Breaking Language Barriers in Multilingual Mathematical Reasoning: Insights and Observations

Anonymous ACL submission

Abstract

Existing research predominantly focuses on 001 developing powerful large language models (LLMs) for mathematical reasoning within monolingual languages, with few explorations in preserving efficacy in a multilingual con-006 text. To bridge this gap, this paper pioneers exploring and training powerful Multilingual Math Reasoning (xMR) LLMs. Firstly, by utilizing translation, we construct the first multilingual math reasoning instruction dataset, MGSM8KInstruct, encompassing ten distinct languages, thus addressing the issue of training data scarcity in xMR tasks. Based on the collected dataset, we propose different training strategies to build powerful xMR LLMs, 016 named MathOctopus, notably outperform conventional open-source LLMs and exhibit su-017 periority over ChatGPT in few-shot scenarios. Notably, MathOctopus-13B reaches 47.6% accuracy which exceeds ChatGPT 46.3% on MGSM testset. Beyond remarkable results, we unearth several pivotal observations and in-022 sights from extensive experiments: (1) When extending the rejection sampling strategy to the multilingual context, it proves effective for model performances, albeit limited. (2) Employing parallel corpora for math Super-027 vised Fine-Tuning (SFT) across multiple languages not only significantly enhances model performance multilingually but also elevates their monolingual performance. This indicates that crafting multilingual corpora can be regarded as a vital strategy for enhancing model performance in a specific language, especially in mathematical reasoning tasks. For instance, MathOctopus-7B improves its counterparts that trained on English from 42.2% to 037 50.8% on GSM8K testset.

1 Introduction

042

Large language models (LLMs) (Brown et al., 2020; Hu et al., 2021; Zeng et al., 2022; OpenAI, 2023; Scao et al., 2022) such as Bloom (Scao et al.,

2022) and GPT4 (OpenAI, 2023) have exhibited remarkable performances across a wide array of downstream tasks. Notwithstanding these significant advancements, even the most extensive LLMs are confronted with challenges when faced with mathematical reasoning tasks that necessitate multiple reasoning steps (Gao et al., 2023). 043

Many recent works focus on using different prompting methods like chain-of-thought (CoT) to solve mathematical problems based on closesourced LLMs such as ChatGPT and GPT-4. Significantly, LLaMA-Family models (Touvron et al., 2023a,c) have ignited an open-source movement and rapidly reduced the disparity with these closedsource LLMs. Following the line, Yuan et al. (2023a) apply rejection sampling fine-tuning (RFT) for math reasoning LLMs. WizardMath (Luo et al., 2023) advance mathematical reasoning in LLMs through Reinforcement Learning from Evol-Instruct (RLEIF). However, current efforts are primarily focusing on improving the performance of LLMs in English. Although, Shi et al. (2022) propose MGSM testset to explore multilingual math reasoning through in-context learning, training a powerful multilingual mathematical reasoning LLM remains under-explored.

To this end, this paper empirically investigates and enhances the multilingual mathematical reasoning abilities of current open-source LLMs such as LLaMA through supervised learning. Given mathematical problems from different languages, we aspire one single model to correctly answer questions in the respective target language, not just limited to English. However, when scaling out mathematical reasoning to multiple languages, i.e., the task of multilingual mathematical reasoning or **xMR** for short, one main challenge is the training data scarcity in low-resource languages, where no training examples are available. To tackle this challenge, we begin by using ChatGPT to translate the English GSM8K math training dataset into 9 vari-

Figure 1: Multilingual Math Instruction Tuning of MathOctopus.

ous languages. Concurrently, we employ specific rules to calibrate and align the translated corpora, ensuring the data quality.

The resulting data are used to construct our multilingual math instruction training dataset: MGSM8KInstruct, which encompasses instructional data within two distinct settings: Paralleltraining and Cross-training. The Parallel-training setting denotes that both the mathematical queries and the CoT answers derive from the same language. Conversely, the Cross-training setting indicates that the questions are in English, while the corresponding answers are in other languages. The objective of these settings is to develop LLMs are capable of solving mathematical problems coherently, whether presented in English or other target languages, while ensuring adaptability and maintaining rigorous mathematical reasoning across multiple languages. Step further, to conduct a more exhaustive and comprehensive evaluation of the model's multilingual mathematical capabilities, we additionally develop an out-of-domain xMR testset: MSVAMP, incorporating 10 languages, based on SVAMP (Patel et al., 2021). This construction involves the employment of machine translation, further refined by meticulous manual calibration.

We then use MGSM8KInstruct to supervise finetune (SFT) current open-source LLMs including LLaMA-Families ranging from 7B to 33B, as shown in Figure 1. Following training, the models demonstrate exemplary abilities in xMR tasks. We name the resulting models as MathOctopus, attributing their adaptability and extensive proficiency in xMR tasks across a variety of languages. 117 118 For example, MathOctopus -7B improves the average performance of LLaMA2-7B on the MGSM 119 dataset across ten languages from 22.6% to 40%. 120 Surprisingly, compared with LLMs trained on the 121 monolingual corpus, MathOctopus also shows su-122

perior performances when tested in their respective training languages. For instance, MathOctopus-7B elevate the accuracy of LLaMA2-7B on the English GSM8K from 42.3% to 50.8%. We posit that this improvement is attributable to the enhanced generalization capability of the model acquired during multilingual training, as well as the reasoning knowledge learned from other languages feeding back into in English.

Subsequently, we delve into an exploration of the influences of SFT data volumes and diverse reasoning paths on the efficacy of the SFT model in multilingual context. Inspired by (Yuan et al., 2023a), we apply multilingual rejection sampling on MathOctopus to generate different correct reasoning paths as an augmented training corpus. By incorporating this data into our prior MGSM8KInstruct for fine-tuning LLMs, we observe limited enhanced multilingual mathematical reasoning outcomes. We term this training approach Multilingual Rejection Sampling Finetuning (xRFT). Experimentally, xRFT can further elevate the LLM's xMR outcomes, but it may potentially compromise the model's generalization ability as the data amount increases.

In summary, our contributions are as follows:

- We construct MGSM8KInstruct, a first multilingual math reasoning instruction dataset. Subsequently, MSVAMP, an out-of-domain multilingual mathematical reasoning dataset, is collected, serving as a robust test bed to further assess the robustness of LLMs.
- Based on collected data and different training strategies, we build a series of powerful LLMs MathOctopus in xMR tasks. Our model not only significantly improves its reasoning capabilities in low-resource languages compared 159

- 160to LLaMA but also greatly enhances its per-161formance in English.
- We explore the relationship between model performance and data volume, as well as the impact of different training strategies. One of the most surprising observation is that multilingual SFT could be regarded as a crucial strategy for enhancing mathematical reasoning proficiency in LLMs.

In this section, we aim to illustrate our method in detail. We first review the problem formulation of multilingual mathematical reasoning. Then we describe the collection process of MGSM8KInstruct and MSVAMP datasets. Subsequently, we present our proposed MathOctopus and multilingual rejection sampling methods, sequentially.

2.1 Problem Formulation

Commonly, the mathematical reasoning problemsolving task can be defined as $\mathcal{D} = \{Q_i, O_i, A_i\}$, where Q_i is the target math question, $O = \{O_1, O_2, ..., O_k\}$ are answer options if Q_i is a Kway multiple choice problem, A_i is the corresponding ground-truth answer. Given Q_i as inputs, LLMs can directly output answers or a sequence of tokens as intermediate reasoning steps R_i via CoT. Then we can obtain the answer in R_i through regular expression matching.

In this work, we extend mathematical reasoning tasks from monolingual to multilingual contexts: \mathcal{D}_{en} to $\mathcal{D}_{en}...\mathcal{D}_{zh}$. We aspire to enable only one model to successfully solve mathematical problems presented in various languages. That is, given $Q_{i(zh,es,...)}$ in a target language like Chinese, Spanish and etc, the model can furnish correct CoT responses $R_{i(zh,es,...)}$ in a specific language, even when the problems are solely presented in English.

2.2 MGSM8KInstruct

Source Data Prior to going further, the main concern in xMR is data scarcity of the multilingual training corpus. We employ GSM8K (Cobbe et al., 2021), an English dataset comprised of middle grade-school mathematical problems annotated by humans, as our fundamental data source. According to the officially provided solutions, each problem in GSM8K necessitates a resolution process involving between two to eight steps. **Target Languages** As for target languages in translation, we choose a set of ten languages that are typologically varied from English (En), covering different language families. Similar with (Shi et al., 2022), the ensemble of languages incorporated in this study comprises Bengali (Bn), Chinese (Zh), French (Fr), German (De), Japanese (Ja), Russian (Ru), Spanish (Es), Swahili (Sw), and Thai (Th). This diverse conglomerate facilitates an exhaustive exploration into the model's adaptability and proficiency amidst divergent linguistic architectures and typologies.

Translation Process Given the reliability and applicability of ChatGPT for translation tasks, we utilize ChatGPT to translate 7473 problems and CoT responses from the English GSM8K training set and their corresponding CoT answers into the target languages. To ensure the quality and consistency of the translations, we adopt the following strategies within the translation prompts:

- 1. Maintain consistent translations for names of people and places within the sentences.
- 2. Preserve the mathematical formulas during translation.
- 3. All numbers must be represented using Arabic numerals to facilitate cross-lingual prediction.
- 4. To pursue more accurate translations, we provide two translation examples in the prompts for each language.

Verify Strategy Upon inspection of our randomly sampled translations, we find that ChatGPT generally maintains semantic accuracy in translations; however, discrepancies in formula translations may arise. Thus, to uphold consistency and accuracy across multiple languages, we additionally extract all formulas present in the translated answers. If all formulas are calculated correctly and are consistent with those in English, we deem the translation to be accurate and error-free. Note that if errors persist across 5 consecutive translations, we discard that particular case.

This approach ensures a coherent and accurate translation process, allowing for comprehensive evaluation and application in xMR tasks while maintaining linguistic and mathematical integrity. Upon acquiring the translated data, by pairing it with the alpaca-format prompts, we are able to formulate our final training dataset MGSM8KInstruct,

Dataset	En	Sw	Zh	Bn	De	Es	Fr	Ja	Ru	Th	Overall

Training Strategies We then use multilingual query-response pairs in MGSM8KInstruct to supervise fine-tune LLMs, resulting in MathOctopus. As illustrated before, let us delve into a detailed exposition of our diverse training strategies:

- *Parallel-training*, involves filling in the input prompts with questions and answers in the same native language during training. This strategy is like teaching the model to communicate clearly in one language at a time. It helps the model get better at answering questions accurately within the same language, making it more reliable and effective.
- Cross-training, refers to our approach during training where we insert English questions and answers in one native language into the input prompts. This approach is like mixing languages in teaching, using English questions and native language answers. It helps the model understand and connect different languages better, making it more versatile and capable of handling multilingual scenarios.

Multilingual Rejection Sampling Prior work 281 (Yuan et al., 2023a) has demonstrated that LLM's performance can be further enhanced by augment-283 ing data through rejection sampling (RFT). Consequently, in this paper, we explore whether the gains imparted by RFT persist in multilingual scenarios. 287 After obtaining the preliminary SFT model, we perform multiple inferences with the SFT model in the 288 MGSM8KInstruct dataset, sampling more diverse and accurate reasoning paths from different languages to integrate into the original dataset. More 291

specifically, we first eliminate samples with incorrect final answers. Subsequently, we extract all the formulas in each reasoning path and validate their accuracy; if all are correct, we consider that reasoning path as correct. We then follow the strategies from (Yuan et al., 2023a) to acquire different correct reasoning paths: a reasoning path is only collected as augmented data if no previously collected path contains identical formulas.

However, the reasoning paths sampled from one single SFT model can be logically non-diverse. Consequently, we anticipate further enhancing the mathematical reasoning performance by leveraging reasoning paths aggregated from different models via multilingual rejection sampling. Considering the cost of prolonged inference, we currently perform 25 inferences for each language from the basic MathOctopus 7B and 13B models respectively, meaning we sample answers for each question in every language 50 times. In our experiments, we fuse all the different reasoning paths generated by the two models to obtain our final xRFT augmented data. We set the temperature as 0.9 and with different seeds to expect the model to generate diverse solutions. The table 2 displays the number of different reasoning paths per question produced in each language over 50 samples.

3 Experiments

In this section, we first review our in-domain evaluation dataset: MGSM, and the collection of the out-of-domain testset: MSVAMP. Subsequently, we introduce multiple baselines in this work. At last, we present the main results and findings of our experiments. We illustrate our experimental setup for training and testing in Appendix B.

3.1 Evaluation Datasets

MGSM The source data of MGSM (Shi et al., 2022) is collected from a subset from GSM8K testset, and then native annotators translate the subset in English into other 10 languages. Each language branch consists of 250 test samples.

MSVAMP We choose SVAMP as our English 333 source data. Given that the answers in the SVAMP 334

Close-Source LLMs In this paper, We con-345 sider two OpenAI's LLMs: GPT-4 and ChatGPT (gpt3.5-turbo) for comparison: (1) We test Chat-GPT with zero-shot prompting where none exemplars are given, but we add "Let's think step by step." at the end of the inputs. (2) As Shi et al. (2022) proves including EN-CoT examples could result in better performances in xMR tasks, we additionally test them with 2 shot EN-coT examples, 353

which are shown in Appendix Table 10.

Open-Source LLMs For fairness, we primarily compare MathOctopus with several LLaMA-based models, including LLaMA base, RFT, MAmmoTH and WizardMath. In this work, LLaMA base denotes trained on GSM8K English corpus; RFT utilizes rejection sampling on English instruction tuning; MAmmoTH is trained based on a variety of math instruction datasets; WizardMath is built on Reinforcement Learning from Evol-Instruct (RLEIF) in math reasoning. As we only consider CoT solutions in this work, we don't use the code version of these models.

$\begin{array}{l} {\tt MathOctopus}^{\mathcal{P}}\mbox{-}33B\\ {\tt MathOctopus}^{\mathcal{C}}\mbox{-}33B \end{array}$	46.5 53.3	46.6 49.4					

Table 5: Average performances of MathOctopus^C and MathOctopus^{\mathcal{P}} under the *Cross-Test* settings.

LLMs struggle in xMR tasks, especially in low-374 resource languages. From the tables, current open-source LLMs still suffer in xMR in terms of in-domain and out-of-domain testing. For instance, LLMs with 7B-level only achieve about 20%-23%

accuracy in MGSM. Another conspicuous observation is the stark performance contrast of existing models when dealing with high-resource versus low-resource languages. This discrepancy can be largely attributed to the diminutive representation of low-resource languages in their foundational corpus. In contrast, our model adeptly rectifies this shortcoming, as evidenced by its enhanced performance in languages like Thai and Swahili.

396

Performance Superiority of MathOctopus. The proposed MathOctopus, whether in cross-training or parallel-training, both significantly outperforms other open-source LLMs by a large margin. For instance, when operating at the 7B-level, our model can boost the LLaMA model's efficacy from a mere 22.6% to a commendable 41.9% on MGSM. Furthermore, this superiority still remains as the model size escalates. Surpris-

372

ingly, MathOctopus^P-13B even surpasses Chat-GPT on MGSM. Another interesting finding is that MathOctopus \mathcal{P} performs better in the in-domain test while MathOctopus^C shows better generalization ability in the out-of-domain test, proving their unique advantages, separately.

Table 6: Model performances on English datasets.

Marginal Impact of xRFT. The xRFT's contribution to model enhancement appears to be somewhat circumscribed. Its potency wanes, particularly in out-of-domain test scenarios. In tests within MGSM, the xRFT's contribution to MathOctopus^{\mathcal{P}} hovers around a modest 1%-2% average uplift. However, this figure dips below 1% in MSVAMP testset. More intriguingly, the augmentative effect of xRFT on MathOctopus^C seems even more subdued, with potential performance deterioration observable on the MGSM.

3.3.1 **Training-Testing Consistencies**

As shown in the tables, equally significant is the discernible performance disparity between models employing MathOctopus^C versus MathOctopus^P, when subjected to the same quantum of training data: MathOctopus $^{\mathcal{P}}$ leads to better in-domain test performances compared with MathOctopus^C. A deeper delve into this phenomenon revealed an incongruity between the training and testing environments. Specifically, in the MGSM and MSVAMP testsets, the data adheres to a parallel structure, where both the query and its corresponding response are couched in an identical language—a configuration we term *parallel-test*. This is consistent with the parallel-training settings.

However, in our fine-grained experiments, 429 as presented in Table 5 when the testing environment mimics the cross-training format, dubbed *cross-test*, MathOctopus^C demonstrate a superior performance trajectory compared to MathOctopus \mathcal{P} when model sizes scale from 7B to 33B. This underlines the pivotal importance of en-435 suring a harmonious alignment between training 436

Figure 2: Performances of 7B-models on three languages subset from MGSM.

and testing data formats for optimizing LLMs' multilingual reasoning capability.

3.3.2 Multilingual SFT can generally benefit **Monolingual SFT**

One of the most exciting observations in our experiments is that MathOctopus could significantly improve the performances in Table 6 presents the corresponding English. results of LLaMA and MathOctopus on English GSM8K and SVAMP testsets. First and foremost, both $\texttt{MathOctopus}^\mathcal{P}$ and $\texttt{MathOctopus}^\mathcal{C}$ have substantially enhanced the performance of LLaMA2 across the two datasets. Secondly, MathOctopus^C emerges as the superior performer (e.g., 50.8% vs. 49.3%, 49.3% vs. 46.8% with 7B-level). We surmise that this can be attributed to the cross-training paradigm, where during training, the model predominantly encounters data with English prompts requiring reasoning in other languages. This exposure, intensifies the model's proficiency in English comprehension, providing it with a distinctive edge.

More broadly, does this situation persist in other languages as well? To explore this, we randomly select training sets for three languages from the training dataset: Spanish and Chinese, as well as the low-resource language Thai, and used their respective corpora to train three models, which we named Es-LLaMA, Zh-LLaMA, and Th-LLaMA, respectively. Figure 2 separately illustrates the test results of several models in their respective training languages. We observe that our model still surpasses the results of the monolingual SFT models in their native training languages. This suggests that, at least in the task of math reasoning, multilingual SFT can be considered a superior training strategy to monolingual SFT, effortlessly elevating the model's performance in its native language.

493

494

495

501

In this section, we aim to delve deeper through a series of meticulous experiments designed to address the following inquiries:

- Q1: The impact of xRFT: especially the implications of varying xRFT data quantities on the efficacy of the model?
- Q2: When solely utilizing corpus of specific languages from MGSM8KInstruct for model training, can we still witness an enhancement in other unseen languages? (See Answer in Appendix C)
- Q3: Variations of the training strategy: Step further, instead of strictly restricting the questions to English, we can propose forming pairings from the available corpus of 10 languages in MGSM8KInstruct, thus allowing both the questions and answers to span diverse combinations. How does the model fare under such conditions? (See Answer in Appendix C)

RQ1: Influence of xRFT Data Volume 4.1

In this component, we probe the impact of vary-496 ing data quantities introduced by different xRFTs 497 on model performance. Figures 3 (a) and (b) re-498 spectively illustrate the performances of models 499 across two datasets under xRFT with sampling 500 counts k set to $\{10, 30, 50\}$. From the visuals, it's discernible that for MathOctopus^{\mathcal{P}}, employing larger training corpus generally augments performance in most cases, a trend particularly pronounced in the MGSM dataset. However, these gains remain modest, especially when the backbone model becomes more performant. In con-507 trast, MathOctopus^C demonstrates only marginal 508 improvements attributable to xRFT, and intriguingly, its efficacy on the MSVAMP dataset seems 510 to wane as the k value escalates. 511

This suggests that while xRFT introduces various reasoning paths, its contribution to tasks like multilingual math reasoning remains cir**cumscribed.** A plausible rationale is that during the multilingual SFT phase, distinct linguistic versions of the same solution might already be construed as diverse reasoning paths. Hence, multilingual SFT can essentially be viewed as a variant of the monolingual SFT's RFT. Building upon the foundation of multilingual SFT, supplementary benefits conferred by xRFT appear to be minuscule and might even usher in model overfitting.

5 Conclusion

In this paper, we pioneer to explore training multilingual mathematical LLMs. To address the data scarcity in low-resource languages, We first collect the first multilingual math reasoning instruction dataset, named MGSM8KInstruct, consisting of ten various languages. The models, trained on the MGSM8KInstruct with different training strategies, named MathOctopus, show superior performances compared to other open-source LLMs. We prove that MathOctopus with *parallel-training* could achieve better in-domain test results while MathOctopus with cross-training present better robustness in our collected out-of-domain testset, MSVAMP. We investigate the influences of the multilingual rejection sampling strategy, observing it contributes marginal impact to xMR tasks. Based on our extensive and fine-grained experiments, we also draw several key conclusions, where the most exciting one is that creating aligned bilingual question-answer corpora can be regarded as an important way to improve model performance in its native language, especially in tasks that require mathematical reasoning. Within the picture of our future work, we will explore more methodologies and diverse parallel corpus in training xMR LLMs which may involve the RLHF and DPO.

Math Reasoning with LLMs A pivotal metric for assessing the efficacy of LLMs is their capability in addressing intricate reasoning challenges, exemplified by mathematical reasoning tasks (Scao et al., 2022; Cobbe et al., 2021; Zhou et al., 2022; Weng et al., 2022; Chen et al., 2023b). Rather than yielding direct, definitive answers, prior research has illustrated that by employing a variety of prompting techniques, such as Chain-of-Thought (CoT) prompting (Wei et al., 2022), LLMs can be guided through step-by-step reasoning, resulting in significant improvements in performance across an array of diverse reasoning tasks. Imani et al. (2023) propose the generation of multiple algebraic expressions or Python functions to solve the same mathematical problem, aiming to explore a broader spectrum of potential solutions. Additionally, Li et al. (2023) introduce a step-aware verifier to scrutinize the reasoning steps in COT, thereby enhancing the model's reasoning capabilities. Another effective approach, Self-Consistency (Wang et al., 2022), combines a wider range of solutions and derives a final answer by aggregating them to obtain the most consistent response. Meanwhile, several scholarly works have incorporated the concept of rejection sampling, in conjunction with various other techniques, to curate a more diverse set of sampled reasoning paths for the purpose of fine-tuning data augmentation (Huang et al., 2022; Zelikman et al., 2022; Ni et al., 2023; Zhu et al., 2023; Bai et al., 2022; Yuan et al., 2023b; Dong et al., 2023; Touvron et al., 2023b; Song et al., 2023). Following the line, Yuan et al. (2023a) utilize rejection sampling to augment the data volume for fine-tuning math reasoning LLMs.

Instruction Tuning with LLMs Instruction tun-836 ing serves as a pivotal component within the devel-837 opmental frameworks of language models, with its 838 primary function being to orient LLMs towards ob-839 jectives that are more congruent with human preferences and functional applications. The academic discourse on instruction tuning is notably concen-842 trated on amplifying the versatile instructional capabilities of LLMs. This discourse is particularly exemplified by pioneering studies such as UnifiedQA (Khashabi et al., 2020), Zero-Prompt (Xu et al., 2022), FLAN (Chung et al., 2022), and TO 847 (Sanh et al., 2022). These studies have embarked on an exploration into the generalization capabilities of LLMs. Following these, FLAN-v2 (Longpre 850

et al., 2023) further investigated the impact of scaling instructional datasets on model performance. Recent innovations in this domain are veering towards employing synthetic instruction following data, distilled from models like GPT-3/4 (OpenAI, 2023), to align open-source LLMs. Recently, several works have utilized instruction tuning for training math LLMs. Yuan et al. (2023a) propose RFT in math reasoning, and WizardMath (Luo et al., 2023) implements the "evol-instruct reinforcement learning" methodology (RLEIF), which is directed towards the refinement of prevailing math instruction data. However, almost all of them aim to improve mathematical reasoning in English, leaving multilingual mathematical reasoning less explored. This paper aims to fill this gap by exploring effective methods for training robust LLMs in multilingual mathematical reasoning.

B Experimental Setup

Training and Testing In this work, we use open-source LLaMA-2 7B to 13B and LLaMA-1 33B as backbone models, allowing us to build MathOctopus in multiple scales. Our codes are based on DeepSpeed and Huggingface Library. For all models, we set the learning rate, epochs and max length as 2e-5, 3 and 512. The batch sizes are set to 8, 4, 2 when models scale from 7B to 33B. During testing, we set the maximum output token as 512 with temperature as 0.0 to keep stable performances. We keep the same prompt in Table 7 for testing MathOctopus. Please refer to Section 3.3 for xRFT settings.

C Discussion

C.1 RQ2: Targeted Language Training: Limited Broader Linguistic Reasoning Gains

Our exploration into model training with select languages posits a notable inquiry: Can training with a subset of languages enhance mathematical reasoning across all languages? Engaging two high-resource languages, Spanish and Chinese, and two low-resource languages, Thai and Swahili, for mixed training sessions reveals pivotal insights. Seen in Table 8, while stark performance enhancements are witnessed in trained languages, notably in low-resource ones like Thai (surging from 4% to 36.8%), the model's efficacy varies in languages that are unseen in training: While there are improved outcomes in certain languages like Japanese

	Below is an instruction that describes a task. \n Write a response that appropriately completes the
Input Prompts	request in { language }. Please answer in { language }.\n \n ### Instruction: \n {query}\n\n ###
	Response:

Models	En	Sw	Zh	Bn	De	Es	Fr	JA	Ru	Th	Avg.
LLaMA 2 (En)	43.2	5.2	22.4	3.2	37.2	32.4	34.4	15.2	28.0	4.8	22.6
MathOctopus $^{\mathcal{P}}$ (En-Zh-Es)	44.0	3.6	34.4	3.2	33.6	41.2	36.8	25.2	30.4	4.0	25.6
$\texttt{MathOctopus}^{\mathcal{P}} \text{ (En-Sw-Th)}$	46.0	34.4	27.6	2.4	31.2	35.2	32.4	22.4	27.2	36.8	29.6

Table 7: Training and testing prompts in our experiments.

Table 8: Model Performances on MGSM test set. **MathOctopus**^{\mathcal{P}} (En-Zh-Es) refers to we only train **MathOctopus**^{\mathcal{P}} in three languages: English, Chinese and Spanish. Similarly, **MathOctopus**^{\mathcal{P}} (En-Sw-Th) means the **MathOctopus**^{\mathcal{P}} trained in English, Swahili and Thai.

and French, a corresponding decline is witnessed in others, such as German and Russian. This phenomenon might predominantly stem from the disparities in grammatical structures across different languages (Chen et al., 2023a).

C.2 RQ3: Training Variability: Beyond English-centric Questions

Beyond the two training strategies explored in Section 3.3, we further probe alternative approaches to discern their influence on model performance. Hence, we examine two additional strategies: 1) A **Mix-Training** approach, where cross-training and parallel-training data are amalgamated for training; 2) An expansive **Mix-All** method that not only extends cross-training but also randomly pairs two languages from the MGSM8KInstrucT, thereby permitting questions and answers in the training data to traverse various linguistic combinations, effectively amplifying the original training data volume tenfold. The resulting models obtained by the above strategies are called MathOctopus^M and MathOctopus^M-All, separately.

From the right-side Figure 4, it is evident that despite these two new training strategies respectively doubling and amplifying training volumes tenfold compared to original parallel-training and crosstraining strategies, they do not surpass the results of MathOctopus^{\mathcal{P}}. Furthermore, the outcomes from MathOctopus^{\mathcal{M}}-All slightly underperform MathOctopus^{\mathcal{M}}. Such a phenomenon may arise because, although "mix-all" and "mix-training" expand the original data, the pre-existing data volume already suffices for the model to learn alignment and reasoning capabilities across different languages. An additional, rudimentary data expansion potentially induces overfitting, subsequently

Prompts: You are a professional {lang} translator and spelling corrector. Please translate the given math question and its reasoning path into {lang}.

Q: Weng earns \$12 an hour for babysitting. Yesterday, she just did 50 minutes of babysitting. How much did she earn? P: Babysitting is 12/hour = 12/60 minutes = $\frac{12}{60=0.2} \times 0.2$ per minute. Weng did babysitting for 50 minutes, so she earned $0.2 \times 50 = 0.2 \times 50 = 10 \times 10$.

T-Q: Weng gana 12 dólares la hora por cuidar niños. Ayer cuidó niños durante 50 minutos. ¿Cuánto ganó?

T-P: Cuidar niños cuesta 12/hora = 12/60 minutos = 42/60=0.2 por minute. Weng cuidó niños durante 50 minutos, por lo que ganó $0.2 \times 50 = 0.2 \times 50 = 10 \times 10$.

Q: Julie is reading a 120-page book. Yesterday, she was able to read 12 pages and today, she read twice as many pages as yesterday. If she wants to read half of the remaining pages tomorrow, how many pages should she read?

T-Q: Julie está leyendo un libro de 120 páginas. Ayer pudo leer 12 páginas y hoy leyó el doble que ayer. Si quiere leer la mitad de las páginas restantes mañana, ¿cuántas páginas debería leer?

Please Keep in mind that:

(1) keep the translations consistent for names of people and places within the sentences.

(2) Preserve the mathematical formula within the "« »" brackets when translating.

(3) You must translate the text into {lang}.

(4) You must follow the output format with: "T-Q:... T-P:..."

Table 9: Translation prompts in our experiments.

Prompts: Answer the following math probelm step by step in {lang}.

Below are examples:

Below are examples:

Q: Julia played tag with 18 kids on Monday. She played tag with 10 kids on Tuesday. how many more kids did she play with on Monday than on Tuesday?

A: Let's think step by step. Julia playsed tag with 18 kids on Monday and 10 kids Tuesday, separately. So the amount of kids that she played with on Monday than on Tuesday is 18-10=8. So the answer is 8.

Q: Jack had 9 action figures and 10 books on a shelf in his room. later he added 7 more action figures to the shelf. how many more action figures than books were on his shelf ?

A: Let's think step by step. The amount of action figures that Jack had is 9+7=16. And Jack had 10 books. So the amount of action figures than books on his shelf is 16-10=6. So the answer is 7.
