Paper under double-blind review

ABSTRACT

Attention mechanisms are central to the success of large language models (LLMs), enabling them to capture intricate token dependencies and implicitly assign importance to each token. Recent studies have revealed the sink token, which receives disproportionately high attention despite their limited semantic role. In this paper, we first expand the relationship between the sink token and other tokens, moving beyond attention to explore their similarity in hidden states, considering the layer depth. We observe that as the layers get deeper, the cosine similarity between the normalized hidden states of the sink token and those of other tokens increases, and that the normalized hidden states of the sink token exhibit negligible changes. These imply that other tokens consistently are directed toward the sink token throughout the layers. Next, we propose a dynamic token selection method, called OrthoRank, using these findings to select important tokens. Specifically, in a certain layer, we define token importance by the speed at which the token moves toward the sink token. This is converted into orthogonality with the sink token, meaning that tokens that are more orthogonal to the sink token are assigned greater importance. Finally, through extensive experiments, we demonstrated that our method results in lower perplexity and higher zero-shot accuracy compared to layer pruning methods at the same sparsity ratio with comparable throughput.

1 INTRODUCTION

Large language models (LLMs) have shown remarkable performance across various tasks 033 (Thirunavukarasu et al., 2023; Wu et al., 2024; 2023; Labrak et al., 2024; Nam et al., 2024) However, 034 despite this, the computational cost of LLM inference remains a significant challenge, especially for real-time applications. To address this challenge, many lightweight methods have been proposed for LLMs. Among the various methods, layer pruning is a simple and effective approach to reduce 036 computational costs by removing layers that have less impact on the model. The impact is quantified 037 by either measuring the similarity between the input and output at each layer (Siddiqui et al., 2024; Men et al., 2024), or by evaluating how the removal of a layer effects the final output (Song et al., 2024; Kim et al., 2024). Song et al. (2024) proposed an iterative pruning method based on these 040 metrics, while Kim et al. (2024) introduced a one-shot pruning approach followed by additional tun-041 ing using LoRA (Hu et al., 2022). However, these methods have a limitation. They rely on selecting 042 layers for pruning based on a calibration set, which statistically determines the layers that can be 043 bypassed without computation. As a result, they do not effectively reflect the specific characteristics 044 of the input tokens. For instance, at each layer, certain tokens may require computation while others do not, but layer pruning is unable to identify and process these tokens accordingly.

Motivated by the need for token level processing, early exit (Schuster et al., 2022; Chen et al., 2024) and mixture of depth (Raposo et al., 2024) have proposed dynamic computation paths based on token-level characteristics. Early exit determines that a token aligns with the final output, bypassing the remaining layers. Mixture of depth uses routers at each layer to decide whether a token should be computed or skipped. While these methods offer viable solutions, they rely on training additional routers or classifiers, or require the entire model to be trained specifically for early exit. Although these techniques have contributed to LLM acceleration, such as in speculative decoding, their practical use is limited because they require additional training across a wide range of existing models. This paper, therefore, begins by questioning:

Figure 1: Overview of our approach (OrthoRank). OrthoRank first determines the orthogonality of tokens to the sink token after normalization at each layer. Based on this, the top K tokens are selected for computation, while the remaining tokens bypass the layer.

Can we identify which tokens advantageous to compute at each layer without extra training?

072 To explore this, we analyze the internal workings of LLMs to determine whether each token requires 073 an update within a layer. Our focus is on one of the most distinctive phenomena in LLM behavior: the 074 attention sink (Xiao et al., 2024), which was first studied by investigating attention distributions and identifying the presence of attention sinks. This phenomenon shows that the initial token in an input 075 sequence receives a disproportionately large share of attention, despite often lacking meaningful 076 semantic value. This occurs because, in autoregressive models, the initial token is visible to nearly 077 all subsequent tokens, leading to 'excessive' attention scores. Since then, this phenomenon has been further explored (Sun et al., 2024; Cancedda, 2024), calibrated (Yu et al., 2024), and leveraged 079 in various ways (Son et al., 2024; Zhang et al., 2024) to improve LLM efficiency and enhance understanding of their mechanisms. Through further investigation, we observe that sink tokens and 081 other tokens exhibit a distinctive cosine similarity pattern (Section 2). 082

From this, we propose an importance ranking of tokens, OrthoRank, which leverages Or-083 thogonality to **Rank** tokens based on their relevance to the sink token. We confirm that selecting 084 tokens with our orthogonal-based importance is effective, as it outperforms the opposite method 085 in language modeling performance (Section 3.1). To apply this across multiple layers in the LLM, we adopt the layer evaluation method from layer pruning. We then replace each layer with a token 087 selection layer and evaluate them to identify the optimal token selection layers (Section 3.2). In Figure 1, we provide an overview of our proposed method, including the selection scheme. The main idea is to calculate each token's orthogonality to the sink token to select tokens. Selected tokens 090 pass through all steps within the layer (e.g., query, key, value, feed forward network, etc.), while 091 unselected tokens only participate in key and value calculations for the selected tokens without updating their own states, similar to early-exit mechanisms. Many studies (Sun et al., 2024; Son et al., 092 2024) suggest that in certain models, the attention sink phenomenon occurs not only with any token at the first position but also with specific delimiter tokens (e.g., ".", "\n"). However, for simplicity 094 and consistency, we focus our calculations on the first token. That is, h_i^l represents the input hidden 095 states of the sink token (i = 0) and other tokens $(i \ge 1)$ at layer l. 096

In summary, the key contributions of our paper are as follows:

- We discover that after the layer where the attention sink occurs, the cosine similarity between the normalized hidden states of the sink token and those of other tokens increases, as the layers deepen. However, the normalized hidden states of the sink token across the layers remains largely unchanged. These mean that other tokens are heading toward the sink token.
- We propose a simple but effective token selection method OrthoRank based on tokensink orthogonality, prioritizing tokens closer to orthogonality for computation and bypassing others, without the need for additional modules or training.
- We conduct extensive evaluations demonstrating that our method has better performance compared to the existing layer pruning at the same sparsity with comparable throughput.

2 FURTHER ANALYSIS ON ATTENTION SINK BEYOND ATTENTION

134 135

In this section, we revisit the concept of the attention sink and introduce new insights based on further analysis. An attention sink refers to the phenomenon where a particular token receives a disproportionately high amount of attention from other tokens. This phenomenon is always observed after a certain early layer, l_{sink} , in the initial token (Xiao et al., 2024; Sun et al., 2024).

We begin by verifying whether the special relationship between the sink token and the other tokens appears in states other than attention. To the best of our knowledge, we are the first to analyze the behavior of the sink token and other tokens through similarity analysis. In fact, the attention map provides limited information regarding the layers because there is little difference between the layers after layer l_{sink} . Therefore, we focus on the hidden states after the pre-attention normalization layer (i.e., the normalized hidden states), because they are the direct inputs for an attention module in each layer.

147 We investigate the cosine similarity between the normalized hidden states of tokens throughout the 148 layers, using wikittext dataset (Appendix F). Figures 2(a) and 2(d) describe the cosine similarity 149 between the normalized hidden states of the sink token (i.e., h_0) and those of other tokens (i.e., 150 h_i (1 $\leq i \leq 10$)) of Llama-2-13B and Mistral-7B, respectively. For each model, the attention sink 151 occurs at layer 4 and layer 2. It is observed that the cosine similarity between the sink token and other 152 tokens decreases drastically right after layer l_{sink} . However, after layer l_{sink} , the cosine similarity between the sink token and other tokens tends to increase as the layers progress, although the ranges 153 of cosine similarity vary across models. 154

These findings are simply illustrated in 3D by Figures 2(b-c) and 2(e-f). We plot each state as a unit vector on the hypersphere to focus on angles at layer right after l_{sink} and the final layer. In the subfigures, the red line represents the normalized hidden states of the sink token (i.e., h_0), while the blue lines represent those of other tokens (i.e., \bar{h}_1 and \bar{h}_{10}). Additionally, the cosine similarity between other tokens except for the sink token does not show any consistent trend, presented in Appendix B. In summary, our findings offer insights that go beyond the information derived from the attention map, revealing that as the layers deepen, the angles between the sink token and the other tokens gradually decrease, after layer l_{sink} .

Figure 3: (a-b) Cosine similarity between the normalized hidden states of the sink token across layers. (c-d) Cosine similarity between the normalized hidden states of another token (postiton 50) across layers. The red boundary represents the layers after layer l_{sink} . The sink token shows similar values not only with adjacent layers but also with distant layers, as confirmed through (a) and (b). In contrast, the another token show similarity in adjacent layers, but differences accumulate, leading to dissimilarity in distant layers, as shown in (c) and (d). These results highlight the static nature unique to the sink token, in contrast to other tokens.

Obs. (1). For layer l_{sink} and the final layer L, $cos(\bar{h}_0^{l_{sink}+1}, \bar{h}_i^{l_{sink}+1}) \leq cos(\bar{h}_0^L, \bar{h}_i^L), \forall i$. Moreover, when $l_{sink} < l_1 < l_2 \leq L$, it generally holds $cos(\bar{h}_0^{l_1}, \bar{h}_i^{l_1}) \leq cos(\bar{h}_0^{l_2}, \bar{h}_i^{l_2}), \forall i$.

Next, we explore the cosine similarity between the normalized hidden states of the same token across 185 different layers. Through this analysis, we can determine whether the sink token and other tokens 186 are converging towards each other, or if one remains relatively stationary while the other actively moves towards it. 187

188 Figures 3(a) and 3(b) illustrate the cosine similarity between the normalized hidden states of the sink 189 token across all layers of Llama-2-13B and Mistral-7B, respectively. The red boundary highlights 190 the layers ranging from l_{sink} to the final layer L. For Llama-2-13B, after passing through layer l_{sink} , 191 the layers are grouped together, with each group exhibiting a significantly higher degree of similarity 192 (close to 1). Despite this grouping, layers across different groups still maintain a relatively high level of similarity, approaching nearly 0.8. For Mistral-7B, all layers following layer l_{sink} form a single 193 cohesive group, where the similarity between these different layers is consistently close to 1. These 194 results suggest that the sink token experiences almost no change in its trajectory in the normalized 195 hidden states space as it moves through the deeper layers. Therefore, the *fixed* sink token on the 196 hypersphere in Figure 2, which simplifies our Observation (1), is nearly accurate. Furthermore, this 197 observation can be linked to massive activations of the sink token in the hidden states, which appear in a small number of fixed feature dimensions and are delivered to the next layer via the residual 199 connection, keeping high cosine similarity across layers. 200

Figures 3(c) and 3(d)illustrate the cosine similarity between the normalized hidden states of a token, 201 excluding the sink token, across all layers of Llama-2-13B and Mistral-7B, respectively. As ex-202 pected, due to the presence of residual skip connections, there is relatively high similarity between 203 adjacent layers, especially along the diagonal. However, as the model processes more layers, dif-204 ferences between the layers begin to accumulate, and the normalized hidden states at the final layer 205 eventually exhibit low cosine similarity compared to the normalized hidden states immediately fol-206 lowing layer l_{sink} . 207

> **Obs.** (2). When $l_{sink} < l_1 < l_2 \le L$, $cos(\bar{h}_0^{l_1}, \bar{h}_0^{l_2})$ remains close to 1. However, $cos(\bar{h}_i^{l_1}, \bar{h}_i^{l_2})$ decreases as the gap between l_1 and l_2 widens, $\forall i \ge 1$.

From Obs. (1) and Obs. (2), it is concluded that:

As the layers deepen, other tokens gradually align with the sink token, which remains almost static.

216 3 ORTHORANK: DYNAMIC TOKEN SELECTION

In this section, we extend our observations as criteria for selecting tokens at layer l (Section 3.1). Then, we propose a dynamic token selection algorithm, called OrthoRank (Section 3). Our algorithm can be used in conjunction with the layer selection algorithm.

3.1 DYNAMIC TOKEN SELECTION CRITERIA

Attention scores are widely used to identify relationships between tokens and are often employed to determine token importance. However, we discover that the relationships between tokens can also be captured through normalized hidden states. Based on this observation, we propose using these states to define token importance.

Our findings suggest that tokens follow a discrete trajectory in which they align with the sink token (i.e., they move in a direction that increases cosine similarity). Building on this, we define the importance of token i in a certain layer after l_{sink} as the extent to which token i can influence its cosine similarity with the sink token¹:

$$\left\|\frac{\partial}{\partial \bar{h}_i} \cos\left(\bar{h}_0, \bar{h}_i\right)\right\|. \tag{1}$$

(3)

Starting from the relation $\bar{h}_0^{\top} \bar{h}_i = \|\bar{h}_0\| \|\bar{h}_i\| \cos(\bar{h}_0, \bar{h}_i)$, we compute the gradient of $\cos(\bar{h}_0, \bar{h}_i)$ with respect to \bar{h}_i :

$$\frac{\partial}{\partial \bar{h}_i} \cos\left(\bar{h}_0, \bar{h}_i\right) = \frac{1}{\|\bar{h}_i\|} \left(\frac{\bar{h}_0}{\|\bar{h}_0\|} - \cos\left(\bar{h}_0, \bar{h}_i\right) \frac{\bar{h}_i}{\|\bar{h}_i\|}\right).$$
(2)

Assuming that normalized hidden states have approximately equal norms except for sink token, we can simplify the importance of token *i* based on the cosine similarity:

Thus, the importance of token *i* is directly related to how small $|\cos(\bar{h}_0, \bar{h}_i)|$ is. As $|\cos(\bar{h}_0, \bar{h}_i)|$ decreases, the importance increases because tokens that are **more orthogonal** to the sink token are more likely to be selected, as they have a greater potential to influence the overall cosine similarity.

 $\left\|\frac{\partial}{\partial \bar{h}_i}\cos\left(\bar{h}_0,\bar{h}_i\right)\right\|^2 \propto 1-\cos^2\left(\bar{h}_0,\bar{h}_i\right).$

For implementation convenience, since the norms are approximately equal, we use the absolute value of the inner product $|\bar{h}_0^{\top}\bar{h}_i|$ as a practical proxy for $|\cos(\bar{h}_0, \bar{h}_i)|$. Therefore, to select the top k important tokens, we rank them based on the smallest $|\bar{h}_0^{\top}\bar{h}_i|$, which corresponds to **selecting the tokens that are more orthogonal to the sink token**.

Select top k tokens with smallest
$$|\bar{h}_0^{\top}\bar{h}_i|$$
. (4)

To validate the effectiveness of our proposed selection criterion, we performed an experiment using the WikiText-2 dataset (Merity et al., 2022). In this experiment, we applied token selection one layer at a time, examining the impact on the model's language modeling performance. For each individual layer, we selected the top 33% of tokens for computation based on our proposed metric, which prioritizes tokens that are more orthogonal to the sink token (i.e., those with the smallest inner product). We then compared the resulting perplexity (ppl) scores to those obtained using an alternative method, where instead of selecting the most orthogonal tokens, we selected the bottom 33%—the tokens with the largest inner product—thereby evaluating the inverse of our approach.

¹For simplicity, l is omitted in this section.

Figure 4, shows the perplexity differences for layers after the attention sink (layer > 4), comparing our orthogonal token selection method to both reverse (green) and random selection (blue). The results demonstrate that our method consistently achieves lower perplexity, where a negative value indicates better performance (lower ppl) using our selection criterion, except in the final layer.

In summary, our orthogonal token selection criterion
leads to better performance across most layers, confirming its effectiveness in reducing computation while maintaining accuracy.

282 3.2 DYNAMIC TOKEN SELECTION WITH SELECTIVE283 LAYER

281

284

309

In Section 3.1, we demonstrated that selecting tokens closer to orthogonality at each layer improves effectiveness while preserving model performance. However, challenges arise when applying this selection across all layers. First, our selection criteria are less valid before the attention sink occurs. Second, layers near the output are crucial for maintaining model reliability and require computation for most tokens. Additionally, inter-layer dependencies must be considered.

Therefore, instead of applying our selection cri-290 teria (OrthoRank) across all layers, we pro-291 pose selectively applying it to specific lay-292 ers. To implement this, we combine our selec-293 tion criteria with existing layer pruning meth-294 ods. While traditional layer pruning approaches 295 measure performance by removing layers one 296 by one, we measure performance by applying 297 token selection to layers incrementally. This 298 strategy enables efficient computation across 299 both tokens and layers while preserving model fidelity. 300

301 Figure 5 compares layer pruning (Song et al., 2024) and OrthoRank with selective layers. In Figure 302 5(a), Layer pruning is applied to a Llama2-13b model with 40 layers and 20% sparsity, showing the 303 pruned layers. In Figure 5(b), to maintain the same sparsity, 30% of the layers are modified to 304 compute only 33% of the tokens, where the top 33% most orthogonal tokens to the sink token are 305 selected for computation. As shown in Figure 1, only the selected tokens are updated, while the remaining tokens bypass the computation by passing the output of the previous layer through the 306 residual path. Specifically, unselected tokens are excluded from query computation, the query input 307 to the attention mechanism, and the feed-forward network (FFN) computations. 308

4 EXPERIMENTS

4.1 IMPLEMENTATION DETAILS

We conducted experiments comparing layer pruning and OrthoRank with selective layer approaches. 352 Following the evaluation protocol in (Song et al., 2024), we set target sparsities at 10% and 20%. To 353 ensure the same sparsity ratio across methods, our algorithm applied 15% and 30% layer selection, 354 with only 33% of tokens computed in the selected layers. We compared our method against two 355 baseline algorithms: the iterative layer pruning method SLEB (Song et al., 2024) and the one-shot 356 pruning method Shortened LLaMA (Kim et al., 2024) without finetuning. Since the one-shot method 357 suffers a significant performance drop at 20% without fine-tuning, we limited its comparison to 10%358 sparsity. We measured throughput on a single A6000 GPU with a batch size of 32 and prompts of 359 length 2048. The throughput was averaged over 50. To validate the robustness of ours across a wide range of models, we conducted experiments on various models, including Llama2 (7B, 13B, 70B) 360 (Touvron et al., 2023), Llama3 (8B), Llama3.1 (70B) (Dubey et al., 2024), Mistral (7B) (Jiang et al., 361 2023), Mixtral (8×7B) (Jiang et al., 2024). Except for the ablation study on token selection ratio 362 (Section 4.5.4), all experiments were conducted with a ratio of 0.333. 363

- 364
- 4.2 RESULTS ON PERPLEXITY

366 Table 1 compares the performance of various models on the language modeling task. Since the lay-367 ers were pruned (selected) using the Wikitext-2 dataset, we used the the C4 validation set (Raffel 368 et al., 2020) for the performance comparison. Our proposed method, OrthoRank, outperformed other 369 layer pruning approaches in terms of perplexity in most cases except for some case of Mixtral-8x7B 370 model. This indicates that by focusing on token orthogonality to the sink token, OrthoRank effec-371 tively reduces computational complexity, achieving throughput improvements nearly proportional 372 to sparsity reductions—1.08x for 10% sparsity and 1.18x for 20%—demonstrating comparable efficiency to layer pruning. 373

374

375 4.3 RESULTS ON ZERO-SHOT TASK376

We further evaluated OrthoRank's performance on several zero-shot tasks, including PIQA (Bisk et al., 2020), WinoGrande (WG) (Sakaguchi et al., 2021), HellaSwag (HS) (Zellers et al., 2019),

 Table 4: Mean accuracies on LongBench for LlaMa-3-8B.

The evaluation results from LongBench (Bai et al., 2023) are shown in Table 4. For the Longbench experiments, we tested calibration lengths of 2048, 4096, and 8192 during the iterative layer selection process. As expected, higher context lengths led to improved performance, and OrthoRank consistently outperformed SLEB in most cases.

416 4.5 ABLATION STUDY

417 4.5.1 TOKEN SELECTION CRITERIA

Row 1, 2, and 5 in Table 3 compare the performance of different token selection strategies: random selection, Orthogonal ↓, and Orthogonal ↑ (Ours). Ours consistently achieves the best results, with lower perplexity and higher accuracy across all models, followed by random selection, while the opposite strategy (Orthogonal ↓) performs the worst. These results confirm that selecting tokens further from the sink token (Orthogonal ↑) leads to more efficient selection and improved performance for same computation complexity, validating the token selection criterion introduced in Section 3.

4.5.2 SIMILARITY MEASUREMENT STAGE

Table 3 compares the use of hidden states (Row 3) and normalized hidden states (Row 5) for token
selection. The results show that using normalized hidden states leads to better performance, with
lower perplexity and higher accuracy. As discussed in Section 2, our findings are based on normalized hidden states, making this result consistent with our expectations and further confirming the
importance of normalization in improving token selection. However, it performs better than some other components of our approach, suggesting that while the weights within the normalization pro-

Table 5: Ablation study according to the layer and token selection ratios under the sparsity of 20%.

Figure 6: Performance comparison across varying sparsity levels: (a) Log perplexity (lower is better) on C4 dataset and (b) Mean of zero-shot accuracies (higher is better) evaluated on PIQA, Wino-Grande, HellaSwag, ARC-Challenge, and ARC-Easy. OrthoRank demonstrates superior performance across all sparsity levels except at 0.4.

cess do affect the cosine similarity, the hidden state similarity still operates in a somewhat similar manner.

460 4.5.3 KV CALCULATION FOR UNSELECTED TOKENS

462 In Table 3, we compare Row 4, where Key and Value (KV) computations for unselected tokens 463 are skipped, with Row 5, where KV values are computed even for unselected tokens. The results show that calculating KV values for all tokens, regardless of whether they are selected for updates, 464 leads to better performance. This is because our token selection strategy focuses on how quickly a 465 token's state updates, without considering the influence these tokens exert on others through KV in-466 teractions. When KV calculations for unselected tokens are skipped, the reduced interaction among 467 tokens significantly degrades overall performance. Therefore, while unselected tokens are not up-468 dated, it is essential to compute their KV values to maintain model performance. This approach 469 resembles calculating key-value pairs for tokens that have exited in early exit methods. 470

- 471 472 4.5.4 Sparsity Trade-offs in Token and Layer Selection
- We conducted experiments by varying the ratio of selected layers and selected tokens while maintaining the same effective sparsity. Based on Table 5, we recommend using a token selection ratio
 between 0 and 0.5.

477 4.5.5 PERFORMANCE COMPARISON ACROSS SPARSITY LEVELS478

Figure 6 compares OrthoRank's performance under varying sparsity levels using log perplexity on
the C4 dataset (Figure 6a) and mean accuracy on zero-shot tasks (Figure 6b). OrthoRank consistently
achieves lower perplexity than SLEB across all sparsity levels except 40%, demonstrating its ability
to optimize token selection while preserving language modeling capabilities.

In zero-shot tasks, OrthoRank also outperforms other methods across most sparsity levels, except at 40%, where performance parity is observed. These results highlight the effectiveness of token orthogonality-based selection in balancing computational efficiency and model accuracy across diverse tasks.

486 5 **RELATED WORK**

487 488

Layer Pruning. Layer pruning has been a prominent approach for reducing the computational 489 complexity of large language models (LLMs), particularly in transformer architectures (Siddiqui 490 et al., 2024; Men et al., 2024). Approaches like SLEB (Song et al., 2024) and Shortened LLaMA 491 (Kim et al., 2024) aim to remove entire layers that are deemed less critical for downstream tasks. 492 These methods often rely on performance metrics or sensitivity analysis to determine which layers contribute less to overall model accuracy and can be pruned without significant loss of performance. 493 However, layer pruning may result in abrupt performance degradation, particularly when layers <u>191</u> responsible for essential token transformations are removed. While these methods effectively reduce 495 model depth, they do not account for token-level variations within layers. In contrast, our approach 496 integrates token selection within specific layers, maintaining layer depth but reducing the number 497 of tokens processed in each layer, thus offering a more fine-grained control over computational 498 efficiency. 499

500 **Attention Sink.** The concept of the attention sink, where certain tokens receive disproportionately 501 high attention across layers, has gained attention in recent studies. Xiao et al. (2024) first introduced 502 the term "attention sink" to describe how the initial token in a sequence tends to dominate attention 503 scores in autoregressive models. This is attributed to its visibility to all subsequent tokens, causing it 504 to act as a "sink" for attention. Sun et al. (2024) further investigated the attention sink phenomenon, 505 showing that this behavior persists across multiple layers, leading to a static role for the sink token, while other tokens move toward it in hidden state space. Building on these observations, our work 506 explores token-sink orthogonality and uses this metric to inform token selection. By selecting tokens 507 that are more orthogonal to the sink token, we prioritize tokens with greater potential to contribute to 508 meaningful computations, leveraging the inherent token dynamics to optimize inference efficiency. 509

510

Token Pruning. Token pruning methods have been widely explored as a way to reduce the number 511 of tokens processed across layers, thus decreasing computational load. Techniques like dynamic to-512 ken selection (Lou et al., 2024) and early exit mechanisms (Chen et al., 2024; Del Corro et al., 2023; 513 Elhoushi et al., 2024) progressively drop tokens deemed uninformative as they pass through layers. 514 These methods rely on criteria such as attention scores or token contribution measures to decide 515 which tokens to prune. However, one potential downside of token pruning is the loss of potentially 516 relevant information as tokens are eliminated layer by layer, especially in deeper models where re-517 maining tokens may not fully capture the complexity of the input sequence. Our approach differs 518 significantly in that we do not progressively drop tokens across layers. Instead, we selectively compute a subset of tokens at specific layers based on their orthogonality to the sink token. This ensures 519 that we preserve the flexibility to compute tokens based on their relevance without completely dis-520 carding them, thus mitigating the risk of information loss while still reducing computational costs. 521

522 523

524

6 CONCLUSION

525 In this paper, we introduced OrthoRank, a dynamic token selection strategy based on the orthogo-526 nality between tokens and the sink token. Our approach was motivated by the observation that as layers deepen, tokens increasingly align with the sink token in the normalized hidden state space. 527 By analyzing token-sink similarity, we found that tokens more orthogonal to the sink token play 528 a greater role in computation. Leveraging this insight, we developed a token selection mechanism 529 that prioritizes such tokens at specific layers, leading to more efficient computation. By applying 530 this token selection approach to selective layers, we achieved superior performance compared to 531 traditional layer pruning methods at the same sparsity level with comparable throughput. Extensive 532 experiments demonstrated significant improvements, and ablation studies confirmed that our selec-533 tion scheme is optimized both theoretically and empirically. Furthermore, our findings on token-sink 534 similarity offer valuable insights for future research in Efficient LLM inference and Interpretable 535 LLMs, providing a foundation for further optimizing and understanding large language models.

В COSINE SIMILARITY CHANGES BETWEEN TOKENS ACROSS LAYERS

Figure 8: Cosine similarity changes between tokens across layers. Each column corresponds to a different model: Llama-2-7B, 13B, 70B; Meta-Llama-3-8B; and Llama-3.1-70B. Left: Cosine simi-805 larity between tokens at position 0 and 91–100. Right: Cosine similarity between tokens at position 806 50 and 91-100. Results highlight tokens show increasing cosine similarity with the sink token (position 0) across layers (left), but show no consistent trend with position 50 (right). 808

809

807

Under review as a conference paper at ICLR 2025

Figure 9: Cosine similarity changes between diverse tokens across layers. Each column corresponds to a different model: Llama-2-7B, 13B, 70B; and Meta-Llama-3-8B. Left: Cosine similarity between tokens at position 0 and {1, 10, 100, 1000}. Right: Cosine similarity between tokens at position at position 50 and {1, 10, 100, 1000}. Results highlight that tokens, even when their positions are far from each other, show increasing cosine similarity with the sink token (position 0) across layers (left), but show no consistent trend with position 50 (right).

C SUPPLEMENTARY DERIVATION FOR SECTION 3

We begin with the gradient of the cosine similarity between the sink token's hidden state \bar{h}_0 and the hidden state of token i, \bar{h}_i

$$\frac{\partial}{\partial \bar{h}_i} \cos\left(\bar{h}_0, \bar{h}_i\right) = \frac{1}{\|\bar{h}_i\|} \left(\frac{\bar{h}_0}{\|\bar{h}_0\|} - \cos\left(\bar{h}_0, \bar{h}_i\right) \frac{\bar{h}_i}{\|\bar{h}_i\|}\right).$$
(5)

We are interested in the magnitude of this gradient, specifically its squared norm:

$$\left\|\frac{\partial}{\partial\bar{h}_i}\cos\left(\bar{h}_0,\bar{h}_i\right)\right\|^2 = \frac{1}{\|\bar{h}_i\|^2} \left\|\frac{\bar{h}_0}{\|\bar{h}_0\|} - \cos\left(\bar{h}_0,\bar{h}_i\right)\frac{\bar{h}_i}{\|\bar{h}_i\|}\right\|^2 \tag{6}$$

As observed in Figure 9, the norms of the hidden states $\|\bar{h}_i\|$ (excluding $\|\bar{h}_0\|$) are approximately equal. Therefore, we assume:

_

$$|\bar{h}_i|| \approx c \tag{7}$$

Substituting $\|\bar{h}_i\| \approx c$ into the gradient norm squared:

$$\left\|\frac{\partial}{\partial \bar{h}_i}\cos(\bar{h}_0,\bar{h}_i)\right\|^2 \approx \frac{1}{c^2} \left\|\frac{\bar{h}_0}{\|\bar{h}_0\|} - \cos(\bar{h}_0,\bar{h}_i)\frac{\bar{h}_i}{c}\right\|^2 \tag{8}$$

_

To simplify the expression, we define unit vectors \mathbf{u}, \mathbf{v} as follows:

$$\mathbf{u} = \frac{h_0}{\|\bar{h}_0\|}, \quad \mathbf{v} = \frac{h_i}{c} \tag{9}$$

Substituting **u** and **v** into the expression:

$$\left\|\frac{\partial}{\partial \bar{h}_i} \cos(\bar{h}_0, \bar{h}_i)\right\|^2 \approx \frac{1}{c^2} \left\|\mathbf{u} - \cos(\mathbf{u}, \mathbf{v})\mathbf{v}\right\|^2$$
(10)

We compute the squared norm:

$$\|\mathbf{u} - \cos(\mathbf{u}, \mathbf{v})\mathbf{v}\|^2 = \|\mathbf{u}\|^2 - 2\cos(\mathbf{u}, \mathbf{v})\mathbf{u}^\top \mathbf{v} + \cos^2(\mathbf{u}, \mathbf{v})\|\mathbf{v}\|^2$$
$$\approx 1 - 2\cos^2(\mathbf{u}, \mathbf{v}) + \cos^2(\mathbf{u}, \mathbf{v})$$
$$= 1 - \cos^2(\mathbf{u}, \mathbf{v})$$

Substituting back:

$$\left\|\frac{\partial}{\partial \bar{h}_i}\cos(\bar{h}_0,\bar{h}_i)\right\|^2 \approx \frac{1}{c^2} \left(1 - \cos^2(\bar{h}_0,\bar{h}_i)\right) \tag{11}$$

Since $\frac{1}{c^2}$ is a constant, the gradient norm squared is proportional to $1 - \cos^2(\bar{h}_0, \bar{h}_i)$:

$$\left\|\frac{\partial}{\partial\bar{h}_i}\cos(\bar{h}_0,\bar{h}_i)\right\|^2 \propto 1 - \cos^2(\bar{h}_0,\bar{h}_i)$$
(12)

Figure 10: Norms of the normalized hidden states. This figure plots the norms of the normalized hidden states $\|\bar{h}_i\|$ for various token positions in the sequence. The red line represents the norm of the hidden state at position 0 (the sink token), while the blue lines correspond to the norms of the hidden states at positions 91 to 100. The plot illustrates that the norms of the hidden states (excluding the sink token) are approximately equal.

972 D LAYER-WISE RESULTS 973

Figure 11 shows the perplexity differences for layer-wise manner, comparing our orthogonal token
selection method to both reverse (green) and random selection (blue). OrthoRank demonstrated
superior performance compared to both Random and Reverse (opposite) approaches in most models
and across most layers. Rare layers where OrthoRank performs worse are automatically filtered out
during the selection process, so this does not pose a significant issue.

1026 E RESULTS FOR EACH TASK

In this section, we present the detailed results for each task corresponding to Table 1, Table 2, and Table 4 in the main paper.

Table 6: Zero-shot results (%) for various tasks and models with SLEB and OrthoRank by sparsity.

Model	Sparsity	Method	PIQA	WG	HS	ARC-C	ARC-E

This section provides the input text used to generate the plots in Figures 2, 3, 7, and 8. Due to memory constraints associated with storing token hidden states for visualization, we limited the context length to 101 tokens. The following text is extracted as the first 101 tokens from the test split of WikiText-2-raw-v1. For clearer visualization, we excluded n, which is known to cause additional attention sink (Sun et al., 2024), from the experiments.

1088 = Robert Boulter = Robert Boulter is an English film, television and theatre actor. He had a guest @-@ starring role on the 1089 television series The Bill in 2000. This was followed by a starring role in the play Herons written by Simon Stephens , which was 1090 performed in 2001 at the Royal Court Theatre . He had a guest role in the television series Judge John Deed in 2002 . In 2004 Boulter 1091 landed a role as "Craig" in the episode "Teddy 's Story" of the television series The Long Firm ; he starred alongside actors Mark Strong and Derek Jacobi . He was cast in the 2005 theatre productions of the Philip Ridley play Mercury Fur , which was performed 1093 at the Drum Theatre in Plymouth and the Menier Chocolate Factory in London . He was directed by John Tiffany and starred alongside Ben Whishaw, Shane Zaza, Harry Kent, Fraser Ayres, Sophie Stanton and Dominic Hall. In 2006, Boulter starred 1094 alongside Whishaw in the play Citizenship written by Mark Ravenhill . He appeared on a 2006 episode of the television series , 1095 Doctors , followed by a role in the 2007 theatre production of How to Curse directed by Josie Rourke . How to Curse was performed at Bush Theatre in the London Borough of Hammersmith and Fulham . Boulter starred in two films in 2008, Daylight Robbery by filmmaker Paris Leonti , and Donkey Punch directed by Olly Blackburn . In May 2008 , Boulter made a guest appearance on a two @-@ part episode arc of the television series Waking the Dead , followed by an appearance on the television series Survivors in 1099 November 2008. He had a recurring role in ten episodes of the television series Casualty in 2010, as "Kieron Fletcher". Boulter 1100 starred in the 2011 film Mercenaries directed by Paris Leonti . = = Career = = = = 2000 - 2005 = = = In 2000 Boulter had a 1101 guest @-@ starring role on the television series The Bill ; he portrayed " Scott Parry " in the episode , " In Safe Hands " . Boulter 1102 starred as "Scott" in the play Herons written by Simon Stephens , which was performed in 2001 at the Royal Court Theatre . A 1103 review of Boulter's performance in The Independent on Sunday described him as "horribly menacing" in the role, and he received 1104 critical reviews in The Herald, and Evening Standard. He appeared in the television series Judge John Deed in 2002 as "Addem Armitage " in the episode " Political Expediency ", and had a role as a different character " Toby Steele " on The Bill . He had a 1105 recurring role in 2003 on two episodes of The Bill, as character " Connor Price ". In 2004 Boulter landed a role as " Craig " in 1106 the episode "Teddy 's Story" of the television series The Long Firm ; he starred alongside actors Mark Strong and Derek Jacobi . 1107 Boulter starred as "Darren", in the 2005 theatre productions of the Philip Ridley play Mercury Fur . It was performed at the Drum 1108 Theatre in Plymouth , and the Menier Chocolate Factory in London . He was directed by John Tiffany and starred alongside Ben 1109 Whishaw, Shane Zaza, Harry Kent, Fraser Ayres, Sophie Stanton and Dominic Hall. Boulter received a favorable review in The 1110 Daily Telegraph : "The acting is shatteringly intense, with wired performances from Ben Whishaw (now unrecognisable from his 1111 performance as Trevor Nunn's Hamlet), Robert Boulter, Shane Zaza and Fraser Ayres." The Guardian noted, "Ben Whishaw 1112 and Robert Boulter offer tenderness amid the savagery ." = = 2006 - present = = In 2006 Boulter starred in the play Citizenship 1113 written by Mark Ravenhill . The play was part of a series which featured different playwrights , titled Burn / Chatroom / Citizenship 1114 . In a 2006 interview , fellow actor Ben Whishaw identified Boulter as one of his favorite co @-@ stars : " I loved working with a 1115 guy called Robert Boulter , who was in the triple bill of Burn , Chatroom and Citizenship at the National . He played my brother 1116 in Mercury Fur . "He portrayed "Jason Tyler" on the 2006 episode of the television series , Doctors , titled "Something I Ate". Boulter starred as "William" in the 2007 production of How to Curse directed by Josie Rourke . How to Curse was performed at 1117 Bush Theatre in the London Borough of Hammersmith and Fulham. In a review of the production for The Daily Telegraph, theatre 1118 critic Charles Spencer noted, " Robert Boulter brings a touching vulnerability to the stage as William . " Boulter starred in two 1119 films in 2008, Daylight Robbery by filmmaker Paris Leonti, and Donkey Punch directed by Olly Blackburn. Boulter portrayed a 1120 character named "Sean" in Donkey Punch, who tags along with character "Josh" as the "quiet brother ... who hits it off with 1121 Tammi". Boulter guest starred on a two @-@ part episode arc" Wounds" in May 2008 of the television series Waking the Dead 1122 as character "Jimmy Dearden". He appeared on the television series Survivors as "Neil" in November 2008. He had a recurring 1123 role in ten episodes of the television series Casualty in 2010, as "Kieron Fletcher". He portrayed an emergency physician applyi 1124

G EXPLORING THE TRADE-OFFS BETWEEN THROUGHPUT AND PERPLEXITY

In this section, we investigated the relationship between throughput improvements and perplexity across varying sparsity levels. Figure 12 demonstrates how each point corresponds to a specific sparsity level. A sharp increase in perplexity is observed at the 50% sparsity point, highlighting the critical threshold for balancing sparsity and preserving model performance while accounting for the speed tradeoff. Based on this finding, we recommend using OrthoRank with sparsity levels below 40% to maintain an optimal balance.

Figure 12: The relationship between throughput improvements and perplexity (C4). Each point represents a different sparsity level, showing a sharp increase in perplexity at the 50% sparsity level
