Graph Neural Networks with Learnable and Optimal Polynomial Bases

Yuhe Guo [1] **Zhewei Wei** [1 2 3 4]

Abstract

Polynomial filters, a kind of Graph Neural Networks, typically use a predetermined polynomial basis and learn the coefficients from the training data. It has been observed that the effectiveness of the model is highly dependent on the property of the polynomial basis. Consequently, two natural and fundamental questions arise: Can we learn a suitable polynomial basis from the training data? Can we determine the optimal polynomial basis for a given graph and node features?

In this paper, we propose two spectral GNN models that provide positive answers to the questions posed above. First, inspired by Favard's Theorem, we propose the FavardGNN model, which learns a polynomial basis from the space of all possible orthonormal bases. Second, we examine the supposedly unsolvable definition of optimal polynomial basis from Wang & Zhang (2022) and propose a simple model, OptBasisGNN, which computes the optimal basis for a given graph structure and graph signal. Extensive experiments are conducted to demonstrate the effectiveness of our proposed models. Our code is available at https://github.com/yuziGuo/FarOptBasis.

1. Introduction

Spectral Graph Neural Networks are a type of Graph Neural Networks that comprise the majority of filter-based GNNs (Shuman et al., 2013; Isufi et al., 2021; 2022). They are designed to create graph signal filters in the spectral domain. To avoid eigendecomposition, spectral GNNs approximate the desired filtering operations by polynomials of laplacian eigenvalues.

Proceedings of the 40^{th} International Conference on Machine Learning, Honolulu, Hawaii, USA. PMLR 202, 2023.

As categorized in He et al. (2022), there are mainly two kinds of spectral GNNs. In some works, the desired polynomial filters are **predefined**. For example, GCN (Kipf & Welling, 2017) fixes the filter to be $I - \hat{L}$, and APPNP (Klicpera et al., 2019) restricts the filtering function within the Personalized Pagerank.

Another line of research approximates **arbitrary** filters with learnable polynomials. These models typically fix a predetermined polynomial basis and learn the coefficients from the training data. ChebNet (Defferrard et al., 2016) uses Chebyshev basis following the tradition of Graph Signal Processing (Hammond et al., 2009). GPR-GNN (Chien et al., 2021) uses Monomial basis, which is straightforward. BernNet (He et al., 2021) uses the non-negative Bernstein basis for regularization and interpretation. JacobiConv (Wang & Zhang, 2022) chooses among the family of Jacobi polynomial bases, with the exact basis determined by two extra hyperparameters. ChebNetII (He et al., 2022) revisits the Chebyshev basis, and incorporates the power of Chebyshev interpolation by reparameterizing learnable coefficients by chebynodes. Please refer to Section 2.1 for more concrete backgrounds about polynomial filtering.

However, there are still two fundamental challenges on the choice of basis.

Challenge 1: It is well known and checked by ablation studies (Wang & Zhang, 2022) that the choice of basis has a significant impact on practical performance. However, the proportion of known polynomial bases is small and may not include the best-fitting basis for a given graph and signal. Therefore, we pose the following question: **Can we learn a polynomial basis from the training data out of all possible orthonormal polynomials?** [1]

Challenge 2: On the other hand, although these bases differ in empirical performances, their expressiveness should be the same: any target polynomial of order K can be represented by any complete polynomial basis with truncated order K (See Figure 1 for an example). Therefore, Wang & Zhang (2022) raised a definition of *optimal basis* from an optimization perspective, which promises an optimal convergence rate. However, this basis is believed to be unsolvable using existing techniques. Consequently, a natural question

[1]For the concrete definition of orthonormal polynomial bases, please check the preliminaries in Section 2.2.

	$k=0$	$k=1$	$k=2$	Representation of $h(\lambda)=\lambda^2+1$
Monomial Basis	$M_0(\lambda)=1$	$M_1(\lambda)=\lambda$	$M_2(\lambda)=\lambda^2$	$h(\lambda)=M_0+M_2(\lambda)$
Chebyshev Basis	$T_0(\lambda)=1$	$T_1(\lambda)=\lambda$	$T_2(\lambda)=\lambda^2-1$	$h(\lambda)=2\cdot T_0(\lambda)+T_2(\lambda)$
Bernstern Basis	$B_{k,2}(\lambda)=\binom{2}{k}\lambda^k(1-\lambda)^{2-k}$ $(k=0,1,2)$			$h(\lambda)=B_{0,2}(\lambda)+B_{1,2}(\lambda)+2\cdot B_{2,2}(\lambda)$

Figure 1. Representation of $h(\lambda) = \lambda^2 + 1$ by different bases.

is: **can we compute this optimal basis for a given graph and signal using innovative techniques?**

In this paper, we provide positive answers to the questions posed above. We summarize our contributions in three folds. Firstly, we propose FavardGNN with **learnable orthonormal basis** to tackle the first challenge. The theoretical basis of FavardGNN is two Theorems in orthogonal polynomials: the Three-term recurrences and its converse, Favard's Theorem. FavardGNN learns from the *whole space* of possible orthonormal basis with $2(K+1)$ extra parameters. Secondly, we propose OptBasisGNN with **solvable optimal basis**. We solve the optimal basis raised by Wang & Zhang (2022) by avoiding the explicit solving of the weight function , which invites the need for eigendecomposition. Note that although we write out the implicitly defined/solved polynomial series in the methodology section, we never need to solve it explicitly. Last but not least, we conduct **extensive experiments** to demonstrate the effectiveness of our proposed models.

2. Background and Preliminaries

2.1. Background of Spectral GNNs

In this section, we provide some necessary backgrounds of spectral graph neural networks, and show how the choice of polynomial bases emerges as a problem. Notations used are summarized in Table 6 in Appendix A.

Graph Fourier Transform. Consider an undirected and connected graph $G = (V, E)$ with N nodes, its symmetric normalized adjacency matrix and laplacian matrix are denoted as $\hat{P}$ and $\hat{L}$, respectively, $\hat{L} = I - \hat{P}$. *Graph Fourier Transform*, as defined in the spatial/spectral domain of graph signal processing, is analogous to the time/frequency domain Fourier Transform (Hammond et al., 2009; Shuman et al., 2013) . One column in the representations of N nodes, $X \in \mathsf{R}^{N\ \ d}$, is considered a *graph signal*, denoted as x. The complete set of N eigenvectors of $\hat{L}$, denoted as U, who show varying structural frequency characteristics (Shuman et al., 2013), are used as *frequency components*. *Graph Fourier Transform* is defined as $\hat{x} := U^T x$, where signal x is projected to the frequency responses of all components. It is then followed by *modulation*, which suppresses or strengthens certain frequency components, denoted as $\hat{x}\ := \mathrm{diag}\{\theta_0, \cdots, \theta_{N\ \ 1}\}\hat{x}$. After modulation, *inverse Fourier Transform*: $x\ := U\hat{x}$ transforms $\hat{x}$ back to the spatial domain. The three operations form the process of *spectral filtering*: $U\,\mathrm{diag}\{\theta_0, \theta_1, \ldots, \theta_{N\ \ 1}\}U^T x$ (1) .

Polynomial Approximated Filtering. In order to avoid time-consuming eigendecomposition, a line of work approximate θ_i by some polynomial function of λ_i, which is the i-th eigenvalue of $\hat{L}$, i.e. $\theta_i \approx h(\lambda_i)$. Equation (1) then becomes a form that is easy for fast *localized* calculation: $U\,\mathrm{diag}\{h(\lambda_0), h(\lambda_1), \ldots, h(\lambda_{N\ \ 1})\}U^T x = h(\hat{L})x$.

As listed in Introduction, various *polynomial bases* have been utilized, denoted as $h(\lambda) = \sum_{k=0}^{K} \alpha_k g_k(\lambda)$. The filtering process on the input signal x is then expressed as $x \to z = \sum_{k=0}^{K} \alpha_k g_k(\hat{P})x$. When consider independent filtering on each of the d channels in X simultaneously, the **multichannel filtering** can be denoted as: $X \to Z = \|_{l2\,[1,h]} \sum_{k=0}^{K} \alpha_{k,l} g_{k,l}(\hat{P})X_{:,l}$ (2).

For further simplicity, we equivalently use $b(\hat{P})$ instead of $h(\hat{L})$ in this paper, where $b(\hat{P}) := h(I - \hat{P})$. Note that $b(\cdot)$ is defined on the spectrum of $\hat{P}$, and the i-th eigenvalue of $\hat{P}$, denoted as μ_i, equals $1 - \lambda_i$.

2.2. Orthogonal and Orthonormal Polynomials

In this section, we give a formal definition of orthogonal and orthonormal polynomials, which plays a central role in the choosing of polynomial bases (Simon, 2014).

Inner Products. The inner product of polynomials is defined as $\langle f, g\rangle := \int_a^b f(x)g(x)w(x)\mathrm{d}x$, where f, g and w are functions of x on interval (a, b), and the *weight function* w should be non-negative to guarantee the positive-definiteness of inner-product space.

The definition of the inner products induces the definitions of *norm* and *orthogonality*. The norm of polynomial f is defined as: $\|f\| = \sqrt{\langle f, f\rangle}$, and f and g are orthogonal to each other when $\langle f, g\rangle = 0$. Notice that the concept of inner product, norm, and orthogonality are all defined with respect to some weight function.

Orthogonal Polynomials. A sequence of polynomials $\{p_n(x)\}_{n=0}^{1}$ where $p_n(x)$ is of exact degree n, is

Algorithm 1: FAVARDFILTERING

Input: Input signals X with d channels; Normalized graph adjacency $\hat{P}$; Truncated polynomial order K
Learnable Parameters : β, γ, α
Output: Filtered Signals Z

$x_{-1} \leftarrow 0$
for $l = 0$ **to** $d-1$ **do**
  $x \leftarrow X_{:,l}$, $x_0 \leftarrow x/\sqrt{\beta_{0,l}}$, $z \leftarrow \alpha_{0,l} x_0$
  for $k = 0$ **to** K **do**
    $x_{k+1} \leftarrow (\hat{P}x_k - \gamma_{k,l}x_k - \sqrt{\beta_{k,l}}x_{k-1})/\sqrt{\beta_{k+1,l}}$
    $z \leftarrow z + \alpha_{k+1,l} x_{k+1}$
  $Z_{:,l} \leftarrow z$
return Z

Algorithm 2: FAVARDGNN (For Classification)

Input: Raw features X_{raw}; Normalized graph adjacency $\hat{P}$; Truncated polynomial order K
Learnable Parameters : W_0, b_0, W_1, b_1, β, γ, α
Output: Label predictions $\hat{Y}$

$X \leftarrow X_{\text{raw}} W_0 + b_0$
$Z \leftarrow$FAVARDFILTERING(X, $\hat{P}$, K, β, γ, α)
$\hat{Y} \leftarrow$Softmax($ZW_1 + b_1$)

called *orthogonal* w.r.t. the positive weight function $w(x)$ if, for $m, n = 0, 1, 2, \cdots$, there exists $\langle p_n, p_m \rangle = \delta_{mn}\|p_n\|^2 (\|p_n\|^2 \neq 0)$, where the inner product $\langle f, g \rangle$ is defined w.r.t. $w(x)$. When $\|p_n\|^2 = 1$ for $n = 0, 1, 2, \cdots$, $\{p_n(x)\}_{n=0}^{\infty}$ is known as **orthonormal** polynomial series.

When a weight function is given, the orthogonal or orthonormal series with respect to the weight function can be solved by *Gram-Schmidt process*.

Remark 2.1. In this paper, the orthogonal/orthonormal polynomial bases we consider are truncated polynomial series, i.e. the polynomials that form a basis are of increasing order.

3. Learnable Basis via Favard's Theorem

Empirically, spectral GNNs with different polynomial bases vary in performance on different datasets, which leads to two observations: (1) the choice of bases matters; (2) whether a basis is preferred might be related to the input, i.e. different signals on their accompanying underlying graphs.

For the first observation, we notice that up to now, polynomial filters *pick* polynomial bases from well-studied polynomials, e.g. Chebyshev polynomials, Bernstein polynomials, *etc*, which narrows down the range of choice. For the second observation, we question the reasonableness of fixing a basis during training. A related effort is made by JacobiConv (Wang et al., 2019), who adapt to a Jacobi polynomial series from the family of Jacobi polynomials via *hyperparameter tuning*. However, the range they choose from is discrete. Therefore, we aim at dynamically **learn** polynomial basis from the input from a **vast range**.

3.1. Recurrence Formula for Orthonormal Bases

Luckily, the Three-term recurrences and Favard's theorem of orthonormal polynomials provide a *continuous* parameter space to learn basis. Generally speaking, three-term recurrences states that every orthonormal polynomial series satisfies a very characteristic form of recurrence relation, and Favard's theorem states the converse.

Theorem 3.1 (Three Term Recurrences for Orthonormal Polynomials)**.** *(Gautschi, 2004, p. 12) For orthonormal polynomials $\{p_k\}_{k=0}^{\infty}$ w.r.t. weight function w, suppose that the leading coefficients of all polynomials are positive, there exists the three-term recurrence relation:*

$$\sqrt{\beta_{k+1}}\, p_{k+1}(x) = (x - \gamma_k)p_k(x) - \sqrt{\beta_k}\, p_{k-1}(x),$$
$$p_{-1}(x) := 0,\ p_0(x) = 1/\sqrt{\beta_0},$$
$$\gamma_k \in \mathsf{R},\ \sqrt{\beta_k} \in \mathsf{R}^+,\ k \geq 0 \qquad (3)$$

with $\beta_0 = \int w(x)\mathrm{d}x$.

Theorem 3.2 (Favard's Theorem; Orthonormal Case)**.** *(Favard, 1935), (Simon, 2005, p. 14) A polynomial series $\{p_k\}_{k=0}^{\infty}$ who satisfies the recurrence relation in Equation (3) is orthonormal w.r.t. a weight function w that $\beta_0 = \int w(x)\mathrm{d}x$.*

By Theorem 3.2, any possible recurrences with the form (3) defines an orthonormal basis. By Theorem 3.1, such a formula covers the whole space of orthonormal polynomials. If we set $\{\sqrt{\beta_k}\}$ and $\{\gamma_k\}$ to be learnable parameters with $\sqrt{\beta_k} > 0 (k \geq 0)$, any orthonormal basis can be obtained.

We put the more general *orthogonal* form of Theorem 3.1 and Theorem 3.2 in Appendix B.1 to B.5. In fact, the property of three-term recurrences for orthogonal polynomials has been used multiple times in the context of current spectral GNNs to reuse $g_k(\hat{P})x$ and $g_{k-1}(\hat{P})x$ for the calculation of $g_{k+1}(\hat{P})x$. Defferrard et al. (2016) owe the fast filtering of ChebNet to employing the three-term recurrences of *Chebyshev polynomials* (the first kind, which is orthogonal w.r.t. $\frac{1}{\sqrt{1-x^2}}$): $T_{k+1}(x) = 2xT_k(x) - T_{k-1}(x)$. Similarly, JacobiConv (Wang & Zhang, 2022) employs the three-term recurrences for *Jacobi polynomials* (orthogonal w.r.t. to $(1-x)^a(1+x)^b$). In this paper, however, we focus on orthonormal bases because they minimize the mutual influence of basis polynomials and the influence of the unequal norms of different basis polynomials.

3.2. FavardGNN

Formulation of FavardGNN. We formally write the architecture of FAVARDGNN (Algorithm 2), with the filtering process illustrated in FAVARDFILTERING (Algorithm 1). Note that the iterative process of Algorithm 1 (lines 3-5) follows exactly from Equation (3) in Favard's Theorem. The key insight is to treat the coefficients β, γ, α in Equation (3) as learnable parameters. Since Theorem 3.1 and Theorem 3.2 state that the orthonormal basis must satisfy the employed iteration and vice versa, it follows that the model can learn a suitable orthonormal polynomial basis from among all possible orthonormal bases.

Following convention, before FAVARDFILTERING, an MLP is used to map the raw features onto the signal channels (often much less than the dimension of raw features). In regression problems, the filtered signals are directly used as predictions; for classification problems, they are combined by another MLP followed by a softmax layer.

Parallel Execution. Note that for convenience of presentation, we write the FAVARDFILTERING Algorithm in a form of nested loops. In fact, the computation on different channels (the inner loop k) is conducted simultaneously. We put more concrete implementation in PyTorch-styled the pseudocode in Appendix C.1.

3.3. Weaknesses of FavardGNN

However, there are still two main weaknesses of FavardGNN. Firstly, the orthogonality lacks interpretability. The weight function w can only be solved analytically in a number of cases (Geronimo & Van Assche, 1991). Even if the weight function is solved, the form of w might be too complicated to understand.

Secondly, FAVARDFILTERING is not good in convergence properties: consider a simplified optimization problem $\min \|Z - Y\|_F^2$ which has been examined in the context of GNN (Xu et al., 2021; Wang & Zhang, 2022), even this problem is non-convex w.r.t the learnable parameters in Z. We will re-examine this problem in the experiment section.

4. Achieving Optimal Basis

Although FavardGNN potentially reaches the whole space of orthonormal polynomial series, on the other hand, we still want to know: **whether there is an optimal and accessible basis** in this vast space.

Recently, Wang & Zhang (2022) raises a criterion for optimal basis. Since different bases are the same in expressiveness, this criterion is induced from an angle of optimization. However, Wang & Zhang (2022) believe that this optimal basis is unreachable. In this section, we follow this definition of optimal basis, and show how we can *exactly* apply this optimal basis to our polynomial filter with $O(K|E|)$ time complexity.

Wang & Zhang (2022) make an essential step towards this question: they derive and define an optimal basis from the angle of optimization. However, they do not exhaust their own finding in their model, since based on a habitual process, they believe that the optimal basis they find is inaccessible. In this section, we show how we can *exactly* apply this optimal basis to our polynomial filter in $O(K|E|)$ time complexity.

4.1. A Review: A Definition for Optimal Basis

We start this section with a quick review of the related part from Wang & Zhang (2022), with a more complete review put in Appendix E.

Definition of Optimal Basis. Wang & Zhang (2022) considers the squared loss $R = \frac{1}{2}\|Z - Y\|_F^2$, where Y is the target signal. Since each signal channel contributes independently to the loss, the authors then consider the loss function channelwisely and ignore the index l, that is, $r = \frac{1}{2}\|z - y\|_F^2$, where $z = \sum_{k=0}^{K} \alpha_k g_k(\hat{P})x$.

The task at hand is to seek a polynomial series $\{g_k\}_{k=0}^K$ which is *optimal* for the convergence of coefficients α. Since r is convex w.r.t. α, the gradient descent's convergence rate reaches optimal when the **Hessian matrix** is identity. The (k_1, k_2) element $(k_1, k_2 \in [0, K])$ of the Hessian matrix is:

$$H_{k_1 k_2} = \frac{\partial^2 r}{\partial \alpha_{k_1} \partial \alpha_{k_2}} = x^T g_{k_2}(\hat{P}) g_{k_1}(\hat{P}) x. \tag{4}$$

Definition 4.1 (Optimal basis for signal x)**.** For a given graph signal x, polynomial basis $\{g_k\}_{k=0}^K$ is optimal in convergence rate when H given in (4) is an **identity matrix**.

Wang & Zhang (2022) further reveal the orthonormality inherent in the optimal basis by rephrasing Equation (4) into $H_{k_1 k_2} = \int_{\mu=\ \ 1}^{1} g_{k_1}(\mu) g_{k_2}(\mu) f(\mu) \mathrm{d}\mu$, where the form of f is given in Proposition 4.2 and and derivation is delayed in Appendix E. Combining Definition 4.1, we soonly get:

Proposition 4.2 (Exact weight function of optimal basis)**.** The optimal polynomial basis in Definition 4.1 is orthonormal w.r.t. weight function f, where $f(\mu) = \frac{\mathtt{M}F(\mu)}{\mathtt{M}\mu}$, with $F(\mu) := \sum_{\mu_i \ \ \mu} (U^T x)_i^2$.

Unachievable Algorithm Towards Optimal Basis. Now we illustrate why Wang & Zhang (2022) believe that though properly defined, this optimal basis is unachievable, and how they took a step back to get their final model. We summarize the process they thought of in Algorithm 3. This process is quite habitual: with the weight function in Propo-

Algorithm 3: (An Unreachable Algorithm for Utilizing Optimal Basis)

Input: Graph signal x; Normalized graph adjacency $\hat{P}$; Truncated polynomial order K
Output: Optimal basis $\{g_k(\cdot)\}_{k=0}^K$

$U, \{\mu_i\}_{i=1}^N \leftarrow$ Eigendecomposition of $\hat{P}$
Calculate $f(\mu)$ as descripted in Proposition 4.2
Use Gram-Schmidt process and weight function $f(\mu)$ to contruct an orthonormal basis $\{g_k\}_{k=0}^K$
Apply $\{g_k\}_{k=0}^K$ in polynomial filtering

sition 4.2 solved, it is natural to use it to determine the first K polynomials by the Gram-Schmidt process and then use the solved polynomials in filtering as other bases, e.g. Chebyshev polynomials. This process is unreachable due to the eigendecomposition step, which is essential for the calculation of f (see Proposition 4.2), but prohibitively expensive for larger graphs.

As a result, Wang & Zhang (2022) came up with a compromise. They allow their model, namely JacoviConv, to choose from the family of orthogonal Jacobi bases, who have "*flexible enough weight functions*", i.e., $(1-\mu)^a(1+\mu)^b$ $(\forall a, b \in (0,1))$. In their implementation, a and b are discretized and chosen via hyperparameter tuning. Obviously, the fraction of possible weight functions JacoviConv can cover is still small, very possibly missing the optimal weight function in Proposition 4.2.

4.2. OptBasisGNN

In this section, we show how the polynomial filter can employ the optimal basis in Definition 4.1 efficiently via an innovative $O(K|E|)$ methodology. Our method does not follow the convention in Algorithm 3 where four progressive steps are included to solve the optimal polynomial bases out and utilize them. Instead, our solution to the optimal bases is implicit, accompanying the process of solving a related vector series. Thus, our method bypasses the untractable eigendecomposition step.

Optimal Vector Basis with Accompanying Polynomials. Still, we consider graph signal filtering on one channel, that is, $x \to z = \sum_{k=0}^K \alpha_k g_k(\hat{P})x$. Instead of taking the matrix polynomial $b(\hat{P}) = \sum_{k=0}^K \alpha_k g_k(\hat{P})$ as a whole, we now regard $\{v_k | v_k := g_k(\hat{P})x\}_{k=0}^K$ as a *vector basis*. Then the filtered signal z is a linear combination of the vector basis, namely $x \to z = \sum_{k=0}^K \alpha_k v_k$ (5). When $\{g_k\}_{k=0}^K$ meets Definition 4.1, for all $k_1, k_2 \in [0, K]$, the vector basis satisfies:

$$v_{k_2}^T v_{k_1} = x^T g_{k_2}(\hat{P}) g_{k_1}(\hat{P}) x = \delta_{k_1 k_2}. \tag{6}$$

Algorithm 4: OPTBASISFILTERING
(**1.** In the comment, we write the implicitly undergoing process of obtaining the accompanying optimal polynomial basis.
2. Steps 1-3 will be further substituted by Algorithm 5 after the derivative of Proposition 4.4.)

Input: Input signals X with d channels; Normalized graph adjacency $\hat{P}$; Order K
Learnable Parameters : α
Output: Filtered signals Z

for $l = 0$ **to** $d-1$ **do**
  $x \leftarrow X_{:,l}$
  $v_0 \leftarrow x/\|x\|$; // $g_0(\mu) = 1/\|x\|$
  $z \leftarrow \alpha_{0,l} v_0$
  for $k = 0$ **to** K **do**
    Step 1: $v_{k+1} \leftarrow \hat{P} v_k$; // $g^*_{k+1}(\mu) := \mu g_k(\mu)$
    Step 2: $v^?_{k+1} \leftarrow v_{k+1} - \sum_{i=0}^k \langle v_{k+1}, v_i \rangle v_i$; // $g^\perp_{k+1}(\mu) := g^*_{k+1}(\mu)$ $\sum_{i=0}^k h v^*_{k+1}, v_i i g_i(\mu)$
    Step 3: $v_{k+1} \leftarrow v^?_{k+1}/\|v^?_{k+1}\|$; // $g_{k+1}(\mu) := g^\perp_{k+1}(\mu)/\|v^\perp_{k+1}\|$
    $z \leftarrow z + \alpha_{k+1,l} v_{k+1}$
  $Z_{:,l} \leftarrow z$
return Z

Given $(\hat{P}, x)$, we term g_k the ***accompanying polynomial*** of a vector v_k if $v_k = g_k(\hat{P})x$. Note that an accompanying polynomial does not always exists for any vector. Following Equation (6), finding the optimal *polynomial* basis for filtering is equivalent to finding a *vector* basis $\{v_k\}_{k=0}^K$ that satisfies two conditions: **Condition 1**: Orthonormality; **Condition 2**: Accompanied by the optimal polynomial basis, that is, $v_k \equiv g_k(\hat{P})x$ establishes for each k, where g_k follows Definition 4.1. We term such $\{v_k\}$ the optimal vector basis.

When focusing solely on Condition 1, one can readily think of the fundamental Gram-Schmidt process, which generates a sequence of orthonormal vectors through a series of iterative steps: each subsequent basis vector is derived by 1) orthogonalization with respect to *all* the previously obtained vectors, and 2) normalization.

Moreover, with a slight generalization, Condition 2 can also be met. As illustrated in our OPTBASISFILTERING algorithm (Algorithm 4), besides Steps 2-3 taken directly from the Gram-Schmidt process to ensure orthonormality, there is an additional Step 1 that guarantees the existence of the *subsequent accompanying polynomial*. To show this, we can write out the accompanying polynomial in each step. Inductively, assuming that the accompanying polynomials for the formerly obtained basis vectors are $g_0, \cdots, g_k$, we can observe immediately from the algorithmic flow that the $(k+1)$-th accompanying polynomial is

Algorithm 5: OBTAINNEXTBASISVECTOR

Input: Normalized graph adjacency $\hat{P}$; **Two** solved basis vectors v_{k-1}, v_k $(k \geq 0)$

Output: v_{k+1}

Step 1: $v_{k+1} \leftarrow \hat{P}v_k$

Step 2: $v^?_{k+1} \leftarrow v_{k+1} - \langle v_{k+1}, v_k\rangle v_k - \langle v_{k+1}, v_{k-1}\rangle v_{k-1}$

Step 3: $v_{k+1} \leftarrow v^?_{k+1}/\|v^?_{k+1}\|$

return v_{k+1}

$$g_{k+1}(\mu) := \big(\mu g_k(\mu) - \sum_{i=0}^{k}\langle v_k, v_i\rangle g_i(\mu)\big)/\|v^?_{k+1}\|, \quad (7)$$

with $g_0(\mu) = 1/\|x\|$ as the initial step. Since for each (k_1, k_2), $x^T g_{k_2}(\hat{P}) g_{k_1}(\hat{P})x = v_{k_1}^T v_{k_2} = \delta_{k_1 k_2}$ establishes, the sequence $g_0, \cdots, g_K$ is exactly the optimal basis in Definition 4.1. Thus, by solving the vectors in the optimal vector basis in order and at the same time apply them in filtering by Equation (5), **we can make implicit yet exact use of the optimal polynomial basis**. Thus, we can make implicit and exact use of the optimal polynomial basis via solving the optimal vector basis and applying them by Equation (5). The cost, due to the recursive conducting over Step 2 until v_K is obtained, is in total $O(K|E| + K^2|V|)$.

Remark 4.3. It is revealed by Equation (7) that we have in fact provided an *alternative solution* to the optimal basis. However, notice that we never need to explicitly compute the polynomial series.

Achieving $O(K|E|+K|V|)$ Time Complexity. We can further reduce the cost to $O(K|E| + K|V|)$ by Proposition 4.4, which shows that in Step 2, instead of subtracting all the former vectors, we just need to subtract v_k and v_{k-1} from v_{k+1}.

Proposition 4.4. In Algorithm 4, v_{k+1} is only dependent with v_k and v_{k-1}.

Proof. Please check Appendix B.6. □

Remark 4.5. The proof is hugely inspired by the core proof part of the Theorem B.1 (Appendix B.1, the three-term recurrences theorem for orthogonal polynomials), which shows that $xp_k(x)$is only relevant to $p_{k+1}(x)$, $p_k(x)$ and $p_{k-1}(x)$. The difference is just a shift of consideration of the inner-product space from polynomials to vectors.

By Proposition 4.4, we substitute Steps 1-3 in Algorithm 4 by Algorithm 5. Note that we define $v_{-1} := \vec{0}, g_{-1}(\mu) := 0$ for consistency and simplicity of presentation. The improved OPTBASISFILTERING algorithm serves as the core part of the complete OptBasisGNN. The processes on all channels are conducted in parallel. Please check the Pytorch-style pseudo-code in Appendix C.2.

4.3. More on the Implicitly Solved Polynomial Basis

This section is a more in-depth discussion about the nature of our method, that is, we implicitly determine the optimal polynomials by *three-term recurrence relations* rather than the *weight function*.

We begin with a lemma. The proof can be found in Appendix B.7.

Lemma 4.6. *In Algorithm 5,* $\|v^?_k\| = \langle v_{k+1}, v_{k-1}\rangle$.

This lemma soonly leads to the following theorem.[2]

Theorem 4.7 (Three-term Recurrences of Accompanying Polynomials (Informal))**.** *The process for deriving the vector basis correspondingly defines the optimal polynomial basis through the following three-term relation:*

$$\|v^?_{k+1}\|\, g_{k+1}(\mu) = (\mu - \langle v_{k+1}, v_k\rangle)g_k(\mu) - \|v^?_k\|\, g_{k-1}(\mu),$$
$$g_{-1}(\mu) := 0,\ g_0(\mu) = 1/\|x\|,$$
$$k = 0, \cdots, K-1.$$

Proof. Combining Proposition 4.4, the accompanyingly derived basis polynomial in Equation (7) comes to

$$\|v^?_{k+1}\|g_{k+1}(\mu) = \mu g_k(\mu) - \sum_{i=k-1}^{k}\langle v_{k+1}, v_i\rangle g_k(\mu).$$

By employing Lemma 4.6 on the right-hand side and staking the steps, the proof is completed. □

This implicit recurring relation revealed in Theorem 4.7 perfectly matches the three-term formula in Equation (3) if we substitute $\|v^?_k\|$ by $\sqrt{\beta_k}$, and $\langle v_{k+1}, v_k\rangle$ by γ_k. This is guaranteed by the orthonormality of the optimal basis (Proposition 4.2) and the three-term recurrence formula that constrains any orthonormal polynomial series (Theorem 3.2). From this perspective, OptBasisGNN is a **particular case** of FavardGNN. FavardGNN is possible to reach the whole space of orthonormal bases, among which OptBasisGNN employs the ones that promise optimal convergence property.

Let us recall the Favard's theorem (Theorem 3.1) and three-term recurrence theorem (Theorem 3.2) from a different perspective: An orthonormal polynomial series can be defined either through a *weight function* or a *recurrence relation* of a specific formula. We adopt the latter definition, bypassing the need for eigendecomposition as a prerequisite for the weight function. Moreover, our adoption of such a way of definition is hidden behind the calculation of vector basis.

[2] Here, x is the input signal.

Algorithm 6: OPTBASISFILTERING

Input: Input signals X with d channels; Normalized graph adjacency $\hat{P}$; Order K
Learnable Parameters : α

  for $k = 0$ **to** K **do**
    $v_{k+1} \leftarrow$OBTAINNEXTBASISVECTOR($\hat{P}$,v_k, v_{k-1})
    $z \leftarrow z + \alpha_{k+1,l} v_{k+1}$
  $Z_{:,l} \leftarrow z$
return Z

4.4. Scale Up OptBasisGNN

By slightly generalizing OptBasisGNN, it becomes feasible to scale it up for significantly larger graphs, such as ogbn-papers100M(Hu et al., 2020). This follows the approach of previous works that achieve scalability in GNNs by decoupling feature propagation from transformation (Chen et al., 2020a; Wu et al., 2019; He et al., 2022). We make several modifications to OptBasisGNN. First, we remove the MLP layer before OPTBASISFILTERING, resulting in the optimal basis vectors for all channels being computed in just one pass. Second, we preprocess the entire set of basis vectors ($V \in \mathsf{R}^{d\ (K+1)\ N}$) on CPU. Third, we adopt batch training, where for each batch of nodes $\mathcal{B}$, the corresponding segment of basis vectors $V[:,:,\mathcal{B}]$ is transferred to the GPU.

5. Experiments

In this section, we conduct a series of comprehensive experiments to demonstrate the effectiveness of the proposed methods. Experiments consist of node classification tasks on small and large graphs, the learning of multi-channel filters, and a comparison of FavardGNN and OptBasisGNN.

5.1. Node Classification

Experimental Setup. We include medium-sized graph datasets conventionally used in preceding graph filtering works, including three heterophilic datasets (Chameleon, Squirrel, Actor) provided by Pei et al. (2020) and two citation datasets (PubMed, Citeseer) provided by Yang et al. (2016) and Sen et al. (2008) . For all these graphs, we take a $60\%/20\%/20\%$ train/validation/test split proportion following former works, e.g. Chien et al. (2021). We report our results of twenty runs over random splits with random initialization seeds. For baselines, we choose sota spectral GNNs. For other experimental settings, please refer to Appendix D.1. Besides, for evaluation of OptBasisGNN, please also check the results in the scalability experimental section (Section 5.2).

Results. As shown in Table 1, FavardGNN and OptBasisGNN outperform most strong baselines. Especially, in Chameleon, Squirrel and Actor, we see a big lift. The vast selection range and learnable nature of FavardGNN and the optimality of convergence provided by OptBasisGNN both enhance the performance of polynomial filters, and their performances hold flat.

5.2. Node Classification on Large Datasets

Experimental Setup. We perform node classification tasks on two large citation networks: ogbn-arxiv and ogbn-papers100M (Hu et al., 2020), and five large non-homophilic networks from the LINKX datasets (Lim et al., 2021) . Except for Penn94, Genius and Twitch-Gamers, all other mentioned datasets use the scaled version of OptBasisGNN.

For ogbn datasets, we run repeating experiments on the given split with ten random model seeds, and choose baselines following the scalability experiments in ChebNetII (He et al., 2022). For LINKX datasets, we use the five given splits to align with other reported experiment results for Penn94, Genius, Twitch-Gamer and Pokec. For Wiki dataset, since the splits are not provided, we use five random splits. For baselines, we choose spectral GNNs as well as top-performing spatial models reported by Lim et al. (2021), including LINK, LINKX, GCNII (Chen et al., 2020b) and MixHop (Abu-El-Haija et al., 2019). For more detailed experimental settings, please refer to Appendix D.1.

Results. As shown in Table 2 and Table 3, On Penn94, Genius and Twitch-gamer, our two models achieve comparable results to those of the state-of-the-art spectral methods. On ogbn datasets as well as Pokec and Wiki with tens or hundreds of edges, we use the scaled version of OptBasisGNN with batch training. We do not conduct FavardGNN on these datasets, since the basis vectors of FavardGNN are cannot be precomputed. Notably, on Wiki dataset, the largest non-homophilous dataset, our method surpasses the second top method by nearly one percent, this demonstrates the effectiveness of our scaled-up version of OptBasisGNN.

5.3. Learning Multi-Channel Filters from Signals

Experimental Setup. We extend the experiment of learning filters conducted by He et al. (2021) and Balcilar et al. (2021). The differences are twofold: First, we consider the case of *multi-channel* input signals and learn filters *channelwisely*. Second, the *only* learnable parameters are the coefficients α. Note that the optimization target of this experiment is identical to how the optimal basis was derived by Wang & Zhang (2022) (See Section 4.1).

We put the practical background of our multichannel ex-

Table 1. **Experimental results.** *Accuracies* 95% *confidence intervals* are displayed for each model on each dataset. The best-performing two results are highlighted. The results of GPRGNN are taken from He et al. (2021). The results of BernNet, ChebNetII and JacobiConv are taken from original papers. The results of FavardGNN and OptBasisGNN are the average of repeating experiments over 20 cross-validation splits.

periment in YCbCr color space. Each 100×100 image is considered as a grid graph with input node signals on three channels: Y, Cb and Cr. Each signal might be filtered by complex filtering operations defined in (He et al., 2021). As shown in Table 4, using different filters on each channel results in different combination effects. We create a synthetic dataset with 60 samples from 15 original images. More

Table 4. Illustration of our multichannel filter learning experiment.

Original Image	Y: Band Reject Cb: :Low pass Cr: High Pass	Y: Low Pass Cb: Band Reject Cr: Band Reject
		

about the synthetic dataset are in Appendix D.2.

Following He et al. (2021), we use input signals X and the true filtered signals Y to supervise the learning process of α. The optimization goal is to minimize $\frac{1}{2}\|Z-Y\|_2^2$, where Z is the output multi-channel signal defined in Equation (2). During training, we use an Adam optimizer with a learning rate of 0.1 and a weight decay of $5\mathrm{e}{-4}$. We allow a maximum of 500 epochs, and stop iteration when the difference of losses between two epochs is less than $1\mathrm{e}{-4}$.

For baselines, we choose the Monomial basis, Bernstein basis, Chebyshev basis (with Chebyshev interpolation) corresponding to GPR-GNN, BernNet and ChebNetII, respectively. We also include arbitrary orthonormal basis learned by Favard for comparison. Note that, we learn *different*

filters on each channel for all baseline basis for fairness.

Results. We exhibit the mean MSE losses with standard errors of the 60 samples achieved by different bases in Table 5. Optbasis, which promises the best convergence property, demonstrates an overwhelming advantage. A special note is needed that, the Monomial basis has *not finished converging* at the maximum allowed 500th epoch. In Section 5.4, we extend the maximum allowed epochs to 10,000, and use the slowly-converging Monomial basis curve as a counterpoint to the non-converging Favard curve.

Particularly, in Figure 2, we visualize the converging process on **one sample**. Obviously, OptBasis show **best convergence property** in terms of both the fastest speed and smallest MSE error. Check Appendix D.2 for more samples.

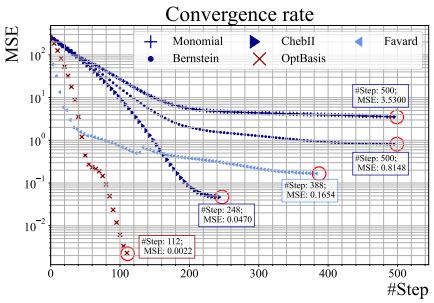

Figure 2. Convergence rate of minimizing $\frac{1}{2}kZ \quad Yk_2^2$ on one sample. *Sample message*: The true filters for this sample are low-pass(Y) / band-reject(Cb) / band-reject(Cr). *Legends*: ChebII means using Chebyshev polynomials combined with interpolation on chebynodes as in ChebNetII (He et al., 2022). Favard means the bases are learned as FavardGNN. In 500 epochs, the experimental groups of the Monomial basis and Bernstein basis did not converge. OptBasis achieves the smallest MSE error in the shortest time.

5.4. Non-Convergence of FavardGNN

Notably, in Figure 2, an obvious *bump* appeared near the 130th epoch. We now re-examine the non-convergence problem of FavardGNN (Section 3.3). We rerun the multi-channel filter learning task by canceling early stopping and stretching the epoch number to 10,000. As shown in Figure 3 (left), the curve of Favard bump several times. In contrast with Favard is the Monomial basis, though showing an inferior performance in Table 5, it converges slowly but stably. We observe a similar phenomenon with a node classification setup in Figure 3 (right) (See Appendix D.3 for details). Still, very large bumps appear. Such a phenomenon might seem contradictory to the outstanding performance of FavardGNN in node classification tasks. We owe the good performances in Table 1 and 2 to the early stop mechanism.

Table 5. Experimental results of the multichannel filtering learning task. *MSE loss* *standard errors* of the 60 samples achieved by different bases are exhibited.

BASIS	OptBasis	ChebII	Bernstein	Favard	Monomial
MSE	**0.0058**	0.1501	0.4231	0.3175	3.9076
± STDV	± **0.0157**	± 0.2433	± 0.4918	± 0.2840	± 2.9263

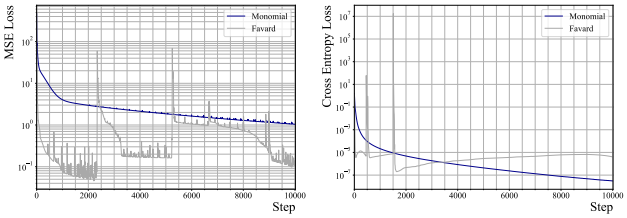

Figure 3. Drop of loss in 10,000 epochs. *Left*: MSE loss of regression task on one sample. *Right*: Cross entropy loss of classification problem on the Chameleon dataset. Models based on Monomial basis converge slowly, but stably. while FavardGNNs don't converge. For the convergence curve for OptBasis, please check Figure 2. It converges much faster than Monomial Basis.

6. Conclusion

In this paper, we tackle the fundamental challenges of basis learning and computation in polynomial filters. We propose two models: FavardGNN and OptBasisGNN. FavardGNN learns arbitrary basis from the whole space of orthonormal polynomials, which is rooted in classical theorems in orthonormal polynomials. OptBasisGNN leverages the optimal basis defined by Wang & Zhang (2022) efficiently, which was thought unsolvable. Extensive experiments are conducted to demonstrate the effectiveness of our proposed models. An interesting future direction is to derive a convex and easier-to-optimize algorithm for FavardGNN.

A. Notations

Table 6. Summation of notations in this paper.

Notation	Description
$G = (V, E)$	Undirected, connected graph
N	Number of nodes in G
$\hat{P}$	Symmetric-normalized adjacency matrix of G.
$\hat{L}$	Normalized Laplacian matrix of G. $\hat{L} = I - \hat{P}$.
λ_i	The i-th eigenvalue of $\hat{L}$.
μ_i	The i-th eigenvalue of $\hat{P}$. $\mu_i = 1 - \lambda_i$.
U	Eigen vectors of $\hat{L}$ and $\hat{P}$.
x	Input signal on 1 channel.
$X \in \mathsf{R}^{N \quad d}$	Input features / Input signals on d channels.
$Z \in \mathsf{R}^{N \quad d}$	Filtered signals.
$h(\cdot), b(\cdot)$	Filtering function defined on $\hat{L}$ and $\hat{P}$, respectively. $h(\lambda) \equiv b(1 - \lambda)$.
$h_i(\cdot), b_i(\cdot)$	Filtering function on the ith signal channel. $X_{i,:} = h_i(\hat{L})Z_{i,:}$.
$h(\hat{L})x, b(\hat{P})x$	Filtering operation on signal x. $h(\hat{L}) \equiv b(\hat{P})$.
$\{g_k(\cdot)\}_{k=0}^{K}$	A polynomial basis of truncated order K.
$\{\alpha_k\}_{k=0}^{K}$	Coefficients above a basis. i.e. $h(\lambda) \approx \sum_{k=0}^{K} \alpha_k g_k(\lambda)$.

B. Proofs

Most subsections here are for the convenience of interested readers. We provided our proofs about the theorems (except for the original form of Favard's Theorem) and their relations used across our paper, although the theorems can be found in early chapters of monographs about orthogonal polynomials (Gautschi, 2004; Simon, 2014). We assume a relatively minimal prior background in orthogonal polynomials.

B.1. Three-term Recurrences for Orthogonal Polynomials (With Proof)

Theorem B.1 (Three-term Recurrences for Orthogonal Polynomials). *(Simon, 2005, p. 12) For any orthogonal polynomial series $\{p_k(x)\}_{k=0}^{1}$, suppose that the leading coefficients of all polynomial are positive, the series satisfies the recurrence relation:*

$$p_{k+1}(x) = (A_k x + B_k)p_k(x) + C_k p_{k \quad 1}(x),$$
$$p_{\quad 1}(x) := 0, A_k, C_k \in \mathsf{R}^{+}, \ B_k \in \mathsf{R}, \ k \geq 0.$$

Proof. The core part of this proof is that xp_k is orthogonal to p_i for $i \leq k - 2$, i.e.

$$\langle xp_k, p_i \rangle = 0, \quad i \leq k - 2.$$

Since $xp_k(x)$ is of order $k + 1$, we can rewrite $xp_k(x)$ into the combination of first $k + 1$ polynomials of the basis:

$$xp_k(x) = \alpha_{k,k+1}p_{k+1}(x) + \alpha_{k,k}p_k(x) + a_{k,k \quad 1}p_{k \quad 1}(x) + \cdots + \alpha_{k,0}p_0(x) \tag{8}$$

or in short,

$$xp_k(x) = \sum_{j=k+1}^{0} \alpha_{k,j}p_j(x).$$

Project each term onto $p_i(x)$,

$$\langle xp_k(x), p_i(x) \rangle = \sum_{j=k+1}^{0} \alpha_{k,j} \langle p_j(x), p_i(x) \rangle.$$

Using the orthogonality among $\{p_k(x)\}_{k=0}^{1}$, we have

$$\langle xp_k(x), p_i(x)\rangle = \langle \alpha_{k,i}p_i(x), p_i(x)\rangle \Rightarrow \alpha_{k,i} = \frac{\langle xp_k(x), p_i(x)\rangle}{\langle p_i(x), p_i(x)\rangle}. \tag{9}$$

Next, we show $\langle xp_k(x), p_i(x)\rangle = 0$ when $i \leq k-2$. Since $\langle xp_k(x), p_i(x)\rangle \equiv \langle p_k(x), xp_i(x)\rangle$, it is equivalent to show $\langle p_k(x), xp_i(x)\rangle = 0$.

When $i \leq k-2$, applying $xp_i(x) = \sum_{j=0}^{i+1} \alpha_{i,j}p_j(x)$ and the orthogonality between $p_j(x)$ and $p_k(x)$ when $j \neq k$, we get

$$\langle p_k, xp_i(x)\rangle = \sum_{j=0}^{i+1} \alpha_{i,j}\langle p_k, p_j(x)\rangle^{\ j \ \overset{k}{=}\ 1} 0 \Rightarrow \langle xp_k, p_i(x)\rangle = 0.$$

Therefore, $xp_k(x)$is only relevant to $p_{k+1}(x)$, $p_k(x)$ and $p_{k\ \ 1}(x)$. By shifting items, we soonly get that: $p_{k+1}(x)$is only relevant to $xp_k(x)$, $p_k(x)$ and $p_{k\ \ 1}(x)$.

At last, we show that, by regularizing the leading coefficients A_k to be positive, $C_k > 0$. Firstly, since the leading coefficients are positive, $\{\alpha_k\}_{k=0}^{1}$ defined in Equation (8) are positive. Then, notice from Equation (9), we get

$$-\frac{C_k}{A_k} = \alpha_{k,k\ \ 1} = \frac{\langle xp_k(x), p_{k\ \ 1}(x)\rangle}{\langle p_{k\ \ 1}(x), p_{k\ \ 1}(x)\rangle} = \frac{\langle p_k(x), xp_{k\ \ 1}(x)\rangle}{\langle p_{k\ \ 1}(x), p_{k\ \ 1}(x)\rangle} = \frac{\alpha_{k\ \ 1,k}}{\langle p_{k\ \ 1}(x), p_{k\ \ 1}(x)\rangle}.$$

We have finished our proof. □

B.2. Favard's Theorem (Monomial Case)

Theorem B.2 (Favard's Theorem). *(Favard, 1935) If a sequence of monic polynomials $\{P_n\}_{n=0}^{1}$ satisfies a three-term recurrence relation*

$$P_{n+1}(x) = (x - \gamma_n)\,P_n(x) - \beta_n P_{n\ \ 1}(x),$$

with $\gamma_n, \beta_n \in \mathsf{R}, \beta_n > 0$, then $\{P_n\}_{n=0}^{1}$ is orthogonal with respect to some positive weight function.

B.3. Favard's Theorem (General Case) (With Proof)

Corollary B.3 (Favard's Theorem; general case). *If a sequence of polynomials $\{P_n\}_{n}^{1}$ satisfies a three-term recurrence relation*

$$P_{n+1}(x) = (\varsigma_n x - \gamma_n)\,P_n(x) - \beta_n P_{n\ \ 1}(x),$$

with $\gamma_n, \beta_n, \varsigma_n \in \mathsf{R}, \varsigma_n \neq 0, \beta_n/\varsigma_n > 0$, then there exists a positive weight function w such that $\{P_n\}_{n=0}^{1}$ is orthogonal with respect to the inner product $\langle p, q\rangle = \int_{\mathbb{R}} p(x)q(x)w(x)\mathrm{d}x$.

Proof. Set $\gamma_n = \frac{\alpha_n}{\varsigma_n}, \beta_n = \frac{\beta_n}{\varsigma_n}$. Then we can construct a sequence of polynomials $\{P_n\}_{n}^{1}$.

Case 1: For $n = 0$ and $n = 1$, set $P_n := P_n(x)/\hat{P}_n(x)$.

Case 2: For $n \geq 2$, define $P_n(x)$ by the three-term recurrences:

$$P_{n+1}(x) := (x - \gamma_n)\,P_n(x) - \beta_n P_{n\ \ 1}(x).$$

According to Theorem B.2, $\{P_n\}_n$ is an orthogonal basis. Since P_n is scaled P_n by some constant, so $\{P_n\}_n$ is also orthogonal. □

B.4. Proof of Theorem 3.1

We restate the Theorem of three-term recurrences for orthonormal polynomials (Theorem 3.1) as below, and give a proof.

(Three Term Recurrences for Orthonormal Polynomials) For orthonormal polynomials $\{p_k\}_{k=0}^{1}$ w.r.t. weight function w, suppose that the leading coefficients of all polynomial are positive, there exists the three-term recurrence relation:

$$\sqrt{\beta_{k+1}}p_{k+1}(x) = (x-\gamma_k)p_k(x) - \sqrt{\beta_k}p_{k\ \ 1}(x),$$
$$p_{\ \ 1}(x) := 0,\ p_0(x) = 1/\sqrt{\beta_0},\ \gamma_k \in \mathsf{R},\ \sqrt{\beta_k} \in \mathsf{R}^+,\ k \geq 0$$

with $\beta_0 = \int w(x)\mathrm{d}x$.

Proof. **Case 1**: $k = 0$. $p_k(x)$ is a constant. Suppose it to be t, then

$$\langle p_0(x), p_0(x)\rangle = t^2 \int_a^b \mathrm{d}\alpha \Rightarrow t = 1/\sqrt{\beta_0}.$$

Case 2: $k \geq 1$. By Theorem B.1, since $\{p_k\}_{k=0}^{K}$ is orthogonal, there exist three term recurrences as such:

$$p_{k+1}(x) = (A_k x + B_k)p_k(x) + C_k p_{k\ \ 1}(x), \quad k = 1, 2, 3, \ldots.$$

By setting $c_k = \dfrac{1}{A_k}$, $a_k = -\dfrac{B_k}{A_k}$, $b_k = -\dfrac{C_k}{A_k}$, it can be rewritten into

$$c_k p_{k+1}(x) = (x - a_k)p_k(x) - b_k p_{k\ \ 1}(x), \quad k = 1, 2, 3, \ldots. \tag{10}$$

Apply dot products with $p_{k\ \ 1}(x)$ to Equation (10), we get

$$\begin{aligned} \langle xp_k(x), p_{k\ \ 1}(x)\rangle &= \langle b_k p_{k\ \ 1}(x), p_{k\ \ 1}(x)\rangle \\ &\Rightarrow\ b_k = \langle xp_k(x), p_{k\ \ 1}(x)\rangle \\ &\quad\ (k = 1, 2, 3, \ldots). \end{aligned} \tag{11}$$

Similarly, apply dot products with $p_{k+1}(x)$, we get:

$$\begin{aligned} \langle c_k p_{k+1}(x), p_{k+1}(x)\rangle &= \langle xp_k(x), p_{k+1}(x)\rangle \\ &\Rightarrow\ c_k = \langle xp_k(x), p_{k+1}(x)\rangle \\ &\Rightarrow\ c_k = \langle xp_{k+1}(x), p_k(x)\rangle \\ &\quad\ (k = 1, 2, 3, \ldots). \end{aligned} \tag{12}$$

Notice that in Equation (12)

$$\langle xp_k(x), p_{k+1}(x)\rangle = \langle p_k(x), xp_{k+1}(x)\rangle \overset{(11)}{=} b_{k+1}.$$

We get:

$$c_k = b_{k+1}.$$

So we can write Equation (10) into the form below:

$$b_{k+1}p_{k+1}(x) = (x - a_k)p_k(x) - b_k p_{k\ \ 1}(x), \quad k = 1, 2, 3, \ldots.$$

At last, we show $b_k > 0$.

Firstly, recall that $b_k = \langle xp_k(x), p_{k\ \ 1}(x)\rangle = \langle p_k(x), xp_{k\ \ 1}(x)\rangle$. Since $xp_{k\ \ 1}(x)$, which is of order k, can be written into the combination of $\{p_j\}_{j=0}^{k}$ which the leading coefficients to be non-zero, i.e.

$$xp_{k\ \ 1}(x) = a_{k,k}p_k(x) + a_{k,k\ \ 1}p_{k\ \ 1}(x) + \cdots + a_{k,0}p_0(x) \quad (a_{k,k} \neq 0)$$

Secondly, since $\langle g(x), g(x)\rangle \equiv \langle -g(x), -g(x)\rangle$, we can restrict all the leading coefficients to be positive.

$$b_n = \langle p_k(x), xp_{k\ \ 1}(x)\rangle = a_{k,k} > 0.$$

Thus we have proved $b_k > 0$ holds.

Furthermore, we can rewrite b_k into $\sqrt{\beta_k}$. The proof is finished. □

B.5. Proof of Theorem 3.2

We restate Favard's Theorem for orthonormal polynomials (Theorem 3.2) as below, and give a proof based on the general case B.3.

(Favard Theorem; Orthonormal case) A polynomial series $\{p_k\}_{k=0}^{1}$ who satisfies the recurrence relation

$$\sqrt{\beta_{k+1}}p_{k+1}(x) = (x-\gamma_k)p_k(x) - \sqrt{\beta_k}p_{k\ \ 1}(x),$$
$$p_{\ \ 1}(x) := 0,\ p_0(x) = 1/\sqrt{\beta_0}, \gamma_k \in \mathsf{R},\ \sqrt{\beta_k} \in \mathsf{R}^+,\ k \geq 0$$

is orthonormal w.r.t. a weight function w that $\beta_0 = \int w(x)\mathrm{d}x$.

Proof. First of all, according to Theorem 3.2, the series $\{p_k\}_{k=0}^{1}$ is orthogonal.

Apply dot products with $p_{k\ \ 1}(x)$, we get

$$\begin{aligned} \langle xp_k(x), p_{k\ \ 1}(x)\rangle &= \left\langle \sqrt{\beta_k}p_{k\ \ 1}(x), p_{k\ \ 1}(x)\right\rangle \\ \Rightarrow \langle xp_k(x), p_{k\ \ 1}(x)\rangle &= \sqrt{\beta_k}\langle p_{k\ \ 1}(x), p_{k\ \ 1}(x)\rangle \\ & \quad (k=0,1,\ldots). \end{aligned}$$

Similarily, apply dot products with $p_{k+1}(x)$, we get:

$$\begin{aligned} \left\langle \sqrt{\beta_{k+1}}p_{k+1}(x), p_{k+1}(x)\right\rangle &= \langle xp_k(x), p_{k+1}(x)\rangle \\ \Rightarrow \sqrt{\beta_{k+1}}\langle p_{k+1}(x), p_{k+1}(x)\rangle &= \langle xp_k(x), p_{k+1}(x)\rangle \\ & \quad (k=0,1,\ldots), \end{aligned}$$

which can be rewritten as:

$$\begin{aligned} \sqrt{\beta_k}\langle p_k(x), p_k(x)\rangle &= \langle xp_{k\ \ 1}(x), p_k(x)\rangle \\ & \quad (k=1,2,\ldots), \end{aligned}$$

Notice that

$$\langle xp_{k\ \ 1}(x), p_k(x)\rangle = \langle xp_k(x), p_{k\ \ 1}(x)\rangle.$$

We get:

$$\begin{aligned} \sqrt{\beta_k}\langle p_k(x), p_k(x)\rangle &= \langle xp_{k\ \ 1}(x), p_k(x)\rangle \\ &= \sqrt{\beta_k}\langle p_{k\ \ 1}(x), p_{k\ \ 1}(x)\rangle \\ \Rightarrow \langle p_k(x), p_k(x)\rangle &= \langle p_{k\ \ 1}(x), p_{k\ \ 1}(x)\rangle \\ & \quad (k=1,2,\ldots), \end{aligned}$$

which indicates that the polynomials $\{p_k\}_{k=0}^{K}$ are same in their norm.

Since $p_0(x) \equiv 1/\sqrt{\beta_0}$ and $\beta_0 = \int w(x)\mathrm{d}x$, $\langle p_0(x), p_0(x)\rangle = \frac{1}{\beta_0}\int w(x)\mathrm{d}x$ =1. Thus the norm of every polynomial in $\{p_k\}_{k=0}^{1}$ equals 1.

Combining that $\{p_k\}_{k=0}^{1}$ is orthogonal and $\langle p_k(x), p_k(x)\rangle = 1$ for all k, we arrive that $\{p_k\}_{k=0}^{1}$ is an orthonormal basis. □

B.6. Proof of Proposition 4.4

Proof. First, from the construction of each v_{i+1} (Algorithm 4, $k = i$), we know that v_{i+1} is composed of $\{v_j\}_j^{j=i}$ and $\hat{P}v_i$. Therefore, $\hat{P}v_i$ can be expressed as a weighted sum of $\{v_j\}_{j=0}^{i+1}$, denoted as $\hat{P}v_i = t_{i+1}v_{i+1} + t_i v_i + \cdots + t_0 v_0$ (13). Second, notice that $\langle \hat{P}v_k, v_i\rangle = v_k^T \hat{P} v_i = \langle v_k, \hat{P}v_i\rangle$ (14). Thus, for Step 2 in Algorithm 4, for each $i \in [0, 1, \cdots, k]$ we can rephrase $\langle v_{k+1}, v_i\rangle$ by:

$$\begin{aligned}\langle v_{k+1}, v_i\rangle &\overset{\text{def}}{=} \langle \hat{P}v_k, v_i\rangle \overset{(14)}{=} \langle v_k, \hat{P}v_i\rangle \\ &\overset{(13)}{=} \left\langle v_k, \sum_{j=0}^{i+1} t_j v_j \right\rangle \\ &= \sum_{j=0}^{i+1} t_j \langle v_k, v_j\rangle,\end{aligned}$$

which equals 0 when $i < k - 1$. □

B.7. Proof of Lemma 4.6

Proof. First, notice that

$$\langle v_{k+1}, v_{k\ \ 1}\rangle = \langle \hat{P}v_k, v_{k\ \ 1}\rangle = \langle v_k, \hat{P}v_{k\ \ 1}\rangle.$$

On the other hand,

$$\|v^?_{k+1}\| = \langle v_{k+1}, v^?_{k+1}\rangle = \langle v_{k+1}, v_{k+1}\rangle = \langle v_{k+1}, \hat{P}v_k\rangle.$$

So, we get

$$\|v^?_k\| = \langle v_k, \hat{P}v_{k\ \ 1}\rangle = \langle \hat{P}v_k, v_{k\ \ 1}\rangle = \langle v_{k+1}, v_{k\ \ 1}\rangle.$$

□

Thus, we have finished our proof.

C. Pseudo-codes

C.1. Pseudo-code for FavardGNN.

Pred = Softmax(Y)
return Pred
```

D. Experimental Settings.

D.1. Node Classification Tasks on Large and Small Datasets.

Model setup. The structure of FavardGNN and OptBasisGNN follow Algorithm 2. The hidden size of the first MLP layers h is set to be 64, which is also the number of filter channels. For the scaled-up OptBasisGNN, we drop the first MLP layer to fix the basis vectors needed for precomputing, and following the scaled-up version of ChebNetII (He et al., 2022), we add a three-layer MLP with weight matrices of shape $F \times h$, $h \times h$ and $h \times c$ after the filtering process.

For both models, the initialization of α is set as follows: for each channel l, the coefficients of the $g_{0,l}$ are set to be 1, while the other coefficients are set as zeros, which corresponds to initializing the polynomial filter on each channel to be $h(\lambda) = 1 - \lambda$. For the initialization of three-term parameters that determine the initial polynomial bases on each channel, we simply set $\{\sqrt{\beta}\}$ to be ones, and $\{\gamma\}$ to be zeros.

Hyperparameter tunning. For the optimization process on the training sets, we tune all the parameters with Adam (Kingma & Ba, 2015) optimizer. We use early stopping with a patience of 300 epochs.

We choose hyperparameters on the validation sets. To accelerate hyperparameter choosing, we use Optuna(Akiba et al.,

2019) to select hyperparameters from the range below with a maximum of 100 complete trials[3]:

1. Truncated Order polynomial series: $K \in \{2, 4, 8, 12, 16, 20\}$;
2. Learning rates: $\{0.0005, 0.001, 0.005, 0.1, 0.2, 0.3, 0.4, 0.5\}$;
3. Weight decays: $\{1\mathrm{e}{-8}, \cdots, 1\mathrm{e}{-3}\}$;
4. Dropout rates: $\{0., 0.1, \cdots, 0.9\}$;

There are two extra hyperparameters for scaled-up OptBasisGNN:

1. Batch size: $\{10,000, 50,000\}$;
2. Hidden size (for the post-filtering MLP): $\{512, 1024, 2048\}$.

D.2. Multi-Channel Filter Learning Task.

YCbCr Channels. We put the practical background of our multichannel experiment in the YCbCr color space, a useful color space in computer vision and multi-media (Shaik et al., 2015).

Our Synthetic Dataset. When creating our datasets with 60 samples, we use 4 filter combinations on 15 images in He et al. (2021)'s single filter learning datasets. The 4 combinations on the three channels are:

1. Band-reject(Y) / low-pass(Cb) / high-pass(Cr);
2. High-pass(Y) / High-pass(Cb) / low-pass(Cr);
3. High-pass(Y) / low-pass(Cb) / High-pass(Cr);
4. Low-pass(Y) / band-reject(Cb) / band-reject(Cr).

The concrete definitions of the signals, i.e. band-reject are aligned with those given in He et al. (2022).

Visualization on more samples. We visualize more samples as Figure 2 in Figure 4. In all the samples, the tendencies of different curves are alike.

D.3. Examining of FavardGNN's bump.

Figure 3 (right), we observe bump with a node classification setup. To show this clearer, we let FavardGNN and GPR-GNN (which uses the Monomial basis for classification) to fit *the whole set* of nodes, and move dropout and Relu layers. As in the regression re-examine task, we cancel the earlystop mechanism, stretch the epoch number to 10,000, and record cross entropy loss on each epoch.

E. Summary of Wang's work

This section is a restate for a part of Wang & Zhang (2022). For the convenience of the reader's reference, we write this section here. More interested readers are encouraged to refer to the original paper.

Wang & Zhang (2022) raise a criterion for best basis, but states that it **cannot be reached**.

E.1. The Criterion for Optimal Basis

Following Xu et al. (2021), Wang & Zhang (2022) considers the squared loss $R = \frac{1}{2}\|Z - Y\|_F^2$, where Y is the target , and $Z = \underset{l2[1,h]}{\|} \sum_{k=0}^{K} \alpha_{k,l} g_{k,l}(\hat{P}) X_{:,l}$. [4]

Since each signal channel is independent and contributes independently to the loss, i.e. $R = \sum_l \frac{1}{2}\|Z_{:,l} - Y_{:,l}\|_F^2$, we can then consider the loss function channelwisely and ignore l. Loss on one signal channel x is:

$$r = \frac{1}{2}\|z - y\|_F^2,$$

[3] We use Optuna's Pruner to drop some hyperparameter choice in an early stay of training. This is called an incomplete/pruned trial.

[4] Here, X is not necessarily the raw feature (X_{raw}) but often some thing like $X_{raw}W$. W is irrelevant to the choice of polynomial basis, and merges W into X.

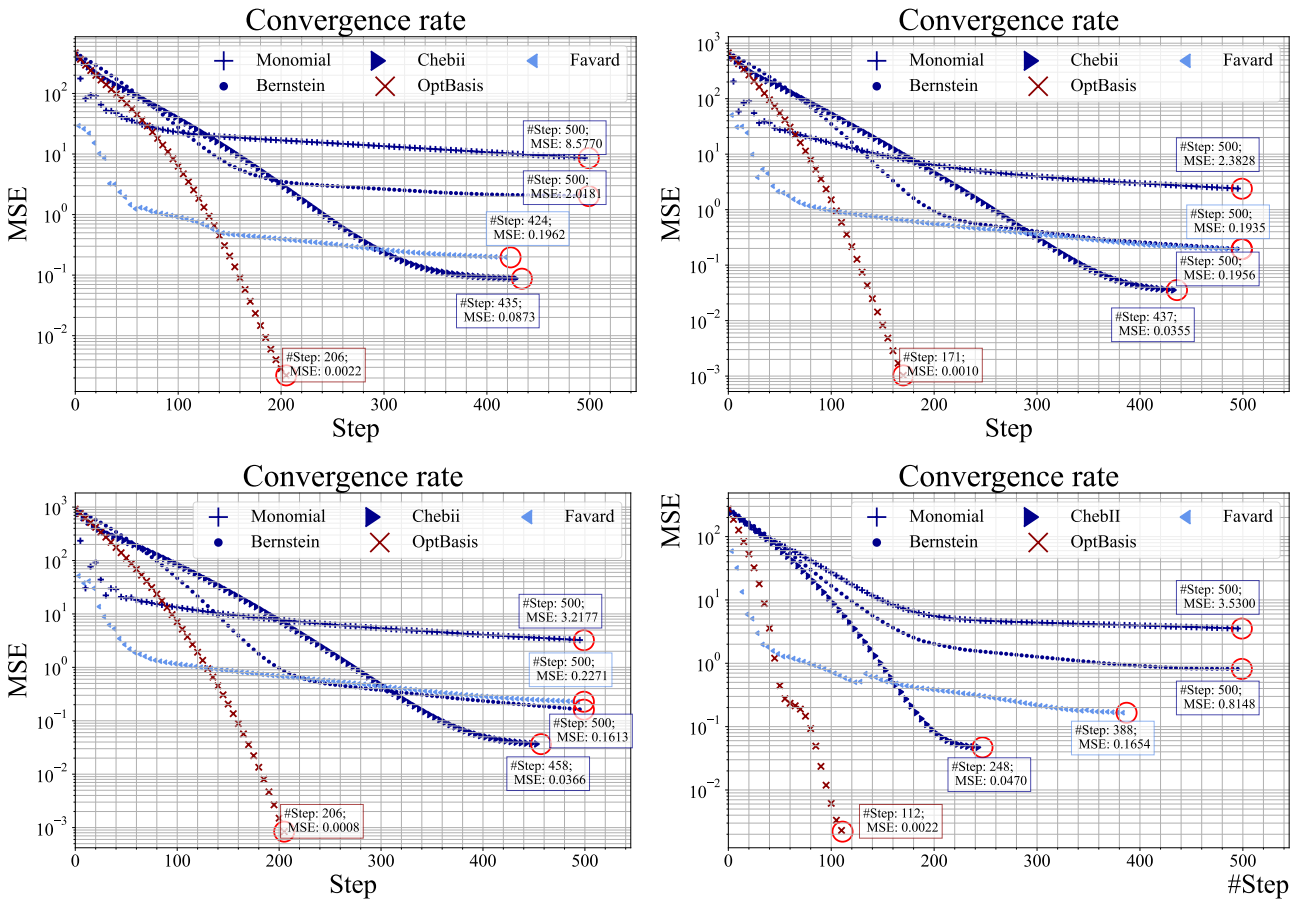

Figure 4. Visualization with more samples in the multi-channel filter learning task.

where $z = \sum_{k=0}^{K} \alpha_k g_k(\hat{P})x$.

This loss is a convex function w.r.t. α. Therefore, the gradient descents's convergence rate depends on the **Hessian matrix**'s condition number, denoted as $\kappa(H)$. When H is an identity matrix, $\kappa(H)$ reaches a minimum and leads to the best convergence rate (Boyd & Vandenberghe, 2009).

The Hessian matrix H looks like[5]:

$$H_{k_1 k_2} = \frac{\partial^2 r}{\partial \alpha_{k_1} \partial \alpha_{k_2}} = x^T g_{k_2}(\hat{P}) g_{k_1}(\hat{P}) x.$$

Wang & Zhang (2022) further write $H_{k_1 k_2}$ in the following form:

$$H_{k_1 k_2} = x^T g_{k_2}(\hat{P}) g_{k_1}(\hat{P}) x = \sum_{i=1}^{n} g_{k_1}(\mu_i) g_{k_2}(\mu_i) (U^T x)_i^2,$$

which can be equivalently expressed as a Riemann sum:

$$\sum_{i=1}^{N} g_{k_1}(\mu_i) g_{k_2}(\mu_i) \frac{F(\mu_i) - F(\mu_{i\ \ 1})}{\mu_i - \mu_{i\ \ 1}} (\mu_i - \mu_{i\ \ 1}),$$

where $F(\mu) := \sum_{\mu_i \ \ \mu} (U^T x)_i^2$. Define $f(\mu) = \frac{\mathtt{M} F(\mu)}{\mathtt{M} \mu}$, $H_{k_1 k_2}$ comes to

$$H_{k_1 k_2} = \int_{\mu=\ \ 1}^{1} g_{k_1}(\mu) g_{k_2}(\mu) f(\mu) \mathrm{d}\mu.$$

This suggests that, $\{g_k\}_{k=0}^{K}$ is an optimal basis when it is **orthonormal** w.r.t. **weight function** $f(\cdot)$. (For more about orthonormal basis, see Section 2.2.)

E.2. Wang's Method

Having write out the weight function $f(\mu)$, the optimal basis is determined. Wang & Zhang (2022) think of a regular process for getting this optimal basis, which is unreachable since eigendecomposition is unaffordable for large graphs. We summarize this process in Algorithm 3.

According to Wang & Zhang (2022), the optimal basis would be an orthonormal basis, but unfortunately, this basis and the exact form of its weight function is unattainable. As a result, they come up with a compromise by allowing the model to choose from the orthogonal Jacobi bases, which have "*flexible enough weight functions*", i.e. $(1-\mu)^a(1+\mu)^b$. The Jacobi bases are a family of polynomial bases. A specific form Jacobi basis is determined by two parameters (a, b). Similar to the well-known Chebyshev basis, the Jacobi bases have a recursive formulation, making them efficient for calculation.

[5]Note that, Wang & Zhang (2022) define g_{k_2} on $\hat{L}$ (or $\mathsf{f}\lambda_i\mathsf{g}$) while we define it on $\hat{P}$ (or $\mathsf{f}\mu_i\mathsf{g}$). They are equivalent.
