Abstract

1 Text-to-image models are trained using large datasets collected by scraping image-
2 text pairs from the internet. These datasets often include private, copyrighted,
3 and licensed material. Training models on such datasets enables them to generate
4 images with such content, which might violate copyright laws and individuals
5 privacy. This phenomenon is termed *imitation* – generation of images with rec-
6 cognizable similarity to training images. In this work we study the relationship
7 between a concept’s frequency in a dataset and the ability of a model to imitate it.
8 We seek to determine the point at which a model was trained on enough instances
9 to imitate a concept – the *imitation threshold*. We posit this question as a new
10 problem: **Finding the Imitation Threshold (FIT)** and propose an efficient approach
11 that estimates the imitation threshold without incurring the colossal cost of training
12 multiple models from scratch. We experiment with two domains – human faces
13 and art styles for which we create three datasets, and evaluate three text-to-image
14 models which were trained on two pre-training datasets. Our results reveal that the
15 *imitation threshold* of these models is in the range of 200-600 images, depending
16 on the domain and the model. The *imitation threshold* can provide an empirical
17 basis for copyright violation claims and acts as a guiding principle for providers of
18 text-to-image models that aim to comply with copyright and privacy laws.

19

1 Introduction

20 The progress of multi-modal vision-language models has been phenomenal in recent years [14, 35,
21 36, 38], much of which can be attributed to the availability of large-scale pretraining datasets like
22 LAION [44]. These datasets consist of semi-curated image-text pairs scraped from Common Crawl,
23 which leads to the inclusion of explicit, copyrighted, and licensed material [4, 9, 17, 20, 56]. Training
24 models on such images may be problematic because text-to-image models can *imitate* — the ability
25 to generate images with recognizable features — concepts from their training data [5, 49]. This
26 behavior has both legal and ethical implications, such as copyright infringements as well as privacy
27 violations of individuals whose images are present in the training data without consent. In fact, a
28 large group of artists sued Stability AI, creators of widely-used text-to-image models, alleging that
29 the company’s models generated images that distinctly replicated their artistic styles [42].

30 Previous work has focused on detecting when generated images imitate training images, and mitiga-
31 tions thereof [5, 48–50]. In particular, researchers found that duplicate images increase the chance of
32 memorization and imitation. However, the relation between a concept’s prevalence and the models’
33 ability to imitate it remains unexplored.

34 In this work, we ask **how many instances of a concept does a model need to be trained on to**
35 **imitate it?** Establishing such an *imitation threshold* is useful for several reasons. First, it provides
36 an empirical basis for copyright infringements and privacy violations claims [42, 56]. Second, it
37 acts as a guiding principle for text-to-image models providers that want to avoid such violations.
38 Finally, it reveals an interesting connection between training data statistics and model behavior, and
39 the ability of models to efficiently harness training data [6, 53]. We name this problem **FIT: Finding**
40 **the Imitation Threshold**, and provide a schematic overview of this problem in Figure 1.

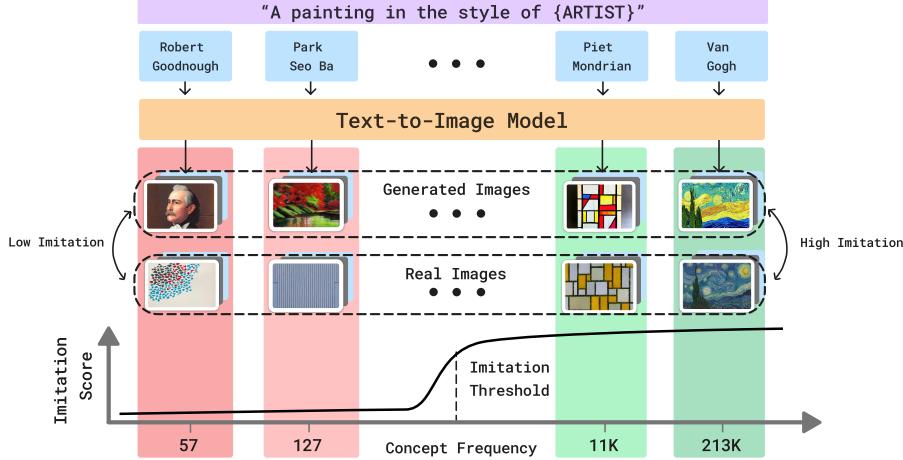

Figure 1: An overview of FIT, where we seek the *imitation threshold* – the point at which a model was exposed to enough instances of a concept that it can reliably imitate it. The figure shows four concepts (e.g., Van Gogh’s art style) that have different frequencies in the training data (213K for Van Gogh). As the frequency of a concept’s images increases, the ability of the text-to-image model to imitate it increases (e.g. Piet Mondrian and Van Gogh). We propose an efficient approach, MIMETIC², that estimates the imitation threshold without training models from scratch.

- 41 The optimal methodology to measure the imitation threshold requires training multiple models with
 42 varying number of images of a concept and measuring the ability of the counterfactual models to
 43 imitate it. However, training even one of these models is prohibitively expensive. We propose an
 44 alternative approach, **Measuring Imitation ThrEshold Through Instance Count and Comparison**
 45 (**MIMETIC²**), that estimates the threshold without incurring the cost of training models from scratch.
 46 We start by collecting a large set of concepts per domain (e.g., Van Gogh for artistic styles), and use
 47 a text-to-image to generate images for each concept. Then, we compute the imitation score of the
 48 generated images by comparing them to the training images of the respective concept, and estimate
 49 each concept’s frequency in the training data. Finally, by sorting the concepts based on frequency we
 50 estimate the imitation threshold for that domain using a *change detection* algorithm [21].
 51 Since we operate with observational data, a naive implementation may be confounded by different
 52 factors, such as the quality of the imitation scoring model on different groups within the domain, or
 53 estimating the training frequencies of concepts (e.g., simple counts of ‘Van Gogh’ in the captions
 54 results in a biased estimate since the artist may be mentioned in the caption without their work). As
 55 such, we carefully tailor MIMETIC² to minimize the impact of such confounders.
 56 Overall, we formalize a new problem – **Finding Imitation Threshold** (FIT; §3), and propose a method,
 57 **MIMETIC²**, that efficiently estimates the *imitation threshold* for text-to-image models (§5). We use
 58 our method to estimate the imitation threshold for two domains on three datasets, three text-to-image
 59 models that were trained on two pretraining datasets (§4). We find the imitation thresholds to range
 60 between 200 to 600 images, providing concrete insights on models’ imitation abilities (§6).

61 2 Background

62 **Dataset Issues and Privacy Violations** The advancement in text-to-image capabilities, largely due
 63 to big training datasets, is accompanied by concerns about the training on explicit, copyrighted, and
 64 licensed material [4] and imitating such content when generating images [9, 17, 20, 56]. For example,
 65 Birhane et al. [4] and Thiel [52] found several explicit images in the LAION dataset and Getty Images
 66 found that LAION had millions of their copyrighted images [56]. Issues around imitation of training
 67 images has especially plagued artists, whose livelihood is threatened [42, 48], as well as individuals
 68 whose face has been used without consent to create inappropriate content [2, 17].

69 **Training Data Statistics and Model Behavior** Pre-training datasets are a core factor for explaining
 70 model behavior [12]. Razeghi et al. [37] found that the in-context few-shot performance of language
 71 models (LMs) is highly correlated with the frequency of instances in pre-training datasets. Udandarao
 72 et al. [53] bolster this finding by demonstrating that the performance of multimodal models on
 73 downstream tasks is strongly correlated with a concept’s frequency in the pretraining datasets. In

74 addition, Carlini et al. [6] shows that language models more easily memorize duplicated sequences.
 75 We find a similar phenomenon: increasing the number of images of an instance increases the similarity
 76 between the generated and training images on average. Crucially, instead of measuring *memorization*,
 77 we measure *imitation*, and we use such metric to find the *imitation threshold*.

Figure 2(b): LAION2B-en images whose caption mentions ‘Mary Lee Pfeiffer’, the mother of Tom Cruise. She is not always present in the images (the rightmost image has only Tom Cruise).

78 3 Problem Formulation and Overview

79 Finding the Imitation Threshold (FIT) seeks to find the minimal number of images with some concept
 80 a model has to see during training in order to imitate it. FIT’s setup involves a training dataset
 81 $\mathcal{D} = \{(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)\}$, composed of n (image, caption) pairs. Each concept is part of
 82 a domain \mathcal{O} , such as art styles. We also assume an indicator I^j that indicates whether a concept Z^j is
 83 present in image x_i . Each concept Z^j appears $c^j = |\sum_i I^j(x_i)|$ times in the dataset \mathcal{D} . Finally, we
 84 assume a model \mathcal{M} that is trained on \mathcal{D} as a text-to-image model to predict x_i from y_i . The *imitation*
 85 *threshold* is the minimal number of images c^j with some concept Z^j from which the model \mathcal{M} is
 86 able to generate images $\mathcal{M}(p^j)$ given some prompt p^j ¹ where Z^j is recognizable as the concept.

$$\min \{k \in \{0, 1, \dots\} : I^j(\mathcal{M}_k(p^j)) = 1\}$$

87 **Optimal Approach.** Finding the *imitation threshold* is a causal question – *if model \mathcal{M} was trained*
 88 *with k' images of concept Z^j instead of k , could it generate images with this concept?* The optimal
 89 manner of answering this question is a brute force experiment [33]: For each concept Z^j , we create
 90 a dataset \mathcal{D}'_k where we vary the number of images with such concept in the training data, where
 91 $k \in \{0, 1, \dots, n\}$, and train a model \mathcal{M}'_k on each dataset. Once we find a model, \mathcal{M}'_k , that is
 92 able to generate the concept, but \mathcal{M}'_{k-1} cannot, we deem k as the *imitation threshold* for that
 93 concept. *However, due to the extreme costs of training text-to-image models, this optimal approach is*
 94 *impractical (this approach will require training $\mathcal{O}(\log n)$ models).*

95 **MIMETIC².** We propose an approach that is tractable and estimates the causal effect under certain
 96 assumptions. The key idea is to use observational data instead of training a model for different
 97 number of images for each concept. Such an approach has been previously used to answer causal
 98 questions, *inter alia*, [25, 29, 33]. Concretely, we collect several different concepts (Z^j) belonging to
 99 some domain (\mathcal{O}) while ensuring that these concepts have varying image frequencies in the training
 100 dataset \mathcal{D} . Then, we identify the frequency where model \mathcal{M} starts generating images with the concept
 101 at that frequency. We term this frequency as the *imitation threshold*.

102 To evaluate the imitation ability, we build a *concept-score* function f that returns an imitation
 103 score $f(X_t, \mathcal{M}_{P^j})$ that measures the imitation of a concept in the generated images using its
 104 training data. $X_t := x_1, \dots, x_t$ is a set of training images associated with concept Z^j . $\mathcal{M}_{P^j} :=$
 105 $\mathcal{M}(p^j)_1, \mathcal{M}(p^j)_2, \dots, \mathcal{M}(p^j)_g$ is a set of generated images created using different random seeds
 106 and a text prompt that mentions Z^j . For a domain \mathcal{O} , we collect a set of concepts Z^1, Z^2, \dots, Z^m
 107 (e.g., a list of artistic styles), estimate each concept’s frequency in data \mathcal{D} , and measure the imitation
 108 score for each concept. Sorting the concepts based on their frequencies in the dataset, and using a
 109 standard *change detection* algorithm on the imitation scores, gives us the imitation threshold for that
 110 domain. We provide the implementation details in Section 5.

111 **Assumptions.** Our approach to compute the imitation threshold makes an assumption about dis-
 112 tribution invariance in order to make the problem computationally tractable. This assumption is a
 113 standard practice when answering causal questions using observational data [33]. This assumption
 114 posits an invariance in the image distribution of each concept. Under this assumption, measuring
 115 the imitation score of a concept Z^i with a counterfactual model trained with k' images of Z^i is

¹Prompts p^j are usually different from the captions in the training data, y_i .

116 equivalent to measuring the imitation of another concept Z^j that currently has k' images in the
 117 already trained model. This helps us answer the causal question FIT seeks without training multiple
 118 models. And similar to other sample complexity works [53, 54], we also assume each image of a
 119 concept contributes equally to its learning.

120 4 Experimental Setup

Table 1: Pretraining data, models, domains, and datasets we experiment with.

Pretraining Data	Model	Domain	Dataset
LAION2B-en	SD1.1	Human Faces 🧑	Celebrities, Politicians Classical, Modern artists
	SD1.5	Human Faces 🧑	Celebrities, Politicians Classical, Modern artists
LAION-5B	SD2.1	Human Faces 🧑	Celebrities, Politicians Classical, Modern artists
		Art Style 🖨️	

Table 2: Prompts used to generate images of human faces (celebrities and politicians) and art styles. We generate 200 images per concept using different random seeds (1,000 images per concept). ‘X’ is replaced with the concept.

#	Human faces 🧑	Art style 🖨️
1.	A photorealistic close-up photograph of X	A painting in the style of X
2.	High-resolution close-up image of X	An artwork in the style of X
3.	Close-up headshot of X	A sketch in the style of X
4.	X’s facial close-up	A fine art piece in the style of X
5.	X’s face portrait	An illustration in the style of X

121 **Text-to-image Models and Training Data.** We use Stable Diffusion (SD) as the text-to-image
 122 models [38].

123 Specifically we use SD1.1, SD1.5 that were trained on LAION2B-en, a 2.3 billion image-caption
 124 pairs dataset, filtered to contain only English captions. In addition, we use SD2.1 that was trained
 125 on LAION-5B, a 5.85 billion image-text pairs dataset, which includes LAION2B-en, and other
 126 image-caption pairs from other languages [44].

127 **Domains and Concepts.** We experiment with two domains – *art styles* 🖨️ and *human faces* 🧑 that
 128 are of high importance for privacy and copyright aspects of text-to-image models. Figures 1 and 2a
 129 show examples of real and generated images of art styles and human faces.

130 We collect a two sets of artists for the art style - classical artists and modern artists, and two sets
 131 for human faces - celebrities and politicians. Then, for each set we sample 400 names that cover a
 132 wide frequency range over the pretraining data. We provide details of the sources used to collect the
 133 concepts, and sampling procedure in Appendix M. Table 1 summarizes the pretraining data, models,
 134 domains and constructed datasets we use in this work.

135 **Image Generation.** We generate images for each domain by prompting models with five prompts
 136 (Table 2). We design domain-specific prompts that encourage the concepts to occupy most of the
 137 image, which simplifies the imitation measurement. We generate 200 images per concept using
 138 different random seeds for each prompt, a total of 1,000 images per concept.

139 5 Proposed Methodology: MIMETIC²

140 We illustrate our proposed methodology in Figure 3. At a high level, for a specific domain,
 141 MIMETIC² estimates the frequency of each concept in the pretraining data (Section 5.1) and
 142 the model’s ability to imitate it (Section 5.2). We then sort the concepts based on their estimated
 143 frequencies, and find the imitation threshold using a change detection algorithm (Section 5.3).

144 5.1 Concept Frequency

145 Challenges.

146 Determining a concept’s frequency in a multimodal dataset can be achieved by employing a high-
 147 quality classifier for that concept over every image and counting the number of detected images.
 148 However, given the scale of modern datasets with billions of images, this approach is expensive
 149 and time consuming. Instead, we make a simplifying assumption that a concept is present only if
 150 the image’s caption mentions it. While this assumption does not hold in general, it is a reasonable
 151 simplification for the domains we focus on. We further discuss this assumption and provide sup-
 152 porting evidence for its accuracy in Appendix D. In addition, concepts often do not appear in the
 153 corresponding images, even when they are mentioned in captions. For instance, Figure 2b showcases
 154 images whose captions contain “Mary Lee Pfeiffer”, but her image does not always include her. On
 155 average, we find that concepts occur only in 60% of the images whose captions mention the concept.

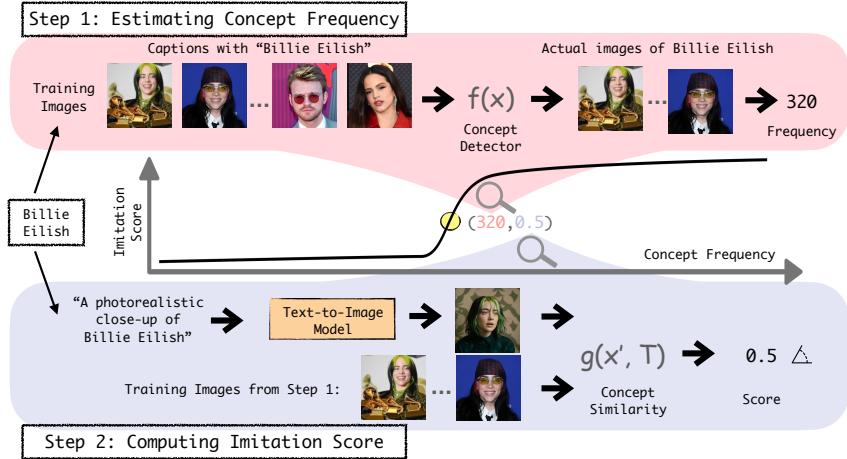

Figure 3: Overview of MIMETIC²'s methodology to estimate FIT. In Step 1, we estimate the frequency of each concept in the pretraining data by obtaining the images (x) that contain the concept of interest. In Step 2, we use the images of each concept and compare them to the generated images to measure imitation (using g that receives reference images T , and generated image x'). We repeat this process for each concept to generate the imitation graph, and then determine the *imitation threshold* with a detection change algorithm.

156 **Estimating Concept Frequency** Due to the challenges described above, we start by retrieving all
 157 images whose captions mention the concept of interest and filter out the ones that do not have that
 158 concept, as detected by a classifier. We retrieve these images using WIMBD [12], a search tool based
 159 on a reverse index that efficiently finds documents (captions) from LAION containing the search
 160 query (concept). In addition, for each concept, we construct a set of high quality reference images.
 161 For example, a set of images with only the face of a single person (e.g., Brad Pitt). We collect these
 162 images automatically using a search engine, followed by a manual verification to vet the images (see
 163 Appendix E for details). Overall, we collect up to ten reference images per concept. These images are
 164 used as gold reference for automatic detection of these concepts in the images from the pretraining
 165 datasets.

166 Next, to classify whether a candidate image from the pretraining data contains the concept of interest,
 167 we embed the candidate image and the concept’s reference images using an image encoder and
 168 measure the similarity between the embeddings. We use a face embedding model [11] for faces and
 169 an art style embedding model [51] for art style. If the similarity between a candidate image and any
 170 of the reference images is above some threshold, we consider that image to contain that concept. This
 171 threshold is established by measuring the similarity between images of the same concepts and images
 172 of different concepts which maximizes the true positive, and minimizes false positive. We provide
 173 additional details on the exact thresholds per dataset and how to find them in Appendices F and G.

174 Finally, we employ the classifier on all candidate images corresponding to a concept, and take those
 175 that are classified as positive. For each concept, we randomly retrieve up to 100K images whose
 176 captions mention that concept. We use the ratio of positive predictions from the retrieved candidate
 177 images and multiply it by the total caption counts of the concept in the dataset and use that as the
 178 concept frequency estimate. For concepts with less than 100K candidate images, we simply use all
 179 the images that are positively classified. Note that several URLs in the LAION datasets are dead,
 180 a common phenomenon for URL based datasets (“link rot” [7, 23]). On average, we successfully
 181 retrieved 74% of the candidate images.

182 5.2 Computing Imitation Score

183 **Challenges.** Computing the imitation score entails determining how similar a concept is in a generated
 184 image compared to its source images from the training data. Several approaches were proposed to
 185 accomplish this task, such as FID and CLIPScore [15, 16, 34, 39, 41]. To measure similarity, these
 186 approaches compute the similarity between the distributions of the embeddings of the generated and
 187 training images of a concept. The embeddings are obtained using image embedders like Inception
 188 model in case of FID and CLIP in case of CLIPScore. These image embedders often perform
 189 reasonably well in measuring similarity between images of common objects which constitutes most
 190 of their training data. However, they cannot reliably measure the similarity between two very similar

Table 3: *Imitation Thresholds* for human face and art style imitation for the different text-to-image models and datasets we experiment with.

Pretraining Dataset	Model	Human Faces 🧑		Art Style 🎨	
		Celebrities	Politicians	Classical Artists	Modern Artists
LAION2B-en	SD1.1	364	234	112	198
	SD1.5	364	234	112	198
LAION-5B	SD2.1	527	369	185	241

191 concepts like the faces of two individuals or art style of two artists [1, 15, 19, 51]. Therefore,
 192 MIMETIC² uses domain specific image embedders to measure similarity between two concepts. It
 193 uses a face embedding model [11] for measuring face similarity and an art style embedding model
 194 [51] for measuring art style similarity. Even the specific choice of these models is crucial. For
 195 instance, in early experiments we used Facenet [43], and observe it struggles to distinguish between
 196 individuals of certain demographics, causing drastic differences in the imitation scores between
 197 demographics. We provide more details on these early experiments in Appendix L, and show that our
 198 final choice of embedding models work well on different demographics.

199 **Estimating Imitation Score** To measure imitation we embed the generated images and training
 200 images of a concept (obtained from Section 5.1) using the concept specific image embedder. For
 201 measuring face imitation, we use InsightFace, a face embedding model [10] that extracts the individ-
 202 ual’s face from an image and generates an embedding for it. For measuring art style imitation, we use
 203 CSD, an art style embedding model [51] that generates an embedding for an image of an art work.
 204 We obtain the embeddings of the generated and training images for both the domain, and measure
 205 imitation by computing the cosine similarity between them.

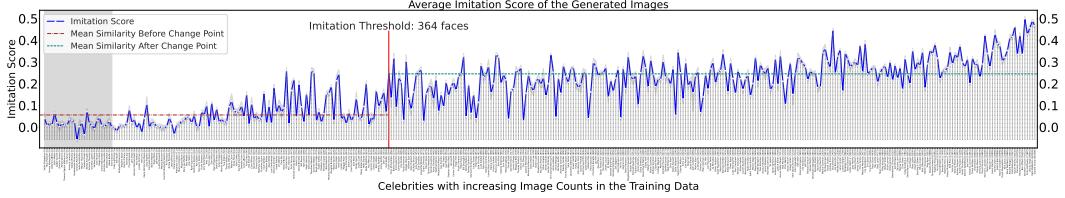

206 To ensure that the automatic measure of similarity correlates with human perception, we also conduct
 207 experiments with human subjects and measure the correlation between the similarities obtained
 208 automatically and in the human subject experiments. We find a high correlation between the two
 209 measures of similarity (§C in Appendix).

210 5.3 Detecting the *Imitation Threshold*

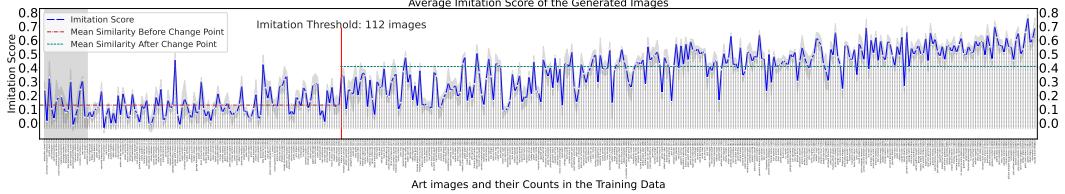

211 After computing the concept frequencies and the imitation scores for each concept, we sort them
 212 in an ascending order of their image counts. This generates a sequence of points, each of which
 213 is a pair of image counts and imitation score of a concept. We apply a standard change detection
 214 algorithm, PELT [21], to find the image frequency where the imitation score significantly changes.
 215 Change detection is a classic statistical problem for which the objective is to find the points where the
 216 mean value of a stochastic time-series signal changes significantly. Several algorithms were proposed
 217 for change detection [55]. We choose PELT because of its linear time complexity in computing
 218 the change point. We choose the first change point as the imitation threshold (see Appendix I for
 219 details about all change points). The application of change detection assumes that increasing the
 220 image counts beyond a certain threshold leads to a large jump in the imitation scores, and we find
 221 this assumption to be accurate in our experimental results.

222 6 Results: The *Imitation Threshold*

223 We apply MIMETIC² to estimate the imitation threshold for each model-data pair, and present
 224 the results in Table 3. The imitation thresholds for SD1.1 on celebrities and politicians are 364
 225 and 234 respectively. And the imitation thresholds for classical and modern artists are 112 and
 226 198 respectively. Interestingly, SD1.1 and SD1.5 have the same thresholds for all the four datasets.
 227 Notably, both SD1.1 and SD1.5 are trained on LAION2B-en. The imitation thresholds for SD2.1,
 228 which is trained on the larger LAION-5B dataset is higher than the thresholds for SD1.1 and SD1.5.
 229 The imitation threshold for SD2.1 on celebrities and politicians are 527 and 369 respectively, and
 230 on classical and modern artists are 185 and 241 respectively. We hypothesize that the difference in
 231 performance of SD2.1 and SD1.1 is due to the difference in their text encoders [32]. (The difference
 232 in performance of SD2.1 and SD1.5 was also reported by several users on online forums.) To test this
 233 hypothesis, we compute the imitation thresholds for politicians for all SD models in series 1: SD1.1,
 234 SD1.2, SD1.3, SD1.4, and SD1.5. We found that the imitation thresholds for all these models are
 235 almost the same. We present the graphs for all these models in Appendix H.

(a) **Human Face Imitation.** The imitation threshold is detected at **364 faces**.

(b) **Art Style Imitation.** The imitation threshold is detected at **112 images**.

Figure 4: **Human Face** and **Art Style** imitation graphs of SD1.1 for the celebrity and classical artists datasets. The x-axis represents the sorted counts from the training set (and each concept), and the y-axis represents the similarity between the training and generated images. Concepts with zero image frequencies are shaded with light gray. We show the mean and variance over the five generation prompts. The red vertical line indicates the imitation threshold, and the horizontal green line represents the similarity threshold.

236 Note that celebrities have a higher imitation threshold than politicians. We hypothesize this happens
 237 due to inherent differences in the data distribution in these two datasets, which makes it harder to
 238 learn the concept of celebrities than politicians. To test this hypothesis, we compute the average
 239 number of images with a single person for people with less than 1,000 images in the pretraining
 240 dataset. We find that politicians have about twice the number of single person images compared to
 241 celebrities. As such, images that have only the concept of interest increase the ability of the model to
 242 learn from them, thus lowering the imitation threshold. We observe a similar pattern with artists: the
 243 imitation threshold for modern artists is higher than for classical artists.

244 We also present the plots of the imitation scores as a function of the image frequencies of the concepts
 245 in the three datasets. Figures 4a and 4b show the imitation graphs of celebrities and art styles,
 246 respectively for SD1.1. The x-axis describes the sorted concept frequency and the y-axis describes
 247 the imitation score (averaged over the five image generation prompts). We showcase the graphs for
 248 the other models and domain in Appendix J, which follow similar trends.

249 In Figure 4a, we observe that the imitation scores for individuals with low image frequencies are
 250 close to 0 (left side), and increase as the image frequencies move towards the right side. The highest
 251 similarity is 0.5 and it is for individuals in the rightmost region of the plot. We observe a low variance
 252 in the imitation scores across prompts. We also note that the variance does not depend on the image
 253 frequencies (0.0003 ± 0.0005) – indicating that the performance of the face embedding model does
 254 not depend on the popularity of the individual.

255 Similarly, in Figure 4b, we observe that imitation scores for art styles with low image frequencies
 256 are close to 0.2 (left side), and increase as the image frequencies move towards the right side. The highest
 257 similarity is 0.76 and it is for the artists in the rightmost region of the plot. We also observe a
 258 low variance across the generation prompts, and the variance does not depend on the image frequency
 259 of the artist (0.003 ± 0.003).

260 **Results Discussion.** Overall, we observe that the imitation thresholds are similar across the different
 261 image generation models and pretraining datasets, but are domain dependent. They show little
 262 variance across various image generation prompts. And most importantly, the thresholds computed
 263 by MIMETIC² have a high degree of agreement with human perception of imitation.

264 We also note the presence of several outliers in both plots, that can be categorized into two types:
 265 (1) concepts whose image counts are smaller than the imitation threshold, but their imitation scores
 266 are considerably high; and (2) concepts whose image counts are higher than the imitation threshold,
 267 but their imitation scores are low. As such, from a privacy perspective, the first kind of outliers are
 268 more crucial than the second ones. This is because the imitation threshold should act as guarantors of
 269 privacy. It would be fine if a concept with a frequency higher than the threshold is not imitated by

270 the model (false positive), but it would be a privacy violation if a model can imitate a concept with
271 frequency lower than the threshold (false negative). Therefore, it is preferable to underestimate the
272 imitation threshold to minimize false negatives. Upon further analysis, we find that the actual concept
273 frequencies of *all the false negative outliers* is much higher than what MIMETIC² counts, primarily
274 due to aliases of names, thereby alleviating the privacy violation concerns (see Appendix B).

275 We also note that the range of the imitation scores of different domains have different y-axis scales.
276 This is due to the difference in embedding models used in both cases. The face embedding model can
277 distinguish between two faces much better than the art style model can distinguish between two styles
278 (see Appendices F and G), and therefore the scores for the concepts on the left side of the imitation
279 threshold is around 0 for face imitation and 0.2 for style imitation. The face embedding model also
280 gives lower score to the faces of the same person, compared to the style embedding model’s score for
281 images of the same art styles, and therefore the highest scores for face imitation is 0.5, whereas it is
282 0.76 for art style imitation. However, the absolute values on the y-axis do not matter for estimating
283 the imitation threshold as long as the trend is similar, which is the case for both domains.

284 7 Discussion and Limitations

285 **Equal Effect Assumption.** An assumption in the formulation of MIMETIC² is that every image
286 of a concept contributes equally to the learning of the concept. However, not all images are created
287 equal. While analyzing celebrities’ images for instance, we often find that individuals whose images
288 are mostly close-ups of a single person have a higher imitation score than individuals whose images
289 are cluttered by multiple people, since concept-centered images enhance their learnability.

290 We hope to investigate this assumption in future work, and address this, and other potential con-
291 founders.

292 **Factors Affecting the Imitation Threshold.** In this work we attribute the imitation of a concept to
293 its image count. However, image count – although a crucial factor – is not the only factor that affects
294 imitation. Several other factors like image resolution, alignment between images and their captions,
295 the variance between images of a concept, etc., may affect imitation.

296 Several training time factors like the optimization objective, learning schedule, training data order,
297 model capacity, model architecture also affect the imitation threshold. We discuss the difference
298 in the imitation thresholds of SD1.1, SD1.5 and SD2.1 is attributed to the difference in their text
299 encoders. SD1.1 and SD1.5 use CLIP model [35] as their text encoder and SD2.1 uses OpenCLIP
300 [18] as its text encoder. Note that while these may impact the behavior of the model, our work is
301 interested in a particular model-data pair, for which we investigate. We do not claim that our results
302 would generalize to other models, or datasets, and leave the question on how to FIT that generalize
303 across models to future work.

304 8 Conclusions

305 Text-to-image models can imitate their training images [5, 49, 50]. This behavior is potentially
306 concerning because these models’ training datasets often include copyrighted and licensed images.
307 Imitating such images would be grounds for violation of copyright and privacy laws. In this work,
308 we seek to find the number of instances of a concept that a text-to-image model needs in order to
309 imitate it – the *imitation threshold*. We posit this as a new problem, **Finding the Imitation Threshold**
310 (**FIT**) and propose an efficient method for finding such threshold. Our method, MIMETIC², utilizes
311 pretrained models to estimate the imitation threshold for human face and art style imitation using three
312 text-to-image models trained on two different pretraining datasets. We find the imitation threshold of
313 these models to be in the range of 200-600 images depending on the setup. As such, on the domains
314 we evaluate in this work trained on our models, our results indicate that models cannot replicate
315 concepts that appear less than 200 times in the training data.

316 By estimating the imitation threshold, we provide insights on successful concepts imitation based on
317 their training frequencies. Our results have striking implications on both the text-to-image models
318 users and providers. These thresholds can inform text-to-image model providers what concepts are in
319 risk of being imitated, and on the other hand, serve as a basis for copyright and privacy complaints.

(a) **Outlier Category 1.** *Thandiwe Newton* is aliased as *Thandie Newton*, which leads to lower counts of her images in the dataset since MIMETIC² only collects images whose caption mentions *Thandiwe Newton*.

(b) **Outlier Category 2.** Most of the images whose captions mention *Cacee Cobb* have multiple people in them, only 6 images have her as the only person, leading to a low imitation score in generated images.

Figure 5: Examples of the two categories of outliers. The top and bottom rows show the real and SD1.1 generated images respectively. The images were generated using the following prompt: “a photorealistic close-up image of [name].”

518 A Additional Related Work

519 **Imitation in Text-to-Image Models:** Carlini et al. [5], Somepalli et al. [49] demonstrated that
 520 diffusion models can memorize and imitate duplicate images from their training data (they use
 521 ‘replication’ to refer to this phenomenon). Casper et al. [8] corroborated the evidence by showing
 522 that these models imitated art styles of 70 artists with high accuracy (as classified by a CLIP model)
 523 when prompted to generated images in their styles (a group of artists also sued Stability AI claiming
 524 that their widely-used text-to-image models imitated their art style, violating copyright laws [42]).
 525 However, these works did not study how much repetition of a concept’s images would lead the model
 526 to imitate them. Studying this relation is important as it serves to guide institutions training these
 527 models who want to comply with copyright and privacy laws.

528 **Mitigation of Imitation in Text-to-Image Models:** Several works proposed to mitigate the
 529 negative impacts of text-to-image models. Shan et al. [48] proposed GLAZE that adds imperceptible
 530 noise to the art works such that diffusion models are unable to imitate artist styles. A similar approach
 531 was proposed to hinder learning human faces [47]. Wang et al. [57] proposed adding noise to training
 532 images, which can be used to detect if a model has been trained on those images. Lu et al. [28]
 533 propose pushing the generated images away from the distribution of training images to minimize
 534 mitigation. Gandikota et al. [13], Kumari et al. [22] proposed algorithms to remove specific styles,
 535 explicit content, and other copyrighted material learned by text-to-image models. On a related note,
 536 Xie et al. [59] proposed Diffusion-ReTrac that finds training images that most influenced a generated
 537 image, and thereby provide a fair attribution to training data contributors.

538 B Analysis: Investigating Outliers

539 The imitation score plots in the previous section, while showcasing a clear trend, have several outliers.
 540 In this section, we analyze the imitation scores for such outliers, where we present two examples in
 541 Figure 5 (additional outliers can be found in Figures 28 and 29 in the appendix).

542 **Low Image Counts and High Imitation Scores.** Figure 5a shows an example of such a case:
 543 *Thandiwe Newton*’s image count is 172 in LAION2B-en, lower than the *imitation threshold* for
 544 celebrities: 364. However, her imitation score of 0.26 is much higher than those of neighboring
 545 celebrities with similar image counts (with scores of 0.01 and 0.04). Further investigation reveals that
 546 *Thandiwe Newton* is also known as *Thandie Newton*. Since this alias may also be used to describe
 547 her in captions, MIMETIC² may have underestimated her image counts. We repeat the process
 548 for estimating the image counts with the new alias, and find that *Thandie Newton* appears in 12,177
 549 images, bringing the cumulative image count to 12,349, which significantly surpasses the established
 550 imitation threshold. The two aliases, whose total image count is considerably higher than the imitation
 551 threshold, differ by only a single letter and are similarly represented by the model’s encoder (cosine
 552 similarity of 0.96), which explains the high imitation score. We find that most of the celebrities from
 553 the first kind of outliers are also known by other names which lead to underestimating their image
 554 counts. For example, *Belle Delphine* (394 images) also goes by *Mary Belle* (310 images, for a total
 555 of 704, and *DJ Kool Herc* (492 images) also goes by *Kool Herc* (269 images, for a total of 761).

556 The aliases explanation also largely explains the outliers in art style imitation. For instance, artist
 557 *Gustav Adolf Mossa* (19 images) also goes by just *Mossa* (15850 images), artist *Nicolas Toussaint*

558 *Charlet* (78 images) also goes by just *Nicolas Toussaint* (533 images), and artist *Wilhelm Von
559 Kaulbach* (81 images) also goes by *Von Kaulbach* (978 images). See Figures 30 and 31 in the
560 appendix for the real and generated images of these artists.

561 **High Image Counts and Low Imitation Scores** Several celebrities have higher image counts than
562 the imitation threshold, but low imitation scores. Unlike the previous case, we were unable to find a
563 common cause that explains all these outliers. However, we find explanations for specific cases. For
564 example, a staggering proportion of the training images for several celebrities have multiple people
565 in them. For example, out of the 706 total images of *Cacee Cobb*, only 6 images have her as the only
566 person in the image (see Figure 5b). Similarly, out of 1,296 total images of *Sofia Hellqvist*, only
567 67 images have her as the only person and out of the 472 total images of *Charli D' Amelio*, only
568 82 images have him as the only person. We hypothesize that having multiple concepts in an image
569 impedes the proper mapping of the concept's text embedding to its image embedding, which can
570 explain the low imitation score for these concepts. We leave it to future work to further study the
571 connection between the number of concepts in an image and models' ability to imitate these concepts.

572 C Human Perception Evaluation.

573 To determine if the automatic measure of similarity between the generated and training images
574 correlate with human perception, we conduct experiments with human subjects. We asked the
575 participants to rate generated images on the Likert scale [26] of 1-5 based on their similarity to real
576 images of celebrities, the same ones used for measuring the imitation score. The participants were
577 not informed of the research objective of this work.

578 For human face imitation, we conduct this study with 30 participants who were asked to rate 10
579 (randomly selected) generated images for a set of 40 celebrities. To determine the accuracy of
580 the imitation threshold estimated by MIMETIC², we select the celebrities such that half of them
581 have image frequencies below the threshold and the other half above it. We measure the Spearman
582 correlation [60] between the imitation scores computed by the model and the ratings provided by the
583 participants. Due to the variance in perception, we normalize the ratings from the participants before
584 computing the average rating for generated images of a celebrity. The Spearman correlation between
585 human perception and the imitation scores is **0.85**, signifying a high quality imitation estimator. We
586 also measure the agreement between the imitation threshold that MIMETIC² estimates and the
587 threshold that humans perceive. For this purpose, we convert the human ratings to binary values
588 and treat it as the ground truth (any rating of 3 or more is treated as 1 and less than 3 is treated as
589 0). As for the MIMETIC²' predictions, we construct another set of the same size that has a zero
590 for a celebrity whose concept frequency is lower than the imitation threshold, and 1 otherwise. To
591 measure the agreement, we compute the element-wise dot product between these two sets. We find
592 the agreement to be 82.5%, signifying a high degree of agreement for MIMETIC²'s automatically
593 computed threshold.

594 For art style imitation, we conduct this study with an art expert due to the complexity of detecting
595 art styles. The participant was asked to rate five generated images for 20 art styles, half of which
596 were below the imitation threshold and the other half, above the threshold. We find the Spearman
597 correlation between the two quantities to be **0.91** – demonstrating that our imitation scores are highly
598 correlated with an artist's perception of style similarity. Similar to the previous case, we measure
599 the agreement of the imitation threshold, which we find to be 95% – signifying a high degree of
600 agreement for MIMETIC²'s computed threshold.

601 D Caption Occurrence Assumption

602 For estimating the concept's counts in the pretraining dataset we make a simplifying assumption: a
603 concept can be present in the image only if it is mentioned in a paired caption. While this assumption
604 isn't true in general, we show that for the domains we experiment with, it mostly holds in practice.

605 For this purpose, we download 100K random images from LAION2B-en, and run the face detection
606 (used in Section 5) on all images, and count the faces of the ten most popular celebrities in our
607 sampled set of celebrities. Out of the 100K random images, about 57K contain faces. For each
608 celebrity, we compute the similarity between all the faces in the downloaded images and the faces in
609 the reference images of these celebrities. If the similarity is above the threshold of 0.46, we consider
610 that face to belong to the celebrity (this threshold is determined in Appendix F to distinguish if two
611 images are of the same person or not). Table 4 shows the number of faces we found for each celebrity

Table 4: Face count of the ten most popular celebrities in 100K random LAION images. The small percentage of the images we miss shows that our assumption of counting the images where a concept is mentioned in the caption is empirically reasonable.

Celebrity	Face Count in 100K images	Face Count in Images with Caption Mention	Percentage of Missed Images	Number of Missed Images
Floyd Mayweather	1	0	0.001%	23K
Oprah Winfrey	2	0	0.002%	46K
Ronald Reagan	6	3	0.003%	69K
Ben Affleck	0	0	0.0%	0
Anne Hathaway	0	0	0.0%	0
Stephen King	0	0	0.0%	0
Johnny Depp	9	1	0.008%	184K
Abraham Lincoln	52	1	0.051%	1.17M
Kate Middleton	34	1	0.033%	759K
Donald Trump	16	0	0.016%	368K

612 in the 100K random LAION images. We also show the face counts among these images whose
 613 captions mention the celebrity. We find that 1) the highest frequency an individual appears in an
 614 image without their name mentioned in the caption is 51 (*Abraham Lincoln* is mentioned once in the
 615 caption and he appears a total of 52 times), and 2) the highest percentage of image frequency that we
 616 miss is 0.051%, and 3) most of the other miss rates are much smaller (close to 0). Such low miss
 617 rates demonstrate that our assumption of counting images when a concept is mentioned in the caption
 618 is empirically reasonable.

619 We also note that this assumption would fail if we were computing image frequencies for concepts
 620 that are so widely common that one would not even mention them in a caption, for example, phone,
 621 shoes, or trees.

622 E Collection of Reference Images

623 E.1 Collection of Reference Images for Human Faces Domain

624 The goal of collecting reference images is to use them to filter the images of the pretraining dataset.
 625 These images are treated as the gold standard reference images of a person and images collected from
 626 pretraining dataset are compared to these images. If the similarity is higher than a threshold then that
 627 image is considered to belong to that person (see Section 5 for details). We describe an automatic
 628 manner of collecting the reference images. The high level idea is to collect the images from Google
 629 Search and automatically select a subset of those images that are of the same concept (same person’s
 630 face or same artist’s art). Since this is a crucial part of the overall algorithm, we manually vet the
 631 reference images for all the concepts to ensure that they all contain the same concept.

632 **Collection of Reference Images for Human Face Imitation:** We collect reference images for
 633 celebrities and politicians using a three step process (also shown in Algorithm 1):

- 634 **1. Candidate set:** First, we retrieved the first hundred images by searching a person’s name on
 635 Google Images. We used SerpAPI [46] as a wrapper perform the searches.
- 636 **2. Selecting from the candidate set:** Images retrieved from the internet are noisy and might not
 637 contain the person we are looking for. Therefore we filter images that contain the person from
 638 the candidate set of images. For this purpose, we use a face recognition model. We embed all the
 639 faces in the retrieved images using a face embedding model and measure the cosine similarity
 640 between each one of them. The goal is to search for a set of faces that belong to the same person
 641 and therefore will have a high cosine similarity to each other.

642 One strategy is for the faces to form a graph where the vertices are the face embeddings and the
 643 edges connecting two embeddings have a weight equal to the cosine similarity between them, and
 644 we select a dense k-subgraph [24] from this graph. Selecting such a subgraph means finding a
 645 mutually homogeneous subset. We can find the vertices of this dense k-subgraph by cardinality-
 646 constrained submodular function minimization [3, 30] on a facility location function [3]. We run
 647 this minimization and select a subset of images (at least of size ten) that has the highest average
 648 cosine similarity between each pair of images.

649 3. **Manual verification:** Selecting the faces with the highest average similarity is not enough. This
 650 is because in many cases the largest set of faces in the candidate set are not of the person we look
 651 for, but for someone closely associated with them, in which case, the selected images are of the
 652 other person. For example, all the selected faces for *Miguel Bezos* were actually of *Jeff Bezos*.
 653 Therefore, we manually verify all the selected faces for each person. In the situation where the
 654 selected faces are wrong, we manually collect the images for them, for example, for Miguel Bezos.
 655 We collect at least 5 reference images for all celebrities.

Algorithm 1: Collection of Reference Images for Human Face Imitation

Input: Person’s name P
Output: Verified Set of Images of P

```

1  $images \leftarrow \text{SerpAPI}(P)$ ;                                 $\triangleright$  Retrieve initial image set using SerpAPI
2  $candidateSet \leftarrow \text{Submodular\_Minimization}(images)$ ;    $\triangleright$  Select candidate set using submodular
   minimization
3  $verifiedSet \leftarrow \text{manualVerification}(candidateSet)$ ;       $\triangleright$  Manually verify the candidate set
  
```

656 **Collection of Reference Images for Art Styles** We collect reference images for each artist (each
 657 artist is assumed to have a distinct art style) from Wikiart, the online encyclopedia for art works.
 658 Since the art works of each artist were meticulously collected and vetted by the artist community, we
 659 consider all the images collected from Wikiart as the reference art images for that artist.

660 F Implementation Details of MIMETIC² for Human Face Imitation

661 F.1 Filtering of Training Images

662 Images whose captions mention the concept of interest often do not contain it (as shown with Mary-
 663 Lee Pfeiffer in Figure 2b). As such, we filter images where the concept does not appear in the image,
 664 which we detect using a dedicated classifier. In what follows we describe the filtering mechanism.

665 Collecting Reference Images:

666 We collect reference images for each person using SerpAPI as described in Appendix E. These images
 667 are the gold standard images that we manually vet to ensure that they contain the target person of
 668 interest (see Appendix E for the details). We use the reference images to filter out the images in the
 669 pretraining dataset that are not of this person. Concretely, for each person we use a face embedding
 670 model [10] to measure the similarity between the faces in the reference images and the faces in the
 671 images from the pretraining datasets whose captions mention this person. If the similarity of a face in
 672 the pretraining images to any of the faces in the reference images is above a certain threshold, that
 673 face is considered to belong to the person of interest. We determine this threshold to distinguish faces
 674 of the same person from faces of different persons in the next paragraph. Note that this procedure
 675 already filters out any image that does not contain a face, because the face embedding model would
 676 only embed an image if it detects a face in that image.

677 **Determining Filtering Threshold:** The next step is to determine the threshold for which we
 678 consider two faces to belong to the same person. For this purpose, we measure the similarity between
 679 pairs of faces of the same person and the similarity between pairs of faces of different persons. Since
 680 the reference images for each person is manually vetted to be correct, we use these images for this
 681 procedure. We plot the histogram of the average similarity between the faces of the same person
 682 (blue colored) and the similarity between faces of different persons (red colored) in Figure 6. We see
 683 that the two histograms are well separated, with the lowest similarity value between the faces of the
 684 same person being 0.56 and the highest similarity value between the faces of different persons being
 685 0.36. Therefore any threshold value between 0.36 and 0.56 can separate two faces of the same person,
 686 from the faces of different people. In our experiments, we use the midpoint threshold of 0.46 (true
 687 positive rate (tpr) of 100%; false positive rate (fpr) of 0%) to filter any face in the pretraining images
 688 that do not belong to the person of interest. The filtering process gives us both the image frequency a
 689 person in the pretraining data, and the pretraining images that we compare the faces in the generated
 690 images to measure the imitation score.

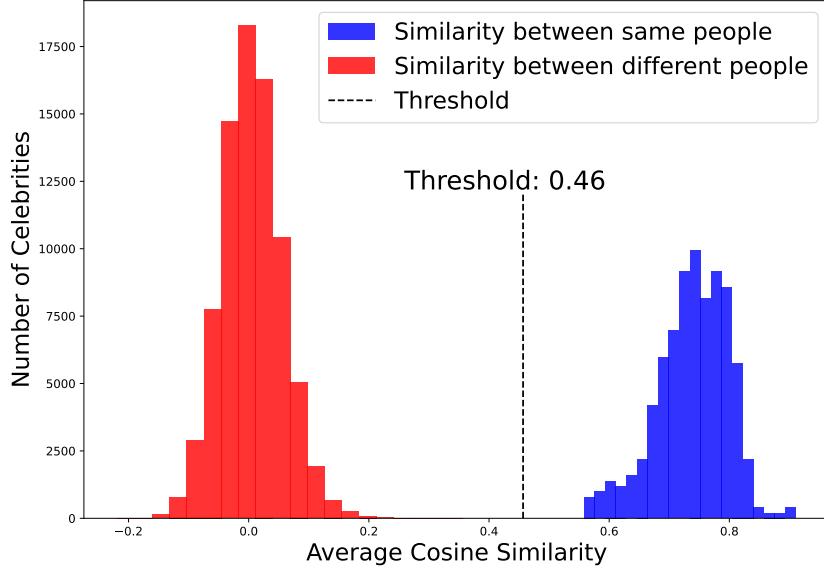

Figure 6: Average cosine similarity between the faces of the same people (blue colored) and of the faces of different people (red colored), measured across the reference images of the celebrities.

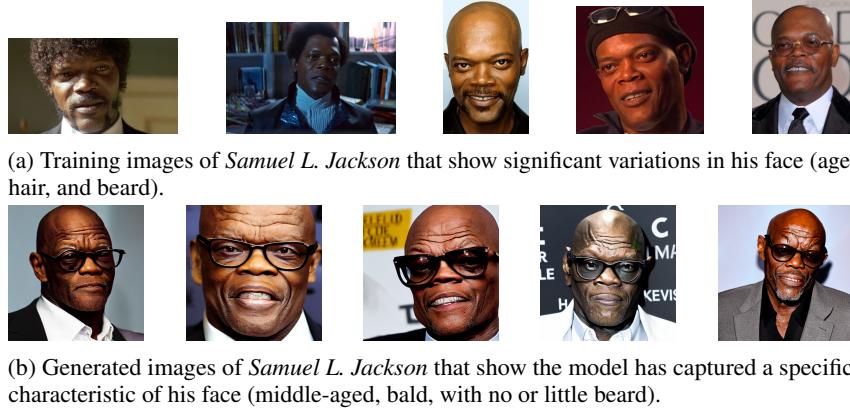

Figure 7: Real and generated images of *Samuel L. Jackson*.

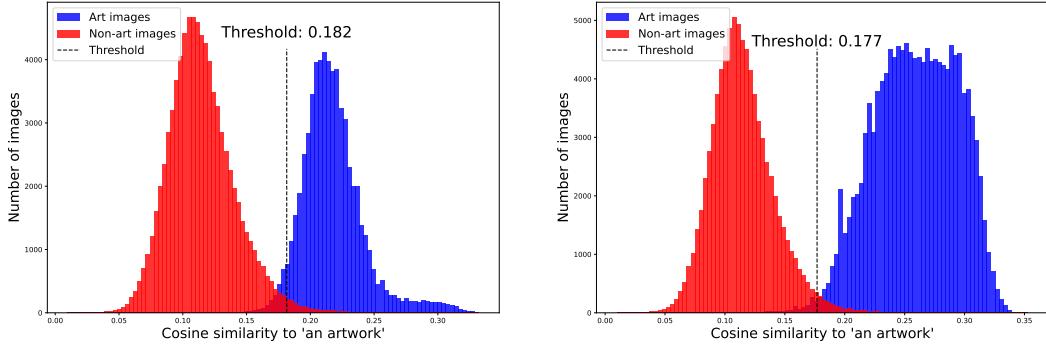

691 F.2 Measurement of Imitation Score

692 To measure the imitation between the training and generated images of a person, we compute the
 693 cosine similarity between the face embeddings of the faces in their generated images and their filtered
 694 training images from the previous step. However, measuring the similarity using all the pretraining
 695 images can underestimate the actual imitation. This is because several individuals have significant
 696 variations in their faces in the pretraining images and the text-to-image model does not capture all
 697 these variations. For example, consider the pretraining images of *Samuel L. Jackson* in Figure 7a.
 698 These images have significant variations in beard, hair, and age. However, when the text-to-image
 699 model is prompted to generate images of *Samuel L. Jackson*, the generated images in Figure 7b
 700 only show a specific facial characteristic of him (middle-aged, bald, with no or little beard). Since
 701 MIMETIC²'s goal is not to measure if a text-to-image model captures all the variations of a person,
 702 we want to reward the model even if it has only captured a particular characteristic (which it has in
 703 this case of *Samuel L. Jackson*). Therefore, instead of comparing the similarity of generated images
 704 to all the training images, we compare the similarity to only the ten training images that have the
 705 highest cosine similarity to the generated images on average.

706 **G Implementation Details of MIMETIC² for Art Style Imitation**

707 **G.1 Filtering of Training Images**

708 For art style imitation, we consider each artist to have a unique style. We collect the images from the
 709 pretraining dataset whose captions mention the name of the artist whose art style imitation we want to
 710 measure. Similar to the case of human face imitation, we want to filter out the pretraining images of
 711 an artist that in reality was not created by that artist, but their captions mention them. We implement
 712 the filtering process in two stages. In the first stage, we filter out non-art images in the pretraining
 713 dataset (note that the captions of these images still mention the artist, but the images themselves are
 714 not art works) and in the second stage we filter out art works of other artists (the captions of these
 715 images mention the artist of interest and the image itself is also an art work, but by a different artist).
 716 The implementation details for each stage is as follows:

(a) Histogram of the cosine similarity of embeddings of art and non-art images to embeddings of ‘an artwork’ for classical artists.

(b) Histogram of the cosine similarity of embeddings of art and non-art images to embeddings of ‘an artwork’ for modern artists.

Figure 8: The first filtering step involves determining the threshold to distinguish between art and non-art images from the pretraining images, for which we compare the similarity of the image’s embedding to the embedding of the text “an artwork”.

717 **Filtering Non-Art Images:** To filter non-art images from the pretraining dataset, we use a classifier
 718 that separates art images from non-art images. Concretely, we embed the pretraining images using a
 719 CLIP ViT-H/14 [18] image encoder and measure the cosine similarity of the image embeddings and
 720 the text embeddings of the string ‘*an artwork*’, embedded using the text encoder of the same model.
 721 Only when the similarity between the embeddings is higher than a threshold described below, we
 722 consider those pretraining images as an artwork. To determine this threshold, we choose a similarity
 723 score that separates art images from non-art images. We use the images from the Wikiarts dataset
 724 [40] as the (positive) art images and MS COCO dataset images [27] as the (negative) non-art images.
 725 Note that MS COCO dataset was collected by photographing everyday objects that art was not part
 726 of, making it a valid set of negative examples of art.

727 We plot the histogram of cosine similarity of the embeddings of art and non-art images to the text
 728 embedding of ‘*an artwork*’ (see Figures 8a and 8b). We observe that the art and non-art images both
 729 the artist groups are well separated (although not perfect, Figure 9 and Figure 10 shows examples
 730 of misclassified and correctly classified images from both datasets). We choose the threshold that
 731 maximizes the F1 score of the separation (0.182 for the classical artists and 0.177 for the modern
 732 artists).

733 **Filtering Images of Other Art Styles:** Similar to the case of human faces, not all art images whose
 734 captions mention an artist were created by that artist. We want to filter out such images. For this
 735 purpose, we collect reference images for each artist (see Appendix E for details) and use them to
 736 classify the training images that belong to the artist of interest. Concretely, we measure the similarity
 737 between the pretraining images and the reference images of each artist, and only retain images whose
 738 similarity to the reference images is higher than a threshold.

739 To determine this threshold, we measure the similarity between pairs of art images of the same artists
 740 and pairs of art images from different artists. We embed the images using an art style embedding
 741 model [51] and plot the histogram of similarities between art images of the same artist (blue colored)

(a) Images from the MS COCO dataset that were classified as art by the threshold we choose. These images clearly have paintings in them and therefore are classified in that category. These images were selected in MS COCO for different categories like scissors, chair, parking meter, and vase.

(b) Images from the Wikiarts dataset that were classified as non-art by the threshold we choose.

Figure 9: Images that are misclassified by our art vs. non-art threshold in Figure 8a.

(a) Images from the MS COCO dataset that were correctly classified as non-art.

(b) Images from the Wikiarts dataset that were correctly classified as art.

Figure 10: Images that are correctly classified by our art vs. non-art threshold in Figure 8a.

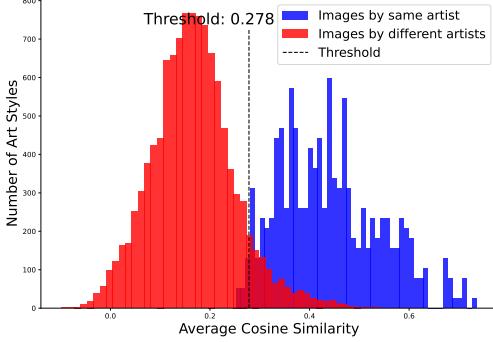

742 and art images of different artists (red colored) in Figure 11a for classical artists and Figure 11b for
 743 modern artists. We see that the two histograms are well separated (although not perfect, Figure 12
 744 shows paintings by two artists whose art style is very similar and cannot be distinguished by our
 745 threshold). We choose the threshold that maximizes the F1 score of the separation between these two
 746 groups (0.278 for classical artists and 0.288 for modern artists). The retained images give us both
 747 the image counts of each artist and the training images that we compare to the generated images to
 748 measure the imitation score.

749 G.2 Similarity Measurement

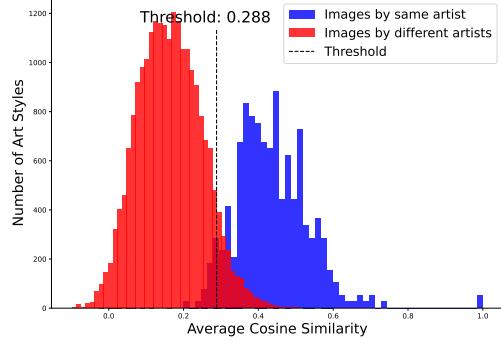

750 We embed all the generated images and the filtered pretraining images using the art style embedding
 751 model [51] and measure the cosine similarity between each pair of generated and pretraining images.
 752 Similar to the case of the human faces, we do not want to underestimate the art style similarity
 753 between the generated and training images by comparing the generated images to all the training
 754 images of this artist. Therefore, we measure the similarity of generated images to the ten training
 755 images that are on average the most similar to the generated images.

756 H Imitation Thresholds of SD models in Series 1 and 2

757 Our experimental results in Section 6 found that for most domains the imitation thresholds for SD1.1
 758 and SD1.5 are almost the same, while being higher for SD2.1. We hypothesized that the difference is
 759 due to their different text encoders. All models in SD1 series use the same text encoder from CLIP,
 760 whereas SD2.1 uses the text encoder from OpenCLIP. To test the validity of this hypothesis, we
 761 repeated the experiments for all models in SD1 series for politicians and computed their imitation
 762 thresholds. Table 5 shows the thresholds for the politicians. We find that the imitation thresholds for
 763 all the models in SD1 series is almost the same, and is lower than the threshold for SD2.1 model.
 764 This evidence supports our hypothesis of the difference in the text-encoders being the main reason
 765 for the difference in the imitation thresholds.

(a) Histogram of the average cosine similarity between embeddings of the images of the same artist (blue) and the art of different artists (red) for classical artists

(b) Histogram of the average cosine similarity between embeddings of the images of the same artist (blue) and the art of different artists (red) for modern artists

Figure 11: The second filtering step involves determining the if an art work whose caption mentions an artist actually belongs to that artist or not.

(a) Paintings made by Kitagawa Utamaro.

(b) Paintings made by Tsukioka Yoshitoshi

Figure 12: Paintings made by Kitagawa Utamaro and Tsukioka Yoshitoshi are very similar and our threshold is unable to distinguish between their styles.

766 I Change Points

767 Table 6 we show all the change points that PELT found for each experiment (Table 3 reports the first
768 change point as the imitation threshold).

769 J All Results: The *Imitation Threshold*

770 In this section, we estimate the imitation threshold for human face and art style imitation for three
771 different text-to-image models. Figure 16, Figure 17, and Figure 18 show the image counts of
772 celebrities on the x-axis (sorted in increasing order of image counts) and the imitation score of their
773 generated images (averaged over the five image generation prompts) on the y-axis. The images

Table 5: *Imitation Thresholds* for politicians for all models in SD1 series and SD2.1.

Pretraining Dataset	Model	Human Faces 🧑: Politicians
LAION2B-en	SD1.1	234
	SD1.2	252
	SD1.3	234
	SD1.4	234
	SD1.5	234
LAION-5B	SD2.1	369

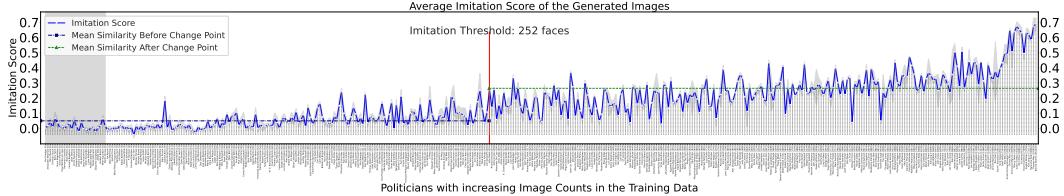

Figure 13: **Human Face Imitation (Politicians):** Similarity between the training and generated images for all politicians. The politicians with zero image counts are shaded with light gray. We show the mean and variance over the five generation prompts. The images were generated using **SD1.2**. The change point for human face imitation for politicians when generating images using SD1.1 is detected at **252 faces**.

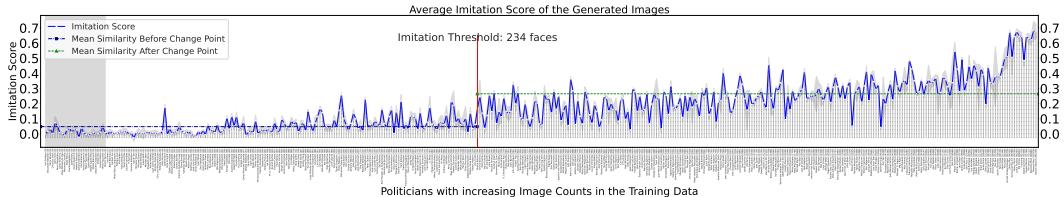

Figure 14: **Human Face Imitation (Politicians):** Similarity between the training and generated images for all politicians. The politicians with zero image counts are shaded with light gray. We show the mean and variance over the five generation prompts. The images were generated using **SD1.3**. The change point for human face imitation for politicians when generating images using SD1.1 is detected at **234 faces**.

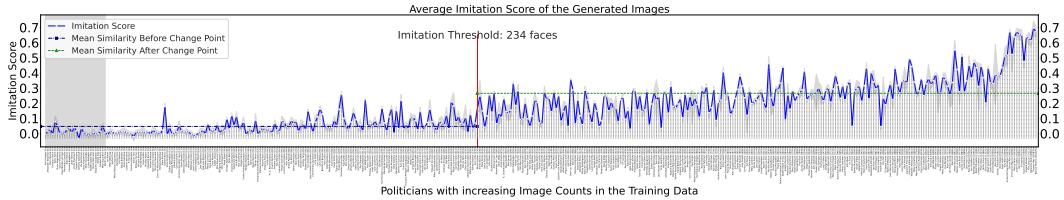

Figure 15: **Human Face Imitation (Politicians):** Similarity between the training and generated images for all politicians. The politicians with zero image counts are shaded with light gray. We show the mean and variance over the five generation prompts. The images were generated using **SD1.4**. The change point for human face imitation for politicians when generating images using SD1.1 is detected at **234 faces**.

774 were generated using SD1.1, SD1.5, and SD2.1 respectively. Similarity, Figure 19, Figure 20, and
 775 Figure 21 shows the image counts of the politicians and the imitation score of their generated images,
 776 for SD1.1, SD1.5, and SD2.1 respectively.

777 Figure 22, Figure 23, Figure 24 show the image counts of classical artists and the similarity between
 778 their training and generated images; and Figure 25, Figure 26, Figure 27 show the image counts
 779 of modern artists and the similarity between their training and generated images. The images were
 780 generated using SD1.1, SD1.5, and SD2.1 respectively.

Table 6: *Imitation Thresholds* for human face and art style imitation for the different text-to-image models and datasets we experiment with.

Pretraining Dataset	Model	Human Faces 🧑		Art Style 🖼	
		Celebrities	Politicians	Classical Artists	Modern Artists
LAION2B-en	SD1.1	364	234	112, 391	198
	SD1.5	364, 8571	234, 4688	112, 360	198, 4821
LAION-5B	SD2.1	527, 9650	369, 8666	185, 848	241, 1132

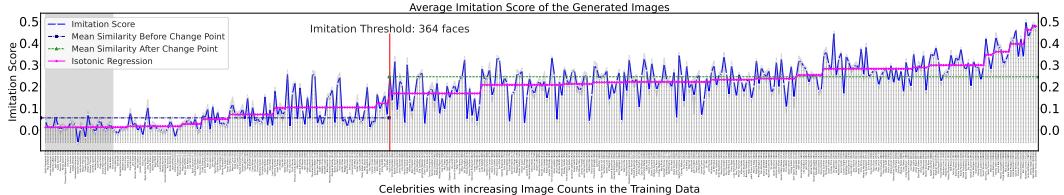

Figure 16: **Human Face Imitation (Celebrities):** Similarity between the training and generated images for all celebrities. The celebrities with zero image counts are shaded with light gray. We show the mean and variance over the five generation prompts. The images were generated using **SD1.1**. The change point for human face imitation for celebrities when generating images using SD1.1 is detected at **364 faces**.

781 **Imitation Threshold Estimation for Human Face Imitation:** In Figure 16, we observe that the
 782 imitation scores for the individuals with small image counts is close to 0 (left side), and it increases as
 783 the number of their image counts increase towards the right. The highest similarity is 0.5 and it is for
 784 the individuals in the rightmost region of the plot. The solid line in the plot shows the mean similarity
 785 over the five image generation prompt with the shaded area showing the variance over them. We
 786 observe a low variance in the imitation score among the generation prompts. And we also observe
 787 that the variance does not depend on the image counts which indicates that the performance of the
 788 face recognition model does not depend on the popularity of the individual. The change detection
 789 algorithm finds the change point to be at **364** faces for human face imitation for celebrities, when
 790 using **SD1.1** for image generation. Figure 17 shows the similarity between the training and generated
 791 images when images are generated using **SD1.5**. Identically to SD1.1, the change is detected at **364**
 792 faces for face imitation when using SD1.5. We also performed ablation experiments with different
 793 face embeddings models and justify the choice of our model (see Appendix L). For all the plots, we
 794 also analyze the trend by using isotonic regression which learns non-decreasing linear regression
 795 weights that fits the data best.

796 **Imitation Threshold Estimation for Human Face Imitation (Politicians):** Figure 19 shows the
 797 imitation scores for politicians which is very similar to the plot obtained for celebrities. We observe a
 798 low variance in the imitation score among the generation prompts. We also observe that the variance
 799 does not depend on the image counts which indicates that the performance of the face recognition
 800 model does not depend on the popularity of the individual. The change detection algorithm finds the
 801 change point to be at **234** faces for human face imitation for politicians, when using **SD1.1** for image
 802 generation. Figure 20 shows the similarity between the training and generated images when images
 803 are generated using **SD1.5**. Similar to SD1.1, the change is detected at **234** faces.

804 **Imitation Threshold Estimation for Art Style Imitation:** In Figure 22, we observe that the
 805 imitation scores for artists with low image counts have a baseline value around 0.2 (left side), and
 806 it increases as the number of their image counts increase towards the right. The highest similarity
 807 is 0.76 and it is for the artists in the rightmost region of the plot. We also observe a low variance
 808 across the generation prompts, and the variance does not depend on the image frequency of the artist.
 809 The change detection algorithm finds the change point to be at **112** images for art style imitation of
 810 classical artists, when using **SD1.1** for image generation. Figure 23 shows the similarity between the
 811 training and generated images when images are generated using **SD1.5**. Similar to SD1.1, the change
 812 is detected at **112** faces for art style imitation when using SD1.5. These thresholds are slightly higher
 813 for style imitation of modern artists, 198 for both SD1.1 and SD1.5.

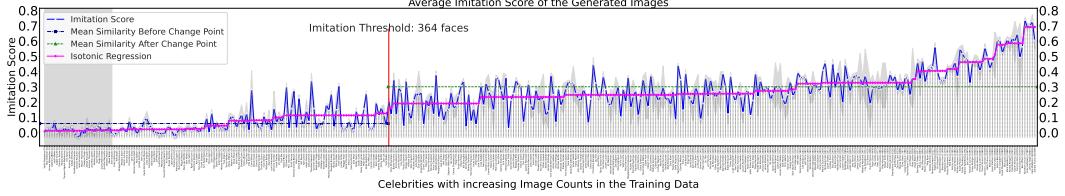

Figure 17: Human Face Imitation (Celebrities): similarity between the training and generated images for all celebrities. We show the mean and variance over the five generation prompts. The images were generated using **SD1.5**. The change point for human face imitation for celebrities when generating images using SD1.5 is detected at **364 faces**.

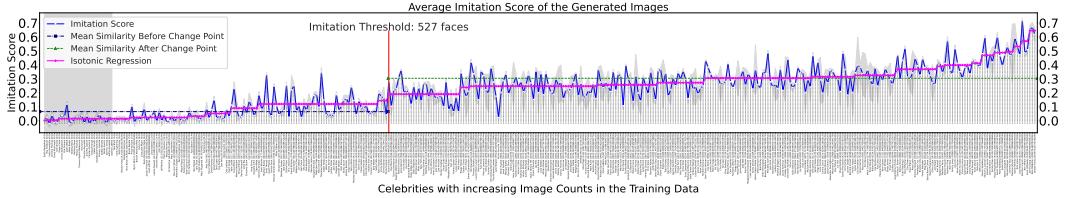

Figure 18: Human Face Imitation (Celebrities): similarity between the training and generated images for all celebrities. We show the mean and variance over the five generation prompts. The images were generated using **SD2.1**. The change point for human face imitation for celebrities when generating images using SD2.1 is detected at **527 faces**.

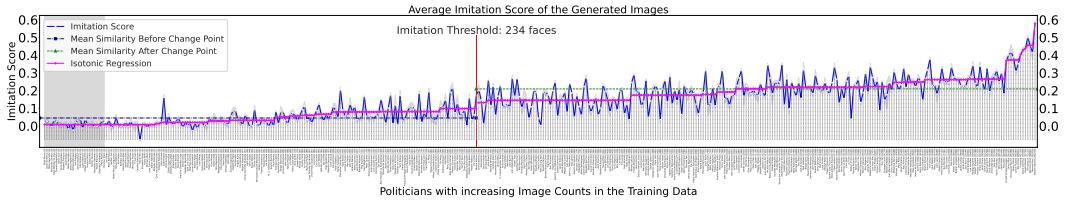

Figure 19: Human Face Imitation (Politicians): Similarity between the training and generated images for all politicians. The politicians with zero image counts are shaded with light gray. We show the mean and variance over the five generation prompts. The images were generated using **SD1.1**. The change point for human face imitation for politicians when generating images using SD1.1 is detected at **234 faces**.

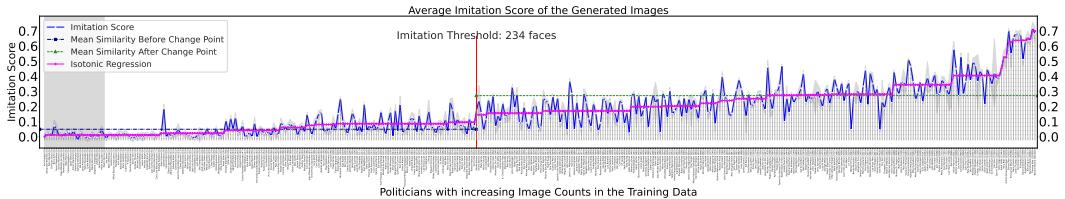

Figure 20: Human Face Imitation (Politicians): similarity between the training and generated images for all politicians. We show the mean and variance over the five generation prompts. The images were generated using **SD1.5**. The change point for human face imitation for politicians when generating images using SD1.5 is detected at **234 faces**.

814 K Examples of Outliers

815 Figure 28 and Figure 29 show examples of outliers of the first kind, where aliases of a celebrity leads
816 to under counting of their images in the pretraining data.

817 Figure 30 and Figure 31 show examples of outliers of the first kind for artists, where aliases of an
818 artist leads to under counting of their art works in the pretraining data.

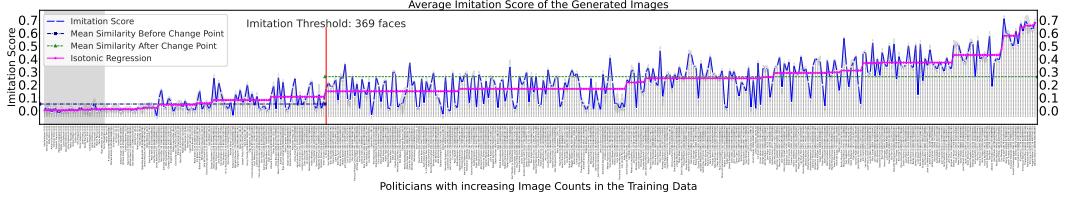

Figure 21: Human Face Imitation (Politicians): similarity between the training and generated images for all politicians. We show the mean and variance over the five generation prompts. The images were generated using **SD2.1**. The change point for human face imitation for celebrities when generating images using SD2.1 is detected at **369 faces**.

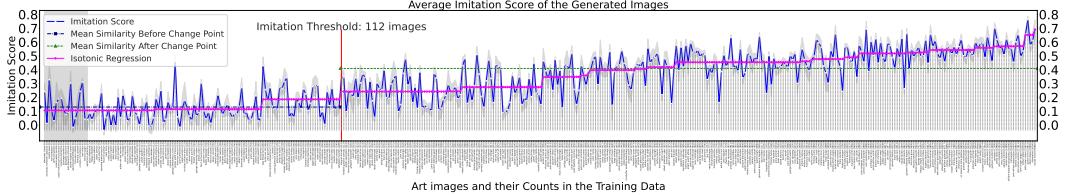

Figure 22: Art Style Imitation (Classical Artists): similarity between the training and generated images for **classical** art styles. We show the mean and variance over the five generation prompts. The images were generated using **SD1.1**. The change point for art style imitation when generating images using SD1.1 is detected at **112 images**.

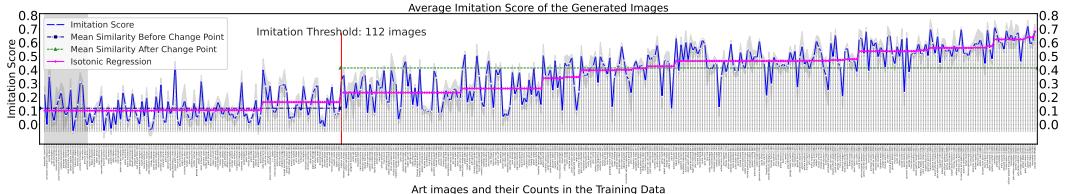

Figure 23: Art Style Imitation (Classical Artists): similarity between the training and generated images for **classical** art styles. We show the mean and variance over the five generation prompts. The images were generated using **SD1.5**. The change point for art style imitation when generating images using SD1.5 is detected at **112 images**.

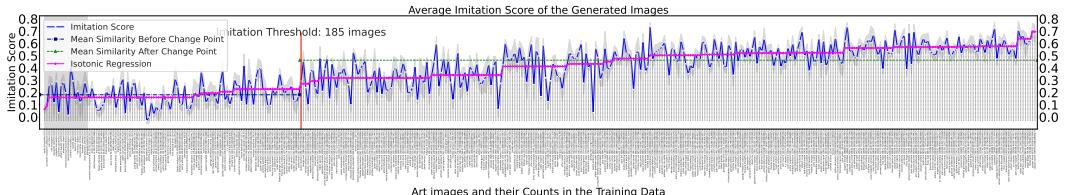

Figure 24: Art Style Imitation (Classical Artists): similarity between the training and generated images for **classical** art styles. We show the mean and variance over the five generation prompts. The images were generated using **SD2.1**. The change point for art style imitation when generating images using SD2.1 is detected at **185 images**.

819 L Ablation Experiment with Different Face Embedding Models

820 In this section, we show the difference in the performance of several face embedding models and
 821 justify the choice of the final choice of our face embedding model. Face embedding models are
 822 evaluated using two main metrics: false-match rate (FMR) and true-match rate (TMR) [31]. FMR
 823 measures how many times does a model says two people are the same when they are not and TMR
 824 measures how many times a model says two people are the same when they are the same. Ideally, a
 825 face embedding model should have low FMR and high TMR. An important variant of these metrics
 826 is the disparity of FMR and TMR of a model across different demographic groups. Ideally, a model

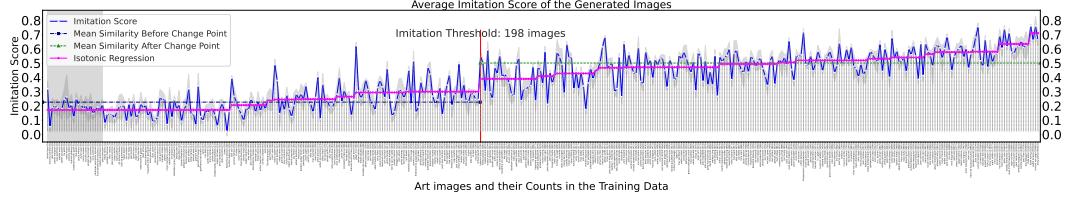

Figure 25: **Art Style Imitation (Modern Artists):** similarity between the training and generated images for **modern** art styles. We show the mean and variance over the five generation prompts. The images were generated using **SD1.1**. The change point for art style imitation when generating images using SD1.1 is detected at **198 images**.

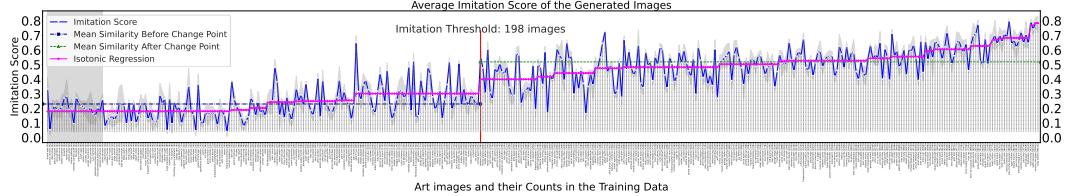

Figure 26: **Art Style Imitation (Modern Artists):** similarity between the training and generated images for **modern** art styles. We show the mean and variance over the five generation prompts. The images were generated using **SD1.5**. The change point for art style imitation when generating images using SD1.5 is detected at **198 images**.

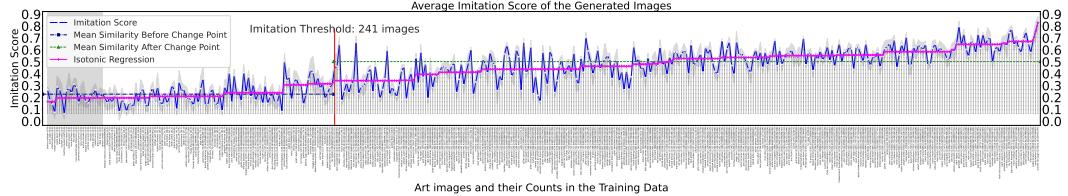

Figure 27: **Art Style Imitation (Modern Artists):** similarity between the training and generated images for **modern** art styles. We show the mean and variance over the five generation prompts. The images were generated using **SD2.1**. The change point for art style imitation when generating images using SD2.1 is detected at **241 images**.

Figure 28: **Outlier Category 1: DJ Kool Herc.** *Clive Campbell* is aliased as *DJ Kool Herc*, which leads to lower counts of his images in the dataset since MIMETIC² only collects images whose caption mentions *DJ Kool Herc*.

Figure 29: **Outlier Category 1: Summer Walker.** *Summer Marjani Walker* is aliased as *Summer Walker*, which leads to lower counts of her images in the dataset since MIMETIC² only collects images whose caption mentions *Summer Walker*.

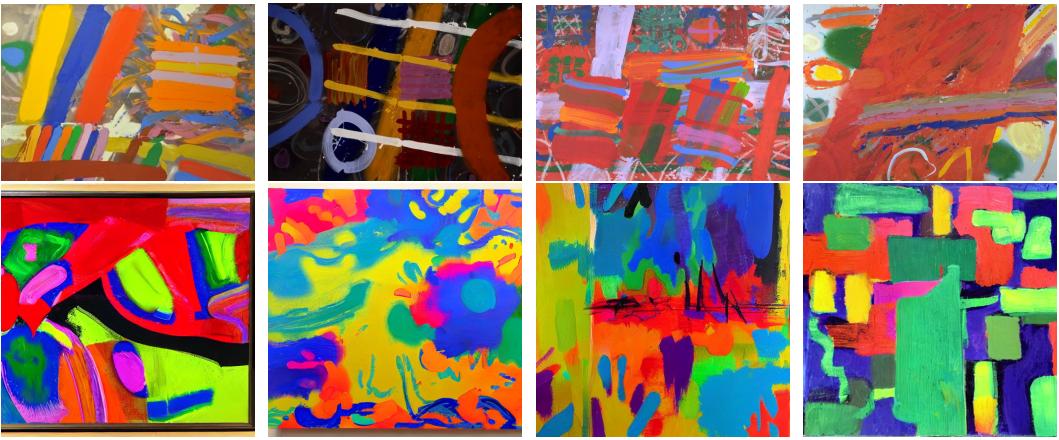

Figure 30: **Outlier Category 1: Albert Irwin.** *Albert Henry Thomas Irvin* is aliased as *Albert Irwin*, which leads to lower counts of his art images in the dataset since MIMETIC² only collects images whose caption mentions *Albert Irwin*.

827 should have low disparity in these metrics across different demographics. We also focus on the
 828 variance of these metrics across demographics in making the final choice.

829 We evaluate the FMR and TMR of eight different face embedding models (seven open-sourced
 830 and one proprietary). The open-source models were chosen based on their popularity on Github
 831 [10, 11, 45], and we also experiment with Amazon Rekognition, a proprietary model. For evaluating
 832 the disparity of these metrics across different demographic groups we grouped celebrities in six
 833 demographic groups primarily categorized according to skin color tone (black, brown, and white)
 834 and perceived gender (male and female; for simplicity). Each of the six groups had 10 celebrities (a
 835 total of 60), with no intersection between them. The categorization was done manually by looking at
 836 the reference images of the celebrities. For each celebrity, we collect 10 reference images from the
 837 internet by using the procedure described in Appendix E. We use these images to compare the FMR
 838 and TMR of the face recognition models, as these images are the gold standard images of a person.

839 **FMR Computation:** We compute the mean cosine similarity between the face embeddings of
 840 one individual and the faces of all other individuals in that group, and repeat the procedure for all
 841 individuals in a demographic group.

842 **TMR Computation:** We compute the mean cosine similarity between the embeddings of all the
 843 faces of an individual and repeat the procedure for all the individuals in a demographic group.

844 Figure 32 and Figure 33 shows the FMR and TMR for six demographic groups for all the face
 845 embedding models. All the open-sourced models, except InsightFace, either have a high disparity
 846 in FMR values across the demographic groups (ArcFace, Facenet, Facenet512, DeepFace) or have

Figure 31: **Outlier Category 1: Gustav Adolf Mossa.** *Gustav Adolf Mossa* is aliased just as *Mossa*, which leads to lower counts of his art images in the dataset since MIMETIC² only collects images whose caption mentions *Gustav Adolf Mossa*.

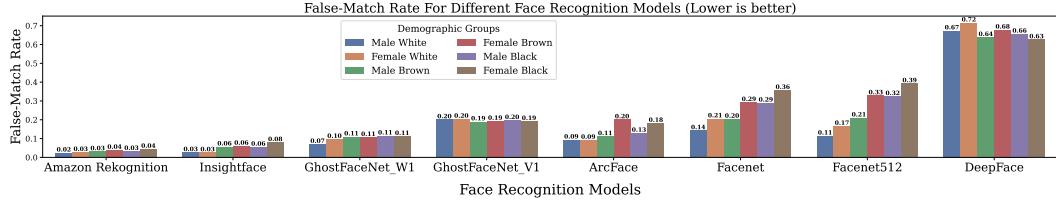

Figure 32: False-match rate (FMR) of all the face embedding models across the six demographic groups. Amazon Rekognition and InsightFace have the lowest FMR values. Moreover, these two models have lowest disparity of FMR over the demographic groups.

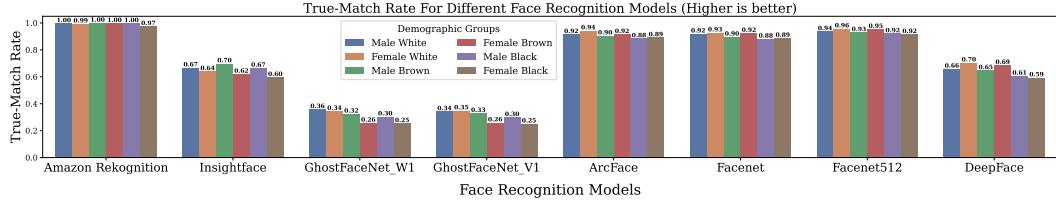

Figure 33: True-match rate (TMR) of all the face embedding models across the six demographic groups. Amazon Rekognition model has the highest TMR values.

847 very low TMR (GhostFaceNet_W1, GhostFaceNet_V1). We choose InsightFace for our experiments
848 because of it has 1) a low overall FMR, 2) decent TMR, 3) a low disparity of FMR and TMR
849 across the demographic groups, and 4) is open-sourced. Having a low disparity of the metrics across
850 individuals of different demographic groups is crucial for an accurate estimation of the imitation
851 threshold. The Amazon Rekognition model would also be a viable choice based on these metrics,
852 however, it is not open-sourced and therefore expensive for our experiments.

853 M Count Distribution and the List of Sampled Entities for Each Domain

854 M.1 Celebrities

855 We collect celebrities from <https://www.popsugar.com/Celebrities> and <https://celebabswers.com/celebrity-list/>. The distribution of the caption counts of the sampled
856 celebrities is displayed in Table 7. The sampled celebrities in the descending order of their number of
857 caption counts are:
858

Table 7: Distribution of caption counts for sampled entities in celebrities, politicians, and art styles domains.

Caption Counts (LAION-2B)	Celebrities	Politicians	Classical Artists	Modern Artists
0	19	15	14	15
1-100	48	60	67	69
100-500	57	120	133	139
500-1K	52	80	62	62
1K-5K	151	65	63	64
5K-10K	19	40	39	32
> 10K	53	40	40	34

859 Donald Trump, Kate Middleton, Abraham Lincoln, Johnny Depp, Stephen King, Anne Hathaway, Ben Affleck, Ronald Reagan, Oprah Winfrey, Floyd
 860 Mayweather, Dwayne Johnson, Cameron Diaz, Cate Blanchett, Mark Wahlberg, Naomi Campbell, Nick Jonas, Jessica Biel, Kendrick Lamar, Malcolm X,
 861 Steven Spielberg, Bella Thorne, Bob Ross, Jay Leno, David Tennant, Samuel L. Jackson, Jason Statham, Mandy Moore, Victoria Justice, Scott
 862 Diskic, Martin Scorsese, Ashley Olsen, Carey Mulligan, Greta Thunberg, Ashlee Simpson, Kacey Musgraves, Kurt Russell, Felicity Jones, Saoirse
 863 Ronan, Sarah Paulson, Matthew Perry, Forest Whitaker, Brendon Urie, Meg Ryan, Olivia Culpo, Joe Rogan, Sacha Baron Cohen, Terrence Howard,
 864 Natalie Dormer, Ansel Elgort, Nick Offerman, Clive Owen, Rose Leslie, Sterling K. Brown, Cuba Gooding Jr., Kevin James, Marisa Tomei, Troye
 865 Sivan, Zachary Levi, Gwendoline Christie, Hunter Hayes, Melanie Martinez, Joel McHale, Ross Lynch, Brody Jenner, Riley Keough, Robert Kraft,
 866 Ray Liotta, Eric Bana, Mark Consuelos, Chris Farley, Lauren Daigle, Lily Donaldson, Penélope Cruz, Karen Elson, Joey Fatone,
 867 Leslie Odom Jr., Jay Baruchel, Selita Ebanks, Lana Condor, Mackenzie Foy, Doja Cat, Skai Jackson, Sofia Hellqvist, Bernard Arnault, Josh Peck,
 868 Lindsay Price, Phoebe Bridgers, Sarah Chalke, Alexander Skarsgård, Tai Lopez, Léa Seydoux, Cam Gigandet, David Dobrik, Jacob Elordi, Omar Epps,
 869 Marsala Martin, Alyson Stoner, Dree Hemingway, Gregg Sulkin, Mamie Gummer, Allison Holker, Chris Watts, Jacob Sartorius, Christine Quinn, Torrey
 870 Devitto, Alek Wek, Sandra Cisneros, Robert Irvine, Danielle Fishel, Norman Kordei, Sam Taylor Johnson, Jessica Seinfeld, Rachelle Lefevre,
 871 Joyner Lucas, Jimmy Buffet, John Wayne Gacy, Marvin Sapp, Ryan Guzman, Lindsay Ellingson, John Corbett, Michaela Coel, Hanne Gaby Odiele,
 872 Christiano Ronaldo, Scott Speedman, Addison Rae, Justice Smith, Stella Tenant, Lindsay Wagner, AJ Michalka, Charles Melton, Patricia Field,
 873 Dan Bilzerian, Anya Murphy, Michael Huisman, Sara Foster, Diego Boneta, Danny Thomas, Oliver Hudson, Lauren Bushnell, Chris Klein, Rodrigo
 874 Santoro, Luke Hemsworth, Rhea Perlman, Michael Pena, Jodie Turner-Smith, Trevor Jackson, Jenna Marbles, Bob Morley, Zak Bagans, Liza Koshy,
 875 Steve Lacy, Nico Tortorella, Emma Corrin, Lo Bosworth, Quvenzhané Wallis, Martin Starr, David Muir, Beanie Feldstein, Lori Harvey, Eddie
 876 McGuire, Todd Chrisley, Dan Crenshaw, Amanda Gorman, Crystal Renn, Mark Richt, Magdalena Frackowiak, Danielle Jonas, Liu Yifei, Sasha
 877 Pivovarova, Ashleigh Murray, Peter Hermann, Daria Strokous, Eddie Hall, Hunter Parrish, Matt McGorry, Diane Guerrero, Simi Liu, Brady Quinn,
 878 Jill Wagner, Richard Rawlings, Sophia Lillis, Genesis Rodriguez, Diana Ladd, Franklin Richardson, Olivia Rodrigo, Anwar Hadid, Hannah Bronfman,
 879 Deana Carter, Tia Okamoto, Fei Fei Sun, Taylor Tomasi Hill, Jared Followill, Margherita Missoni, Elisa Sednaoui, Thomas Doherty, Bill
 880 Skarsgård, Indya Moore, Ziyi Zhang, Cacee Cobb, Jay Ellis, Arthur Blank, Chris McCandless, Paol de la Huerta, Jacqueline Jablonski, Michael
 881 Bufer, Annie LeBlanc, Kieran Culkin, Lacey Evans, Rachel Antonoff, Presley Gerber, Lauren Bush Lauren, Peter Firth, Tina Knowles-Lawson,
 882 Sunisa Lee, Douglas Brinkley, Hero Fiennes-Tiffin, Erin Foster, Justina Machado, Mariacarla Boscono, Summer Walker, Emma Chamberlain, Lew
 883 Alcindor, Jenna Ortega, Phoebe Dynevor, Kim Zolciak-Biermann, Allison Stokke, Malgosia Bela, Isabel Toledo, Sydney Sweeney, Mat Fraser, Hunter
 884 McGrady, Ethan Suplee, Tammy Hembrow, Ivan Moody, Danneel Harris, Marcus Lemonis, Hunter Schafer, Luke Sabbat, Sam Elliott, Kendra Spears,
 885 Stephen Witch Boss, Joe Lacob, Tommy Dorfman, Emma Barton, Elliot Page, Sh'a'Carri Richardson, Barry Weiss, Julie Chrisley, Devon Sawa, Miles
 886 Heizer, Julia Stegner, Austin Abrams, Jacquette Wheeler, Melania Iglesias, Anna Cleveland, Eliza González, Grant Achatz, Mata Stonie, Connor

 893 Alcindor, Isasia Presley, Thandie Newton, Nicolo Fosse, Shenan Grimes-Beech, Alex Choi, Scott Yancey, Ciara Wilson, Lexi Underwood, Manny
 894 Khoshbin, Elle Emhoff, Cole LaBrant, Wayne Carini, Greg Fisher, Ryan Upchurch, Marcus Freeman, Danielle Cohn, Sue Aikens, Kyle Cooke, David
 895 Portnoy, Avani Gregg, Dan Peña, Quinton Reynolds, Eric Porterfield, Ayo Edebiri, Tara Lynn Wilson, Florence Hunt, Nicola Porcella, Pashmina
 896 Roshan, Josh Seiter, Ben Mallah, Miguel Bezos, Lukita Maxwell, Ali Skovbye, Jordan Firstman, Jeff Molina, Mary Lee Pfeiffer, Cody Lightning,
 897 Leah Jeffries, Elle Graham, Hannah Margaret Selleck, Woody Norman, Tora Blyth, Banks Repeta, Wisdom Page, Kris Tyson, Joey Klaasen, Tioreore
 898 Ngatai-Melbourne, Jani Zhao, Cara Jade Myers, Keyla Monterroso Mejia, Samara Joy, Mason Thames, Park Ji-hu, Boman Martinez-Reid, Priya Kansara,
 899 Yasmin Finney, Bridgette Doremus, Aria Mia Loberti, Isabel Gravitt, Gabriel LaBelle, Delaney Rose, Armen Nahapetian, Aditya Kusupati, Vedang
 900 Raina, Arsema Thomas, Adwa Bader, Amaury Lorenzo, Corey Mylchreest, Sam Nivola, Gabby Windey, Cwaayal Singh, Jaylin Webb, Kudakwashe Rutendo,
 901 Chintan Rachchh, Sajith Rajapaksa, Diego Calva, Pardis Saremi, Dominic Sessa, India Amarteifio, Mia Challiner, Aryan Simhadri

902 M.2 Politicians

903 We collect politicians from Wikipedia [58]. The distribution of the caption counts of the sampled
 904 politicians is given in Table 7. The sampled politicians in the descending order of their number of
 905 caption counts are:

906 Barack Obama, John Lewis, Theresa May, Narendra Modi, Kim Jong-un, David Cameron, Angela Merkel, Bill Clinton, Xi Jinping, Justin Trudeau, Emmanuel
 907 Macron, Nancy Pelosi, Arnold Schwarzenegger, Ron Paul, Shinzo Abe, Adolf Hitler, John Paul II, Tony Blair, Sachin Tendulkar, Nick Clegg, Newt
 908 Gingrich, Scott Morrison, Arvind Kejriwal, Ilham Aliyev, Jacob Zuma, Bashar al-Assad, Laura Bush, Sonia Gandhi, Kim Jong-il, Robert Mugabe,
 909 James Comey, Rodrigo Duterte, Pete Buttigieg, Lindsey Graham, Hosni Mubarak, Enda Kenny, Alexei Navalny, Rob Ford, Lee Varadkar, Evo Morales,
 910 Lee Hsien Loong, Henry Kissinger, Petro Poroshenko, Joko Widodo, Clarence Thomas, Rishi Sunak, Mohamed Morsi, Ashra Ghani, Martin McGuinness,
 911 Viktor Orban, Uhuru Kenyatta, Mike Huckabee, Sheikh Hasina, Martin Schulz, Giuseppe Conte, John Howard, Benito Mussolini, Tulsi Gabbard,
 912 Dominic Raab, Michael D. Higgins, François Hollandé, Yasser Arafat, Mark Rutte, Mahathir Mohamad, Juan Manuel Santos, Abiy Ahmed, William
 913 Prince, Lee Kuang Yew, Mikhail Gorbachev, Hun Sen, Jacques Chirac, Martin O'Malley, Benazir Bhutto, Yoshihiko Suga, John Major, Muamar Gaddafi,
 914 Jerry Springer, Sandra Day O'Connor, Madeleine Albright, Thomas Mann, Paul Kagame, Simon Coveney, Grant Shapps, Sebastian Coe, Merrick Garland,
 915 Jean-Yves Le Drian, Nursultan Nazarbayev, Horst Seehofer, Liz Truss, Rovani Williams, Ellen Johnson Sirleaf, George Weah, Mark Sanford, Yoweri
 916 Museveni, Luigi Di Maio, Ben Wallace, Herman Van Rompuy, Daniel Ortega, Olaf Scholz, Beppe Grillo, Alassane Ouattara, Nicolás Maduro, Tamim bin
 917 Hamad Al Thani, Mary McAleese, Asif Ali Zardari, Joseph Goebbels, Nikol Pashinyan, Deb Haaland, Paul Biya, Alfred Fattah el-Sisi, Thabo Mbeki,
 918 Kyriakos Mitsotakis, Joseph Muscat, Micheál Martin, Rebecca Long-Bailey, Paschal Donohoe, Todd Young, Jean-Marie Le Pen, Nick Griffin, Zoran
 919 Zaev, Pierre Nkurunziza, Abhisit Vejjajiva, Maggie Hassan, Steven Chu, Juan Guaidó, Edi Rama, Mary Landrieu, Jyrki Katainen, Jene Spahn, John
 920 Dramani Mahama, Gina Raimondo, Alec Douglas-Home, Viktor Orbán, Anita Anand, Isaias Afwerki, James Cleverly, Ibrahim Mohamed Solih, Leymah
 921 Gbowee, Vaclav Havel, John Rawls, Jack McConnell, Romano Prodi, Eoghan Murphy, Vicki Leandros, Norodom Sihamoni, Nayib Bukele, Shirin Ebadi,
 922 Jusuf Kalla, George Eustice, Joachim von Ribbentrop, Peter Altmaier, Akbar Hashemi Rafsanjani, Paul Singer, Christian Stock, Moussa Faki,
 923 Dominique de Villepin, Michael Fabricant, Kim Dae-jung, Eamon Ryan, Shakhat Mirziyoyev, Denis Sassou-Nguesso, Werner Faymann, Kamla
 924 Persaud-Bissessar, Ingrid Betancourt, Volodymyr Zelensky, Park Chung Hee, Elvira Nabuñilina, Roselyne Bachelot, Heinrich Fischer, Hideki Tojo,
 925 Anatoly Karpov, Marcelo Ebrard, Slavoj Žížek, Trent Lott, Carl Bildt, Almazbek Atambayev, Andry Rajoelina, Carl Schmitt, Ralph Gonsalves, Liam Byrne,
 926 Castillo, Winona LaDuke, Peter Bell, Boyko Borisov, Carl Bildt, Almazbek Atambayev, Andry Rajoelina, Carl Schmitt, Ralph Gonsalves, Liam Byrne,
 927 Alok Sharma, Jean-Michel Blanquer, Robert Schuman, Shinzō Abe, Doris Leuthard, Jacques Delors, Floella Benjamin, Sauli Niinistö, Annalena
 928 Baerbock, Toomas Hendrik Ilves, Alejandro Giammattei, Bob Kerrey, Lionel Jospin, Murray McCully, Stefan Löfven, Javier Solana, Salva Kiir
 929 Maynard, Cecil Williams, Shahbaz Bhatti, Marianne Thyssen, Marty Natalegawa, Roh Moo-hyun, John Diefenbaker, Antonio Inoki, Iván Duque, CY
 930 Leung, Tom Tancredo, Sigrid Kaag, Jim Bolger, Lou Barletta, Li Peng, Laura Chinchilla, Gennady Zyuganov, Chen Shui-bian,
 931 Sebastián Piñera, Gustavo Petro, Miguel Diaz-Canel, Alberto Fernández, Gerald Darmanin, Boutros Boutros-Ghali, Joschka Fischer, Maia Sandu, Ricardo
 932 Martínez, Andrej Babšač, Dan Jarvis, Nikos Dendias, Chris Hipkins, Tawakkol Karman, Booth Gardner, Karin Kneissl, Mobutu Sese Seko, Alexander
 933 Haig, Alexander De Croo, Ahmed Aboul Gheit, Yasuo Fukuda, Jean-Luc Mélenchon, Jane Ellison, Diana Dodds, Helen Whately, Idriss Déby, Patrice
 934 Talon, Carmen Calvo, Dario Franceschini, Emma Bonino, Richard Ferrand, Andreas Scheuer, Moshe Katsav, K. Chandrashekhar Rao, P. Harrison, Robert

954 M.3 Classical Artists

955 We collected classical artists from the <https://www.wikiart.org>, a website that collects various arts
 956 from different artists and categorizes them into pre-defined art style categories. For classical artists,
 957 we collected the artist names from the art styles: *Romanticism, Impressionism, Realism, Baroque,*
 958 *Neoclassicism, Rococo, Academic Art, Symbolism, Cubism, Naturalism*. The distribution of the
 959 caption counts of the sampled artists is given in Table 7. The sampled artists in the descending order
 960 of their number of caption counts are:

961 → Claude Monet, Rembrandt, Gustav Klimt, Edgar Degas, Caravaggio, William Blake, John James Audubon, Le Corbusier, Canaletto, Peter Paul Rubens,
 962 → John Singer Sargent, Edouard Manet, John William Waterhouse, Alfred Sisley, Childe Hassam, Berthe Morisot, Victor Hugo, William-Adolphe
 963 → Bouguereau, Gustave Courbet, Albert Bierstadt, Mary Cassatt, John Constable, Gustave Doré, Gustave Caillebotte, Henry Moore, Thomas Hardy,
 964 → Johannes Vermeer, Jacques-Louis David, Odilon Redon, Thomas Cole, Thomas Moran, James Tissot, William Hogarth, David Roberts, Thomas
 965 → Gainsborough, Anthony Van Dyck, William Merritt Chase, Caspar David Friedrich, Sir Lawrence Alma-Tadema, George Stubbs, Georges Braque, Auguste
 966 → Rodin, Joshua Reynolds, John Atkinson Grimshaw, David James, James Ward, David Johnson, Frederic Edwin Church, Jean-Léon Gérôme, Eugène
 967 → Delacroix, Martin Johnson Heade, Edward Burne-Jones, John William Godward, James McNeill Whistler, Ilya Repin, William Bradford, Julia Margaret Cameron, Annibale
 968 → Francisco Goya, John Everett Millais, Thomas Lawrence, John Ruskin, John Russell, David Davies, Dante Gabriel Rossetti, George Henry, John
 969 → Martin, Frans Hals, Guido Reni, George Catlin, Claude Lorrain, Anders Zorn, Jessie Willcox Smith, Giovanni Battista Tiepolo, Howard Pyle,
 970 → Archibald Thorburn, Thomas Eakins, Giovanni Boldini, Armand Guillaumin, Ivan Aivazovsky, John Trumbull, Joseph Wright, Benjamin West, John
 971 → Collier, Henri Fantin-Latour, Jan Steen, Eugene Boudin, James McNeill Whistler, Ilya Repin, William Bradford, Julia Margaret Cameron, Annibale
 972 → Carracci, Antoine Watteau, Marianne North,
 973 → David Cox, Jacob Jordáens, Frederick Morgan, Ivan Shishkin, George Morland, Ford Madox Brown, Frans Snyders, John Jackson, Aelbert Cuyp,
 974 → Charles Willson Peale, Jacob Van Ruisdael, Joseph Dureux, Horace Vernet, Pieter De Hooch, Arthur Hughes, Antonio Canova, Charles Le Brun,
 975 → Francesco Hayez, Thomas Sulky, Isaac Levitan, Robert Spencer, Karl Bodmer, Alexandre Cabanel, N.C. Wyeth, Anna Ancher, Carl Spitzweg, David
 976 → Wilkie, Paul Delaroche, Charles-François Daubigny, George Frederick Watts, Guy Rose, Carel Fabritius, Alfred Stevens, Peder Severin Kroyer,
 977 → Taras Shevchenko, Pietro Longhi, Joaquín Sorolla, Theodore Chasserier, John Riley, Theodore Rousseau, Edmund Charles Tarbell, Giovanni Domenico
 978 → Tiepolo, Edward Ladell, Pompeo Batoni, Richard Parkes Bonington, Boris Kustodiev, Andreas Achenga, Charles Conder, Viktor Vasnetsov, Antoine
 979 → Blanchard, William Henry Hunt, Emile Claus, Julian Alden Weir, Mikhail Vrubel, Richard Dadd, Vasily Vereshchagin, John Hopner, Richard
 980 → Lindner, Aristide Maillol, Joan Blaue, William Williams, Adriaen Brouwer, Constant Troyon, Fernand Khnopff, Edwin Austin Abbey, Gino Severini,
 981 → Pietro Da Cortona, Adriæn Van De Velde, Vasily Perov, David Bomberg, Konstantin Korovin, Christoffer Wilhelm Eckersberg, Jean Mitzner,
 982 → Konstantin Makovsky, Mihaly Munkacsy, Albert Pinkham Ryder, Francesco Solimena, Franz Richard Unterberger, Roger De La Fresnaye, William
 983 → Shayer, Paul Brill, Cornelis Springer, Jacques Lipchitz, Agostino Carracci, Adam Elsheimer, Giuseppe De Nittis, Jules Joseph Lefebvre, Albert
 984 → Gleizes, Willard Metcalf, Vasily Surikov, Giovanni Fattori, Lyubov Popova, Kuzma Petrov-Vodkin, Johan Christian Dahl, Jehan Georges Vibert,
 985 → Mikhail Nesterov, Antoine Pesne, Konstantin Yuon, Hugo Simberg, Gerard Terborch, Alexander Ivanov, Eustache Le Sueur, Giuseppe Maria Crespi,
 986 → Ferdinand Bol, Max Slevogt, Philip Wilson Steer, Osias Beert, Vasily Polenov, John Crome, Edward Poynter, Nicolae Grigorescu, Louis Marcoussis,
 987 → Marcus Stone, Jacques Stella, Edmonia Lewis, Antonietta Brandeis, Konstantin Somov, Hendrick Terbrugghen, Cornelis De Vos, Charles Spencelayh,
 988 → Ivan Kramskoy, Rudolf Von Alt, Philippe Otto Runge, Carolus-Duran, Ralph Earl, Eugène Carrière, Julius Leblanc Stewart, Ippolito Caffi, John
 989 → Peter Russell, Jean Baptiste Vannier, Antonio Mancini, Petrus Van Schendel, Benjamin Brown, Max Klinger, Ludwig Knaus, Maurice Braun, Vincenzo
 990 → Camuccini, Jean-Étienne Liottard, Henry Tonks, Jacek Malczewski, Rubens Santoro, Pieter Codde, Jean-Paul Laurens, Louise Moillon, Jan
 991 → Siberechts, David Morier, John Pettie, Felicien Rops, Leon Bonnat, Théodore Ribot, William Logsdail, Richard Jack, Homer Watson, François
 992 → Gérard, Robert Julian Onderdonk, Lionel Noel Royer, Charles Gleyre, Anne Brigman, Thomas Jones Barker, Antonio Ciseri, Joseph Anton Koch, Anton
 993 → Melbye, Nicolas Tournier, Peter Nicolai Arbo, Lev Lagorio, Matthias Stom, Jean-Baptiste Van Loo, Konstantinos Volanakis, Cornelis Vreedenburgh,
 994 → Henry Siemiradzki, Frederick George Cotman, Eva Gonzales, Jan Cossiers, Julio González, Vladimír Makovský, Fyodor Bronnikov, Paul Peel, Thomas
 995 → Pollock Anshutz, Raden Saleh, Robert Lewis Reid, Joseph-Marie Vien, Arne Breker, Frederick William Burton, Ion Andreescu, Janek Adler, William
 996 → Leighton Leitch, Esaias Van De Velde, Dirk Van Baburen, Jacob Van Strij, Frans Stuck, Giovanni Battista Gaulli, Hans Gude, Harriet Backer,
 997 → Nicolas Antoine Taunay, Fyodor Alekseyev, Vasily Tropinin, Alfred Dehodencq, Alexey Venetianov, Francisca Davis Millet, Laszlo Mednyanszky,
 998 → Charles Hermans, Christina Robertson, Thomas Francis Dicksee, Fyodor Vasilyev, Claudio Coello, Gustave Boulanger, Nikolaos Gyzis, George Ault,
 999 → Francisco Herrera, John Lewis Krimmel, Marie Bashkirtseff, Sébastien Bourdon, Jacob Ochtervelt, Christen Kobke, Paul Gavarni, Eduard
 1000 → Debat-Ponsan, Gregoire Boonzaier, Dmitry Levitzky, André Gill, Julian Ashton, Telemaco Signorini, Orest Kiprensky, Fyodor Rokotov, Nicolas
 1001 → Toussaint Charlet, Pieter Saenredam, Henri-Pierre Picou, Johan Hendrik Weissenbruch, Émile Friant, Herbert Gustave Schmalz, Jean-Baptiste
 1002 → Pigalle, T. C. Steele, Arturo Michelena, Wilhelm Von Kaulbach, Alfonso Tormalje, Giovanni Costa, Paul Leroy, Ivan Vladimirov, Hermann Hendrich,
 1003 → Magnus Enckell, Pavel Fedotov, Ethel Carrick, Vincenzo Irolli, Leopold Survage, Lady Frieda Harris, Joseph Duplessis, Charles Maurin, Philip De
 1004 → László, Peter Fendi, Marie-Guillemine Benoist, Antonia Paoletti, Christian Wilhelm Allers, Tranquillo Cremona, Antonio Donghi, Henry Williams,
 1005 → Miklós Barabás, Alfred Concanan, Albert Maignan, Dobré Dobrev, Bertalan Székely, Mariano Morellse, Anton Azbe, Johannes Morellse, Niclae
 1006 → Vermont, Heinrich Bürkel, Jane Sutherland, Laslett John Pott, Petro Khodolny, Alexey Zubov, Eliseo Visconti, Pieter Wenning, Henri Le
 1007 → Faconnier, Paul Ackerman, Armand Henrion, Ipolit Strambu, George Hemming Mason, Vilhelms Purvitis, Mykola Yaroshenko, Pavel Svintin, Gustav
 1008 → Adolfo Mossa, Fyodor Solntsev, Pedro Américo, Klavdy Lebedev, Ivan Milev, Albert Benois, Alexandre Antigna, George Demetrescu Mirea, Giulia
 1009 → Lama, Aurelio Tiratelli, Konstantin Vasiliev, Domenico Fiasella, David Kakabadze, Cornelis Van Noorde, Panos Terlemezian, Alexei Korzukhin,
 1010 → Maurice Poirson, Joaquin Agrasot, Toby Edward Rosenthal, Heinrich Papin, Vasile Popescu, Jérôme-Martin Langlois, Karl Edvard Diriks, Adam Van
 1011 → Der Meulen, Vsevolod Makovsky, Leo Leuppi, Matej Sternen, Filippo Cifariello, Apollinary Goravsky, Pasquale Celomni, Giuseppe Barberis,
 1012 → Francesco Didionis, Octav Angelhela, Vytautas Kairiukstis, Gevorg Bashindzhagian, Serhij Schyschko, Noé Bordignon, Armando Montaner Valdueza,
 1013 → Alexander Clarot, Rosario Weiss Zorrilla, Vasyl Hryhorivych Krychevsky, Fernand Combes, Francesco Ribalta, Jean Alexandru Steriadi, Johann
 1014 → Baptist Clarot, Corneliu Michaelescu, Nzante Spee

1015 M.4 Modern Artists

1016 We also collected modern artists from the <https://www.wikiart.org>. For modern artists, we collected
 1017 the artist names from the art styles: *Expressionism, Surrealism, Abstract Expressionism, Pop Art,*
 1018 *Art Informel, Post-Painterly Abstraction, Neo-Expressionism, Post-Minimalism, Neo-Impressionism,*
 1019 *Neo-Romanticism, Post-Impressionism*. The distribution of the caption counts of the sampled artists
 1020 is given in Table 7. The sampled artists in the descending order of their number of caption counts are:

1021 Vincent Van Gogh, David Bowie, Andy Warhol, Pablo Picasso, Frida Kahlo, Keith Haring, Salvador Dali, Paul Gauguin, Camille Pissarro, Paul
 1022 Cezanne, Henri Matisse, Paul Klee, Francis Bacon, Edward Munch, Amadeo Modigliani, Egon Schiele, Jean-Michel Basquiat, David Lynch, Wassily
 1023 Kandinsky, Peter Max, Roy Lichtenstein, Paul Reed, Franco Marc, David Smith, Mark Rothko, Georges Seurat, Leroy Neiman, Joan Miró, Jackson
 1024 Pollock, August Macke, Max Ray, Pier Mondrian, Cy Twombly, Henri De Toulouse-Lautrec, Graham Bell, Paul Signac, Robert Indiana, Yayoi Kusama,
 1025 Rene Magritte, Jasper Johns, Walter Crane, Robert Morris, Emily Carr, Lucian Freud, Ernst Ludwig Kirchner, Tom Thomson, Anish Kapoor, Alex
 1026 Katz, Pierre Bonnard, John Cage, Jim Dine, Ellsworth Kelly, Peter Blake, William Scott, Erin Hanson, Marcel Duchamp, Frank Stella, Robert
 1027 Motherwell, Max Weber, Louise Nevelson, Peter Phillips, Willem De Kooning, Corneille, Wayne Thiebaud, Joan Mitchell, Jean Cocteau, Raoul Dufy,
 1028 Antony Gormley, Max Ernst, Alberto Giacometti, Vanessa Bell, Richard Diebenkorn, James Rosenquist, Edouard Vuillard, Richard Hamilton, M.C.
 1029 Escher, Sam Francis, Sean Scully, Anselm Kiefer, Edward Weston, Karel Appel, Philip Guston, Julian Schnabel, Ray Parker, James Ensor, Balthus,
 1030 George Segal, Francis Picabia, Emil Nolde, Georges Rouault, Alice Neel, Helen Frankenthaler, Claes Oldenburg, Theo van Rysselberghe, Maya Lin,
 1031 Maurice Utrillo, Eric Fischl, H.R. Giger, Maurice Denis, Friedensreich Hundertwasser, Will Barnet, Paula Modersohn-Becker, Suzanne Valadon,
 1032 Bruce Nauman, El Anatsui, Lee Krasner, Joseph Cornell, Patrick Heron, James Brooks, Paula Rego, Paul Jenkins, Jules Pascin, Lyonel Feininger,
 1033 Edward Ruscha, Norman Lewis, Barnett Newman, David Park, Marie Laurencin, Rufino Tamayo, Chris Ofili, Lynd Ward, Jean-Paul Riopelle, Roger Fry,
 1034 Remedios Varo, Maxime Maufra, Paul Serusier, Jacob Epstein, Richard Deacon, Walter Sickert, Mark Tobey, Jan Toorop, Jacek Yerka, Red Grooms, Ad
 1035 Reinhardt, Eva Hesse, Oskar Kokoschka, Michael Sowa, Jean David, Sam Gilliam, Phyllida Barlow, Howard Finster, Augustus John, Elaine De
 1036 Kooning, Beauford Delaney, David Hammons, Erich Heckel, Amrita Sher-Gil, Arthur Lismer, Monica Hatoum, Etel Adnan, Brion Gysin, John Chamberlain,
 1037 Corita Kent, Allen Jones, Asger Jorn, Martin Kippenberger, George Tooker, Desmond Morris, Wolf Kahn, Jay Defeo, Irma Stern, Walasse Ting, Emile
 1038 Bernard, Katharina Fritsch, Franz Boening, John Heartfield, Auguste Herbin, Frances Hodgkins, Meret Oppenheim, Andre Masson, Karl
 1039 Schmidt-Rottluff, Hans Bellmer, Marino Marini, Morris Louis, Pyotr Konchalovsky, Richard Artschwager, Louis Cane, Betty Parsons, Max Pechstein,
 1040 Richard Pousette-Dart, Georges Lemmen, Cuno Amiet, Louis Valtat, Kit Williams, Grace Cossington Smith, John Hoyland, Dennis Oppenheim, Lynda
 1041 Benglis, James Lee Byars, Boris Grigoriev, Lili Elbe, Victor Brauner, Adrian Ghenie, Gillian Ayres, Ossip Zadkine, Alice Baily, Felix
 1042 Gonzalez-Torres, Johannes Itten, Charles Long, John Marin, Winifred Nicholson, Alfred Kubin, Charles Angrand, Zinaida Serebriakova, John Duncan
 1043 Fergusson, Norman Blum,
 1044 Harald Sohlberg, Zdzislaw Beksiński, Barkley L. Hendricks, Bruno Schulz, Toyen, Pierre Alechinsky, Hippolyte Petitjean, Nicolas De Staél,
 1045 Rainier Fetting, Hiro Yamagata, Lorser Feitelson, Taro Yamamoto, Kazuo Shiraga, Alberto Burri, Anna Trippi, Józef Rippl-Rónai, Ronald Davis,
 1046 Tsuguharu Foujita, Wols, Keith Sonnier, Henry Van De Velde, Chang Dai-Chien, Stanley Whitney, Ann Hamilton, John Brack, Jules-Alexandre Grun,
 1047 Billy Apple, Eileen Agar, Benny Andrews, Moïse Kisling, Edward Wadsworth, Paul Thek, Audrey Flack, Allan D'Arcangelo, Rik Wouters, Charles
 1048 Cottet, Gene Davis, Prudence Heward, Alexander Liberman, David Batchelor, Tadanori Yokoo, Frederick Sommer, Hedda Sterne, Othon Friesz, Roderic
 1049 O'Conor, Santiago Rusiñol, Richard Gerstl, Mariann Von Werefkin, Octavio Ocampo, Kay Sage, Jessica Stockholder, Gabriele Munter, Jean Benoit,
 1050 May Wilson, Jean Paul Lemieux, Jack Tworkov, Abraham Manievich, Perle Fine, Renato Guttuso, Al Held, Martial Raysse, Le Pho, Charles Reiffel,
 1051 Bernard Cohen, Rosalyn Drexler, Ilya Mashkov, Jack Youngerman, Ernst Wilhelm Nay, Ada Yunkers, Leon Spilliaert, Valerio Adami, Karl Benjamin,
 1052 Luigi Serafini, Leo Polk Smith, Osvaldo Guayasamin, Blinky Palermo, Ferdinand Du Puigaudeau, Esteban Vicente, Matsutani, Oscar Dominguez,
 1053 Yasuo Kuniyoshi, Sergei Parajanov, Joy Hester, Forrest Bess, Taro Okamoto, Maurice Tabard, Yiannis Moralis, Igor Grabar, Alex Hay, Albert
 1054 Irvin, Amadeo De Souza-Cardoso, Robert Swain, Bradley Walker Tomlin, Kishio Suga, Carlos Almaraz, Manuel Alvarez Bravo, Dan Christensen, Cyril
 1055 Power, Marcel Barbeau, Jeremy Moon, Jorge Castillo, Josef Capek, Maggie Laubser, John Alton, Albert Dubois-Pillet, William Baziotes, Joseph
 1056 Marioni, Michael Haftka, Raoul Ubac, Tony Feher, Walter Battiss, Friedel Dzubas, Varlin, Alfred Maneissier, Ron Gorchov, Tony Scherman, Alina
 1057 Szapocznikow, Nikolas Lytras, Constantine Brancusi, Walter Osborne, Max Kurzweil, Jose Guerrero, Leon Underwood, Istvan Nagy,
 1058 Albert Bloch, Ward Jackson, Piero Dorazio, Giorgio Griffa, Lourdes Castro, Lita Albuquerque, Thomas Downing, Pierre Tal-Coat, Mario Prassinos,
 1059 Panayiotis Tetsis, Robert Goodnough, Paul Feeley, Michel Majerus, Marc Vaux, Konstantinos Maleas, Vladimir Dimitrov, Meijer De Haan, Guido
 1060 Molinari, Arthur Beecher Carles, Bertalan Por, Christo Coetzee, Jamnic Holmes, Lasar Segall, Enrico Donati, Jerzy Nowosielski, Gianfranco
 1061 Baruchello, Luis Feito, Burhan Dogancay, Iosif Iser, Charles Gibbons, Thalia Flora-Karavia, Aldo Mondino, Pierre Daura, Josef Sima, Nikola
 1062 Tanev, Konrad Klapheck, Theophrastos Triantafyllidis, Edvard Weie, Gerard Fromanger, Matthias Laurenz Gräff, Victor Servranckx, Istvan Farkas,
 1063 Ramon Oviedo, Manabu Mabe, Grégoire Michonneau, Stanisław Ignacy Witkiewicz, Abidin Dino, Esteban Frances, Alberto Sughi, Olga Albizu, Behjat
 1064 Sadr, Jose De Guimaraes, Robert Nickle, Dale Hickie, Inigo Mangano-Ovalle, Antonio Carneiro, Horia Damian, Jacqueline Hick, Kuno Gonschior,
 1065 Huguette Arthur Bertrand, Ethel Léontine Gabain, Helen Dahm, Ion Nicodim, Lucy Ivanova, Gil Teixeira Lopes, Michel Carrade, Florin Maxa,
 1066 Jean-Paul Jerome, Vangel Naumovski, Graca Morais, Antonio Areal, Petros Malayan, Rodolfo Arico, Stefan Sevastre, Johannes Sveinsson Kjarval,
 1067 Ilka Gedo, Lucia Demetriade Balasescu, Natalia Dumitresco, Rene Bertholo, Vasile Kazar, Petre Abrudan, Aurel Cojan, Tia Peltz, Alvaro Lapa

1068 N Compute Used

1069 We use 8 L40 GPUs to generate images for the all text-to-image models in our work. Overall, we
 1070 use them for 16 hours per prompt, per dataset, per model to generate images. We downloaded the
 1071 images on the same machine using 40 CPU cores, a process that took about 8 hours per dataset. For
 1072 generating the image embeddings, we use the same 8 L40 GPUs, a process that took about 16 hours
 1073 per dataset. The computation of imitation score and plotting are done on single CPU core on the
 1074 same machine, a process that takes less than 30 minutes per dataset.
