previous iteration's model, `{current_tlc_cfg}` contains the previous TLC configuration, `{syntax_errors}` contains the syntax errors reported by SANY, and `{runtime_errors}` contains the runtime errors reported by TLC.

Model Refinement Prompt

You are an expert TLA+ model specialist with extensive experience in concurrent and distributed systems modeling.

I need you to fix errors in a TLA+ model for `etcdraft` system.

```

1666 ## Current TLA+ Model
1667 ````tla
1668 {current_model}
1669 ````
```

```

1670 ## Current TLC Configuration
1671
1672
1673
```

```

1674 ...
1675 {current_tlc_cfg}
1676 ...
1677 ## Errors Found
1678 **Detailed Syntax Errors:** {syntax_errors}
1679 ...
1680 **Detailed Runtime Errors:** {runtime_errors}
1681 ...
1682 ## Correction Instructions
1683 This is correction attempt {attempt_number} of {max_attempts}.
1684 ...
1685 Please provide a corrected TLA+ model that fixes these errors. Your corrected model should:
1686
1687 1. **Fix all syntax errors**: Ensure proper TLA+ syntax, correct operator usage, and valid module structure
1688 2. **Resolve runtime errors**: Define missing variables, operators, and ensure logical consistency
1689 3. **Maintain original intent**: Keep the core distributed system logic and behavior from the source code
1690 4. **Follow TLA+ best practices**: Use appropriate data structures, actions, and invariants
1691 5. **Be complete and self-contained**: Include all necessary EXTENDS, CONSTANTS, VARIABLES, and operator definitions
1692 ...
1693 Focus specifically on:
1694 - Defining any missing variables or constants
1695 - Implementing missing operators or functions
1696 - Fixing syntax issues with operators, expressions, or module structure
1697 - Ensuring proper action definitions and state transitions
1698 - Maintaining consistency with etcdraft's system behavior
1699 ...
1700 **CRITICAL OUTPUT REQUIREMENTS:**
1701 - Return ONLY pure TLA+ model code
1702 - NO markdown code blocks (no ```tla or ```)
1703 - NO explanations, comments, or text outside the model
1704 - NO formatting markers of any kind
1705 - The MODULE name must be exactly "etcdraft"
1706 - Start directly with: ---- MODULE etcdraft ----

```

H TRACE LEARNING AGENT

The trace learning agent does not use any code as input; instead, it relies on the distributed traces as context. Similar to the basic modeling agent, we provide an initial prompt analogous to the basic modeling agent’s prompt (§G.1), but substituting the codebase context with trace information instead. If the first model generation fails to pass compilation, the model refinement loop will pass the errors back to the LLM to iteratively fix the model.

Trace formats. The trace-based method works with several types of traces and can be easily extended to additional systems. For each trace format, we provide a short custom prompt explaining the format. We currently support:

- `.ndjson` and `.jsonl` logs: Newline-delimited JSON, with coarse-grained logs defined by the specific system. One log file contains multiple nodes’ execution logs.
- PGo-instrumented logs generated by TraceLink (Hackett & Beschastnikh, 2025): Also newline-delimited JSON and contains PGo-specific concepts like archetype names and vector clocks. Variable updates are logged in fine-grained detail at each PGo-defined critical section. One log file is output per node; there are multiple log files per distributed execution.

Optimizations. We anecdotally noticed that passing single execution traces results in overfitting by the model, with generated models closely reflecting the single executed path. Providing more traces improves context for the model.

One issue we encountered was fitting large traces into models’ context windows. The JSON structure of traces is expensive in tokens, because each “[”, “:”, and other punctuation represents a separate token. Most of the models we used had a context window of about 200K tokens; a JSON trace of several megabytes, such as the Etcd Raft traces, simply could not fit. We solved this with three workarounds:

- We support sampling for systems with large traces, randomly choosing a set of execution traces among all collected traces.
- We convert the nested JSON structure into tab-separated values (TSV) format, which deduplicates JSON keys into the TSV header and uses only tabs as a separator to save tokens.
- We abbreviate repeated state or action values (e.g., `ReceiveRequestVoteResponse`) to acronyms (e.g., `RRVR`) and provide a mapping in the prompt.

The TSV and abbreviation optimizations significantly save tokens: with the Claude tokenizer, it reduces token use by 62% for ten lines of Etcd Raft traces (from 645 to 262 tokens), and by 63% for ten lines of mutex traces (from 866 to 318 tokens). This enabled us to fit multiple traces into the initial prompt, reducing the impact of overfitting. We did not apply this optimization to the other methods, since code is less structured and does not have obvious candidates for deduplication.

I COMPLETE EVALUATION RESULTS

I.1 LIVENESS VIOLATION ANALYSIS

We analyzed counterexamples from two representative systems (Asterinas SpinLock and Etcd Raft) and categorized liveness violations into two main classes:

- *Fairness-related issues* that prevent progress due to missing fairness declarations, overly narrow or overly broad constraints (e.g., defined as $WF(Next)$);
- *Logical/structural issues* that block progress due to conflicting updates or missing/incorrect logic in action definitions.

Since the modeling task focuses on state/action models of the system implementation and LLMs are not required to generate temporal operators (e.g., in liveness properties), our categorization does not include errors related to temporal operators.

Table 12 presents the detailed breakdown of violations by category and LLM. For Asterinas SpinLock, fairness-related issues dominate the violations, particularly “too broad” and “too narrow” constraints. For instance, Claude-Sonnet-4, generated 26 out of 32 violations due to overly broad fairness assumptions.

For Etcd Raft, liveness violations are primarily caused by logical/structural issues. The model’s large state space causes these logical errors to block progress before fairness-related issues can manifest. Nevertheless, manual inspection confirms that fairness conditions are generally incorrect.

Table 12: Liveness violations by category in Asterinas SpinLock and Etcd Raft for the basic modeling agent.

(a) Asterinas SpinLock liveness violations by category

LLM	Fairness too broad	Fairness too narrow	Missing fairness	Logical errors	Total violations
Claude-Sonnet-4	26	2	4	0	32
GPT-5	8	10	2	0	20
Gemini-2.5-Pro	4	6	0	0	10
DeepSeek-R1	4	2	0	2	8

(b) Etcd Raft liveness violations by category

LLM	Logical missing/errors	Conflicting updates	Total violations
Claude-Sonnet-4	4	8	12
GPT-5	2	8	20
Gemini-2.5-Pro	0	0	0
DeepSeek-R1	4	4	8

I.2 DETAILED RESULTS BY SYSTEM

We present the complete evaluation results for all systems in our benchmark using three AI agents: Basic Modeling, Code Translation, and Trace Learning in Tables 13–23. These tables follow the same evaluation setup as described in §4.

Table 13: Asterinas Spinlock

Agent	LLM	Syntax	Runtime	Conformance	Invariant
Basic Modeling	Claude-Sonnet-4	100.00% ✓	100.00% ✓	100.00%	100.00%
	GPT-5	100.00% ✓	100.00% ✓	80.00%	100.00%
	Gemini-2.5-Pro	100.00% ✓	100.00% ✓	80.00%	85.71%
	DeepSeek-R1	100.00% ✓	100.00% ✓	80.00%	100.00%
Code Translation	Claude-Sonnet-4	100.00% ✓	100.00% ✓	100.00%	100.00%
	GPT-5	100.00% ✓	100.00% ✓	100.00%	85.71%
	Gemini-2.5-Pro	100.00% ✓	100.00% ✓	100.00%	100.00%
	DeepSeek-R1	100.00% ✓	100.00% ✓	100.00%	100.00%
Trace Learning	Claude-Sonnet-4	50.00% ✗	-	-	-
	GPT-5	100.00% ✓	0.00% ✗	-	-
	Gemini-2.5-Pro	100.00% ✓	0.00% ✗	-	-
	DeepSeek-R1	100.00% ✓	0.00% ✗	-	-

The trace learning agent underperforms compared to the other two agents, typically failing compilation and runtime checks. We observe that it is more difficult for LLMs to process structured trace data, in comparison to source code. Specifically, Claude-Sonnet-4 appears to be particularly weak in this regard, achieving the lowest syntax scores, despite its coding capabilities. This trend of the trace learning agent is consistent across all the evaluated system artifacts (Tables 14–23).

Table 14: Etcd Raft

Agent	LLM	Syntax	Runtime	Conformance	Invariant
