Layer by Layer: Uncovering Where Multi-Task Learning Happens in Instruction-Tuned Large Language Models

Anonymous ACL submission

Abstract

 Fine-tuning pre-trained large language mod- els (LLMs) on a diverse array of tasks has be- come a common approach for building models that can solve various natural language pro- cessing (NLP) tasks. However, where and to what extent these models retain task-specific knowledge remains largely unexplored. This study investigates the task-specific information encoded in pre-trained LLMs and the effects of instruction tuning on their representations across a diverse set of over 60 NLP tasks. We use a set of matrix analysis tools to examine the differences between the way pre-trained and instruction-tuned LLMs store task-specific in- formation. Our findings reveal that while some tasks are already encoded within the pre-trained LLMs, others greatly benefit from instruction tuning. Additionally, we pinpointed the layers in which the model transitions from high-level general representations to more task-oriented representations. This finding extends our un- derstanding of the governing mechanisms of LLMs and facilitates future research in the fields of parameter-efficient transfer learning and multi-task learning.^{[1](#page-0-0)} **025**

026 1 Introduction

 While pre-trained LLMs exhibit impressive per- formance across diverse tasks and demonstrate re- markable generalization capabilities [\(Brown et al.,](#page-8-0) [2020;](#page-8-0) [Wei et al.,](#page-10-0) [2022b;](#page-10-0) [Touvron et al.,](#page-10-1) [2023;](#page-10-1) [Chowdhery et al.,](#page-8-1) [2023;](#page-8-1) [OpenAI et al.,](#page-9-0) [2024\)](#page-9-0), the representations they learn and the task-specific information encoded during pre-training remain largely opaque and unexplored.

 Recent research has investigated fine-tuning 036 strategies to adapt LLMs to specific tasks, includ- ing supervised fine-tuning on task-specific datasets [a](#page-8-2)nd instruction tuning [\(Mishra et al.,](#page-9-1) [2022;](#page-9-1) [Chung](#page-8-2)

Figure 1: An illustration of our findings using the Llama 2 7B model [\(Touvron et al.,](#page-10-1) [2023\)](#page-10-1) as an example. We show that when instruction tuning on T different tasks, the layers are divided into three functional sections: the shared layers (layers 1 to 10) form general representations shared among all tasks, the transition layers (layers 10 to 15) transition the representations into task-specific information, and the refinement layers (layers 16 to 32) continue to refine the representations toward specific tasks.

[et al.,](#page-8-2) [2022;](#page-8-2) [Sanh et al.,](#page-10-2) [2022\)](#page-10-2). While these ap- **039** proaches have shown promising results in tailor- **040** ing LLMs for improved task performance, a com- **041** prehensive understanding of their impact on the **042** learned representations is still lacking. **043**

In this study, we perform a set of analyses to **044** investigate task-specific information encoded in **045** pre-trained LLMs and the effects of instruction **046** tuning on their representations. The analysis lever- **047** ages a sub-population analysis technique called **048** Model-Oriented Sub-population and Spectral Anal- **049** ysis (MOSSA; [Zhao et al.](#page-10-3) [2022\)](#page-10-3), which provides **050** an alternative to traditional probing methods for **051** analyzing model representations within specific **052** sub-populations of the training data. MOSSA in- **053** volves comparing two models: a *control* model **054** trained on the data relevant to the sub-population **055** of interest (e.g., a particular task), and an *experi-* **056** *mental* model that is identical to the control model 057 but is also trained on additional data from different **058**

¹[We will make our code and data publicly available upon](#page-8-2) [acceptance.](#page-8-2)

 sources (e.g., multiple tasks). By analyzing the rep- resentational differences between these models, we can isolate the task-specific information encoded within the control model for the sub-population of interest.

 To compare the representations learned by differ- ent LLM variants, we leverage the Center Kernel Alignment (CKA; [Kornblith et al.,](#page-9-2) [2019\)](#page-9-2) metric. CKA measures the alignment between representa- tions in a kernel space, providing a robust measure of similarity that is insensitive to scaling and cen- tering. By using MOSSA and CKA, we investigate the following research questions:

- **072** 1. To what extent are different NLP tasks already **073** encoded in pre-trained LLMs?
- **074** 2. In what ways does instruction tuning modify **075** the representational landscape of LLMs?
- **076** 3. Do the representational effects of instruction **077** tuning generalize to unseen tasks?

 Through an extensive analysis spanning over 60 diverse NLP tasks following the Flan frame- work [\(Longpre et al.,](#page-9-3) [2023\)](#page-9-3), we shed light on the underlying mechanisms that govern the encoding and adaptation of task-specific information within LLMs under instruction tuning. A key finding of our work is the identification of three functional groups of layers: a) shared layers, in which more general information is learned and shared across tasks; b) transition layers, in which task-specific information is intensified; c) refinement layers, in which the LLMs continue to refine their represen- tations towards task-specific predictions. Our find- ings contribute to a deeper understanding of the inner workings of LLMs and hold promising im- plications for future research in parameter-efficient fine-tuning (PEFT), multi-task learning (MTL), and model compression, benefiting a wide range of NLP applications.

 We structure this study as follows: [§2](#page-1-0) describes our methodology for our analysis, while [§3](#page-2-0) outlines the experimental setup and tools used to train and analyze our LLMs. [§4](#page-2-1) then attempts to answer each of the research questions outlined above by presenting and analyzing our results. Finally, in [§5,](#page-7-0) we summarize our key findings and discuss their potential implications.

¹⁰⁵ 2 Methodology

106 We leverage the MOSSA framework introduced by **107** [Zhao et al.](#page-10-3) [\(2022\)](#page-10-3). Unlike standard probing methods [\(Belinkov et al.,](#page-8-3) [2017a,](#page-8-3)[b;](#page-8-4) [Giulianelli et al.,](#page-9-4) **108** [2018\)](#page-9-4), which build a model to predict a down- **109** stream task for quantifying encoded information, 110 MOSSA compares representations from two mod- **111** els: a control model trained on data of interest and **112** an experimental model trained on additional data **113** from different sources. Here, the data of interest **114** refers to tasks. Probing methods, while useful, can **115** be limited because they rely on different metrics to **116** evaluate performance across various tasks, making **117** it challenging to directly compare the amount of **118** information stored about tasks as diverse as sen- **119** timent analysis and translation. MOSSA, on the **120** other hand, circumvents this issue by comparing **121** the latent representations of models rather than **122** their downstream performance metrics. MOSSA **123** calculates the similarity between the representa- **124** tions of the control and experimental models, thus **125** representing the information captured from the rel- **126** evant sub-population of data through their latent **127** representations. By comparing different models to **128** each other, we can learn what information is cap- **129** tured when a subset of the data is used versus the **130** whole dataset. **131**

We use matrix analysis to compare representa- **132** tion similarity between the experimental model, **133** such as pre-trained, instruction-tuned, and corresponding single-task control models trained on indi- **135** vidual tasks. Intuitively, a high similarity between **136** the experimental and control models indicates the **137** experimental model stores task-specific informa- **138** tion learned by the control model, which was fine- **139** tuned solely on data from that task. The similarity **140** is measured using the CKA metric, which quanti- **141** fies the similarity between two representations in a **142** kernel space. **143**

Formally, let $[T]$ be an index set of tasks, and let 144 E be the experimental model and C_t be the control 145 model for task $t \in [T]$. We assume a set of inputs 146 $\mathcal{X} = \bigcup_{t=1}^{T} \mathcal{X}_t$, where each $\mathcal{X}_t = \{\mathbf{x}_{t,1}, \dots, \mathbf{x}_{t,n}\}$ 147 represents a set of input instructions for task t. For **148** simplicity, we assume that all sets have the same 149 size *n*, although this is not a strict requirement.

For each $t \in [T]$ and $i \in [n]$, we apply the experimental model $\mathbf E$ and the control model $\mathbf C_t$ to the 152 input instruction $x_{t,i}$ to obtain two corresponding 153 representations $y_{t,i} \in \mathbb{R}^d$ and $z_{t,i} \in \mathbb{R}^{d_t}$, respec- 154 tively. Here, d is the dimension of the experimental **155** model's representations, and d_t is the dimension 156 of the control model representations for task t. To **157** obtain the representations $y_{t,i}$ and $z_{t,i}$, we use the 158 last token's representation following previous work **159** **160** [\(Qiu et al.,](#page-9-5) [2024;](#page-9-5) [Wang et al.,](#page-10-4) [2024\)](#page-10-4), as LLMs **161** are decoder-only and the last token captures all

162 input information. These representations can be **163** extracted from any layers of the respective models.

164 By stacking these vectors into two matrices for

165 each task t, we obtain the paired matrices $Y_t \in$ 166 **R**^{n×d} and $\mathbf{Z}_t \in \mathbb{R}^{n \times d_t}$. We calculate the CKA

- 167 value between Y_t and Z_t following the procedure:
- **168** 169 and $K_{\mathbf{Z}_t} \in \mathbb{R}^{n \times n}$ for \mathbf{Y}_t and \mathbf{Z}_t , respectively,
- **170** using the same kernel function (e.g., linear, Gaus-**171**
- **172** Centering the kernel matrices by $K_{Y_t} = K_{Y_t} -$
- **173** 174 $K_{\mathbf{Z}_t}$, where 1 is a matrix of ones.

175 • Computing the CKA value by first compute the

- **176** Frobenius inner product of the centered Gram 177 **matrices:** HSIC($K_{\mathbf{Y}_t}, K_{\mathbf{Z}_t}$) = Tr($K_{\mathbf{Y}_t}^{\top} K_{\mathbf{Z}_t}$),
- **178** where Tr denotes the trace of a matrix. Then

179 normalize the CKA value:

180 $CKA(\mathbf{Y}_t, \mathbf{Z}_t) = \frac{\text{HSC}(K_{\mathbf{Y}_t}, K_{\mathbf{Z}_t})}{\sqrt{\text{HSC}(K_{\mathbf{Y}_t}, K_{\mathbf{Y}_t}) \cdot \text{HSC}(K_{\mathbf{Z}_t}, K_{\mathbf{Z}_t})}}$ (1)

181 While other similarity metrics like SVCCA **182** [\(Raghu et al.,](#page-10-5) [2017\)](#page-10-5) exist, they have a limitation

183 due to the constraint of being invariant to invertible

184 linear transformations, which requires the num-**185** ber of data points to be greater than the number

186 of representation dimensions. We use CKA as it **187** has shown robust results when the data sample is

188 smaller [\(Kornblith et al.,](#page-9-2) [2019\)](#page-9-2), as is sometimes **189** the case for datasets used in our work.

190 Our method provides an approach to quantify **191** the task-specific information encoded in the repre-

192 sentations of LLMs. By comparing the experimen-**193** tal model's representations with those of single-

194 task control models, we can gain insights into the

195 extent to which the experimental model captures

196 task-specific knowledge and how this knowledge **197** is distributed across its representations.

¹⁹⁸ 3 Experimental Setup

199 **Data** We use the Flan 2021 dataset [\(Wei et al.,](#page-10-6) **200** [2022a\)](#page-10-6) to fine-tune our LLMs. The Flan dataset is

201 a comprehensive collection of more than 60 NLP **202** datasets, including both language understanding

203 and generation tasks. These datasets are organized **204** into twelve task clusters, where datasets within a

 $\frac{1}{n}$ 1 $K_{\mathbf{Y}_t} - \frac{1}{n}K_{\mathbf{Y}_t}$ 1 + $\frac{1}{n^2}$ 1 $K_{\mathbf{Y}_t}$ 1, similarly for

sian, or polynomial).^{[2](#page-2-2)}

1

given cluster belong to the same task type. To en- **205** hance instruction diversity, we follow the approach **206** of [Wei et al.](#page-10-6) [\(2022a\)](#page-10-6) and use ten unique natural lan- **207** guage instruction templates for each dataset. These **208** templates provide varying descriptions of the task **209** to be performed. Our instruction tuning pipeline **210** combines all datasets and randomly samples from **211** each dataset during training. To mitigate the impact **212** of dataset size imbalances, we limit the number of **213** training examples per task cluster to 50k and use **214** [t](#page-10-7)he examples-proportional mixing scheme [\(Raffel](#page-10-7) **215** [et al.,](#page-10-7) [2020\)](#page-10-7) with a mixing rate maximum of 3,000 **216** per task. This means that no task receives addi- **217** tional sampling weight for examples in excess of **218** 3,000. We provide further details about the dataset **219** in Appendix [A.](#page-11-0) **220**

Models We have two types of models: the exper- **221** imental model **E**, fine-tuned using all T available 222 tasks, and the single-task model C_t for $t \in [T]$, 223 fine-tuned only on the t-th task. In some exper- **224** iments, the model E can also be the pre-trained **225** model. We use the Llama 2 models [\(Touvron et al.,](#page-10-1) **226** [2023\)](#page-10-1) as the starting training checkpoint for both E **227** and C_t . Specifically, we use the 7B variant, which 228 consists of 32 layers and 4096 hidden dimensions. **229**

Training We use LoRA [\(Hu et al.,](#page-9-6) [2022\)](#page-9-6) for fine- **230** tuning our LLMs, with the rank r set to 8. We 231 use the AdamW optimizer [\(Loshchilov and Hutter,](#page-9-7) **232** [2019\)](#page-9-7) with a learning rate of 5×10^{-5} for fine-
233 tuning the instruction dataset. We use the same vo- **234** cabulary, tokenizer, and learning rate scheduler for **235** Llama 2-7B as in [Touvron et al.](#page-10-1) [\(2023\)](#page-10-1). We train **236** the multi-task model E (which we refer to as Llama **237** 2-SFT in our experiment) for a maximum of 100K **238** steps and the single-task models C_t for a maximum 239 of 10K steps, using validation set cross-entropy **240** loss for early stopping. Our multi-task models are **241** trained on four NVIDIA A100 GPUs with a batch **242** size of 16 per GPU, while single-task models are **243** trained on one NVIDIA A100 GPU with a batch **244** size of 16.We use PyTorch [\(Paszke et al.,](#page-9-8) [2019\)](#page-9-8), 245 the HuggingFace library [\(Wolf et al.,](#page-10-8) [2020\)](#page-10-8), and **246** the LLaMA-Factory library [\(Zheng et al.,](#page-10-9) [2024\)](#page-10-9) for **247** all model implementations and LoRA fine-tuning. **248**

4 Experiments and Results **²⁴⁹**

To shed light on the underlying mechanisms of **250** MTL [\(Caruana,](#page-8-5) [1997\)](#page-8-5) in LLMs, we start by ex- **251** amining what NLP tasks are encoded in the pre- **252** trained LLM representations, establishing a base- **253**

²For linear kernel, which is what we use in our experiment, $K_{\mathbf{Y}_t} = \mathbf{Y}_t \mathbf{Y}_t^{\top}$, and $K_{\mathbf{Z}_t} = \mathbf{Z}_t \mathbf{Z}_t^{\top}$.

Figure 2: Distribution of CKA similarities across all layers for the pre-trained Llama 2 model and the instructiontuned Llama 2-SFT model. The boxplots illustrate the spread and variation of CKA similarities between each model and the control models across different tasks. The comparison between the two models highlights the impact of instruction tuning on shaping task-specific representations in different layers.

Figure 3: Distribution of CKA similarities across all layers for the pre-trained Llama 2 model and the instructiontuned Llama 2-SFT model, grouped by different task clusters.

 line for comparison with the instruction-tuned model ([§4.1\)](#page-3-0). Then, using matrix analysis methods, we contrast the representational properties of the pre-trained and instruction-tuned LLMs to under- stand the effects of instruction tuning ([§4.2,](#page-4-0) [4.3,](#page-5-0) and [4.4\)](#page-5-1). Finally, we evaluate the generalization of our findings to unseen tasks ([§4.5\)](#page-6-0).

261 4.1 Task Information in Pre-trained LLMs

262 To identify task-relevant information in pre-trained **263** LLMs, we compared representations from the pretrained Llama 2 model with task-specific fine-tuned **264** models $({\lbrace C_t \rbrace}_t)$. Figure [2](#page-3-1) shows the distribution 265 of CKA similarities across all tasks and layers for **266** the Llama 2 model. The CKA similarities between **267** pre-trained Llama 2 and control models generally **268** decrease through higher layers. **269**

Llama 2 maintains high CKA similarities in ear- **270** lier layers, and since CKA compares against con- **271** trol models fine-tuned on individual tasks, this sug- **272** gests that representational changes in the earlier **273** layers are minimal across tasks. However, we ob- **274** serve widespread variance in CKA values across **275** different tasks in the middle and higher layers, sug- **276** gesting that some tasks are better captured in the **277** Llama 2 model representations than others. **278**

To gain a more fine-grained understanding, we **279** analyzed the CKA results at the task cluster level, **280** where each cluster consists of a group of similar **281** tasks. The Flan dataset organizes tasks into 12 dif- **282** ferent clusters, detailed in Appendix [A.](#page-11-0) We present **283** CKA results for a selection of representative clus- **284** ters in Figures [3,](#page-3-2) with the full results provided in **285 Appendix [B.2.](#page-11-1)** 286

For clusters like closed-book QA, commonsense **287** reasoning, paraphrase detection, and sentiment **288** analysis, which heavily rely on general linguistic **289** and semantic understanding, the CKA similarity **290** for Llama 2 is high. This indicates that pre-trained **291** models already encode these tasks well in their **292** representations. Conversely, for clusters like coref- **293** erence resolution, reading comprehension, struc- **294** tured data to text generation, summarization, and **295** translation, which require specialized, structured, **296** or domain-specific knowledge involving complex **297** transformations or extended context management, **298**

Figure 4: t-SNE visualizations of the representations for each task cluster in different layers of the pre-trained Llama 2 model and the instruction-tuned Llama 2-SFT model. Each subplot presents the t-SNE projection of the representations, color-coded by task cluster, for a specific layer of the respective model. "Reading comp." denotes reading comprehension tasks, and "reading comp. w/ c.s." denotes reading comprehension tasks with commonsense reasoning.

Figure 5: Average number of dimensions required to explain 99% of the representational variance across all tasks, as a function of the layer number.

299 the CKA similarities are low, suggesting that next **300** token prediction at pre-training is insufficient for **301** encoding these tasks.

302 4.2 Impact of Instruction Tuning

 Mapping Layers to Their Functionality To in- vestigate how instruction tuning affects the rep- resentations learned by LLMs, we compared the instruction-tuned model (Llama 2-SFT) with task- specific fine-tuned control models. As illustrated in Figure [2,](#page-3-1) the CKA similarities between Llama 2- SFT and the control models do not decrease as sig- nificantly as those for the pre-trained model (Llama 2) across layers. In the early layers (1 to 9), we observe that for many tasks, the CKA scores are lower 312 for Llama 2-SFT compared to Llama 2, indicat- **313** ing that Llama 2-SFT representations diverge from **314** those of the control models, which were fine-tuned **315** on individual tasks (thus specializing in them). This **316** suggests that, unlike the Llama 2 model, training **317** Llama 2-SFT on a high number of tasks encourages **318** it diverge from the control models' representations **319** and learn more general representations in the lower **320** layers, a characteristic typical of MTL models. We **321** denote layers 1-9 as "shared layers", as our find- **322** ings suggest their representations are shared across **323** tasks, similar to more studied MTL models. **324**

In the middle layers (10-15), there is a significant **325** transition, with the Llama 2-SFT model exhibiting **326** high similarity to *all control models*. This indi- **327** cates that these layers encode a high degree of task- **328** specific information, as their representations are **329** almost identical to those of the specialized control **330** models. We denote layers 10-15 as "transitional **331** layers", as our findings suggest the transition to **332** task-specific representations occurs within these **333** layers. This trend continues, albeit to a lesser ex- **334** tent, up to the final layers (16-32), which we denote **335** as "refinement layers", as they keep refining the **336** representations up to the final prediction. Based on **337** our findings, we can map each layer in the Llama **338** 2-SFT model to its corresponding function with re- **339** spect to MTL (see Figure [1\)](#page-0-1). While previous work **340**

Figure 6: Pearson correlation results between the CKA similarities for all tasks and their reading difficulty among all layers. Higher values in reading difficulty measures correspond to greater reading difficulty.

 [\(Wei et al.,](#page-10-6) [2022a;](#page-10-6) [Chung et al.,](#page-8-2) [2022\)](#page-8-2) has empiri- cally demonstrated the effectiveness of instruction tuning for improving performance on a variety of NLP tasks, to the best of our knowledge, we are the first to propose such a mapping. In the following sections, we provide additional analyses to further validate our mapping.

 Examining individual task clusters Figures [3](#page-3-2) demonstrates that for tasks that are not well en- coded in the pre-trained Llama 2 (e.g., structured data to text generation, translation), the CKA sim- ilarities from the instruction-tuned Llama 2-SFT remained high throughout all transition and refine- ment layers (10-32). Instruction tuning for these tasks induced significant representational shifts, adapting the model's internal structure to meet their specific demands. This aligns with prior work [\(Aghajanyan et al.,](#page-8-6) [2021\)](#page-8-6) showing that tasks re- quiring more sophisticated reasoning and modeling benefit greatly from task-specific tuning of pre-trained language models.

362 4.3 Representation Clustering and Variance **363** Analysis

 To further investigate representational differences, we used t-SNE [\(Van der Maaten and Hinton,](#page-10-10) [2008\)](#page-10-10) to visualize task clusters across layers. Figure [4](#page-4-1) presents a representative selection of layers, includ- ing a shared layer (layer 1), transition layers (layers 10 and 15), and refinement layers (layers 20 and 32). The full results for all layers are provided in Appendix [B.2.](#page-11-1) In the first layer, both Llama 2 and Llama 2-SFT exhibit similar clustering. How- ever, as we move to the transition layers, from layers 10 to 15, the Llama 2-SFT model forms more distinct task clusters compared to the Llama 2 model. This is further evidence that instruction **376** tuning transforms the representations towards task- **377** specificity in the transition layers. This clustering **378** becomes increasingly pronounced in refinement **379** layers, highlighting the effectiveness of instruction **380** tuning in differentiating task-specific information **381** and enhancing the ability to specialize representa- **382** tions for different tasks. **383**

To quantify these differences, we performed vari- **384** ance analysis on the representations. We sought **385** to determine if the model's ability to retain a large **386** amount of task-specific information for many tasks **387** affects its representation complexity. We analyzed **388** the number of principal components required to **389** explain 99% of the variance in representation ma- **390** trices across layers. The average number of com- **391** ponents over all tasks is presented in Figure [5.](#page-4-2) In **392** the shared layers, both Llama 2 and Llama 2-SFT **393** models require a similar number of dimensions. **394** Then, in the transition layers, Llama 2-SFT model **395** begins to require more dimensions, suggesting it **396** captures more complex task-specific information. **397** This further demonstrates that the transition layers **398** are indeed the layers where the transition to the **399** task-specific representations occurs. **400**

4.4 Assessing Task Specific Information via **401** Readability **402**

In the preceding sections, we observed that the **403** Llama 2 model exhibited a high variance in the **404** amount of task-specific information stored across **405** different tasks. In contrast, the Llama 2-SFT model **406** demonstrated a low variance, storing a high level **407** of task-specific information in its transition and **408** refinement layers. While the Llama 2-SFT model **409** exhibited low variance, we aimed to investigate the **410** task priorities within the representation and identify **411**

Figure 7: Distribution of CKA similarities across all layers for the pre-trained Llama 2 model and the instructiontuned Llama 2-SFT model on unseen tasks.

 features that could predict it. Previous research by [Zhao et al.](#page-10-3) [\(2022\)](#page-10-3) has shown that when masked lan- guage models, such as BERT [\(Devlin et al.,](#page-9-9) [2019\)](#page-9-9), are trained on data from multiple domains, they tend to allocate their parameters to store domain- specific information. Unlike our approach, which examines instruction-level representations using the last token of an instruction, their study used the MOSSA method to analyze contextualized word embeddings, allowing them to focus on domain- specific words. We followed a similar analysis to examine task-specific information, which is strongly related to domain-specific information (as tasks can be viewed as domains). We used read- ability as a proxy for domain-specific information, relying on the finding by [Pitler and Nenkova](#page-9-10) [\(2008\)](#page-9-10) that texts with more domain-specific and less com- monly used words tend to have lower readability, resulting in higher reading difficulty scores.

 We used two highly popular reading difficulty measures: the Flesch-Kincaid grade level score [\(Kincaid et al.,](#page-9-11) [1975\)](#page-9-11) and the Coleman-Liau Index [\(Coleman and Liau,](#page-9-12) [1975\)](#page-9-12). The Flesch-Kincaid score assesses text readability based on factors like average sentence length and syllables per word, with lower scores indicating easier reading. Sim- ilarly, the Coleman-Liau Index estimates the re- quired reading grade level based on characters, words, and sentences, with higher values corre- sponding to greater difficulty. We conducted Pear- son correlation analyses between CKA similarity and reading difficulty measures for all tasks across all layers. As illustrated in Figure [6a,](#page-5-2) we found a positive correlation between CKA similarity and the Flesch-Kincaid score for Llama 2-SFT. This correlation rapidly increases between layer 10 and layer 15 (the transition layers) and then saturates.

These transitional layers are where task special- **449** ization transformations occur, as discussed earlier. **450** This correlation is much weaker for the Llama **451** 2 model. A similar pattern is observed with the **452** Coleman-Liau Index, as shown in Figure [6b.](#page-5-2) These **453** findings suggest that instruction-tuned models en- **454** code more information for tasks with more task- **455** specific vocabulary, as measured by their texts' **456** readability indices. These findings thus suggest **457** that instruction-tuned models encode and preserve **458** task-specific information in the transition layers **459** and retain it through the refinement layers, com- **460** plementing our earlier findings. Moreover, we pre- **461** viously noted that one of the advantages of CKA, **462** compared to other similarity metrics, is its mini- **463** mal requirement for a large number of data points **464** in the analysis. To verify this, we conducted a **465** correlation analysis between data size and CKA **466** similarity, with the results presented in Figure [10](#page-16-0) 467 in Appendix [B.2.](#page-11-1) The analysis revealed no clear **468** correlation between data size and CKA similarities, **469** indicating that the number of data points used for **470** CKA per task does not impact the CKA similarity. **471**

4.5 Evaluating Representations on Unseen **472** Tasks **473**

While our previous analyses focused on evaluating **474** representations against models trained on the same **475** task data, it is crucial to examine how well our find- **476** ings generalize to unseen tasks. To investigate this, **477** we held out a set of seven tasks, including conversa- **478** tional question answering, question classification, **479** math problems, linguistic acceptability, and word **480** sense disambiguation (details in Appendix [A\)](#page-11-0). Our 481 instruction-tuned models had no exposure to any **482** of these seven tasks during training. **483**

The CKA similarity results in Figure [7](#page-6-1) reveal an **484**

 interesting pattern. For the lower layers (up to layer 12), the Llama 2 model exhibited slightly higher CKA similarities than Llama 2-SFT for several tasks, similar to what we find in [§4.2.](#page-4-0) This indi- cates that while the Llama 2-SFT model was not trained using these tasks, it produced more diver- gent representations in lower layers and thus more general than the ones produced by Llama 2 (we re- fer the reader to shared layers discussion in [§4.2](#page-4-0) for more details). However, as we move to the middle and higher layers responsible for encoding more specialized, task-specific knowledge, the Llama 2-SFT model began matching and ultimately sur- passing the CKA similarities of the Llama 2 model. We can also see high variances between task simi- larities for both models, showing that we can not identify transition layers for Llama 2-SFT in this setup, just shared and refinement layers. These findings suggest that in addition to being trained on instructions, instruction-tuned models benefit from more general and thus better feature representations in their lower layers, which boost their performance for unseen instruction-based tasks compared to pre-trained LLMs.

⁵⁰⁹ 5 Discussion

 Our study offers comprehensive insights into the impact of instruction tuning on the representations learned by LLMs. Previous work has discussed the benefits of instruction tuning [\(Wei et al.,](#page-10-0) [2022b;](#page-10-0) [Chung et al.,](#page-8-2) [2022;](#page-8-2) [Longpre et al.,](#page-9-3) [2023\)](#page-9-3), but ours is the first to analyze their effects from a represen-tational perspective.

 Our analysis revealed that LLMs instruction- tuned on multiple tasks learned different represen- tations in the lower layers compared to LLMs tuned on individual tasks. Similar to MTL, such repre- sentations can be shared and leveraged across tasks [\(Maurer et al.,](#page-9-13) [2016\)](#page-9-13). Our analysis uncovered a key novel finding – we observed clear differences between pre-trained and instruction-tuned models, with the most significant representational transfor- mations occurring in the middle transitional layers. This finding highlights the critical role of middle layers in encoding the specialized task knowledge induced by instruction tuning. Similarly, previous studies in multilingual settings have also identi- fied language-neutral transformations in the middle [l](#page-10-11)ayers of the network [\(Muller et al.,](#page-9-14) [2021;](#page-9-14) [Zhao](#page-10-11) [et al.,](#page-10-11) [2023\)](#page-10-11). Furthermore, our analysis suggests that in the refinement layers, instruction-tuned models continue to shape representations toward spe- **535** cific tasks but without substantial representational **536** changes with respect to task-specific information. **537** Overall, our finding about functionality for differ- **538** ent layers in LLMs generally aligns with previous **539** findings on BERT, which have shown that lower **540** layers are more general, while upper layers are **541** known to be more task-specific [\(Rogers et al.,](#page-10-12) [2020;](#page-10-12) **542** [Merchant et al.,](#page-9-15) [2020\)](#page-9-15). **543**

Our correlation analysis also revealed insights **544** into the relationship between representations and **545** task complexity. Instruction-tuned models exhib- **546** ited a positive correlation with reading complexity **547** measures in the transition and refinement layers, **548** suggesting better encoding of task-specific infor- **549** mation for tasks with more specific vocabulary – 550 a capability not observed in pre-trained models. **551** Notably, instruction tuning enabled models to pre- **552** serve and enhance task-specific information across **553** a broader range of layers, as evidenced by higher **554** CKA similarities compared to control models. Our **555** evaluation of unseen tasks further underscored the **556** benefits of instruction tuning for improving general- **557** ization, with instruction-tuned models outperform- **558** ing their pre-trained counterparts in deeper layers **559** responsible for encoding complex task knowledge. **560** This aligns with empirical evidence from [Wei et al.](#page-10-6) **561** [\(2022a\)](#page-10-6) but also highlights how representational **562** changes facilitated by instruction tuning strengthen **563** cross-task transfer capabilities. **564**

6 Conclusion **⁵⁶⁵**

Our study used several analyses to investigate **566** how instruction tuning shapes representations in **567** LLMs. These analyses revealed that unlike the **568** pre-trained LLM (Llama 2), the instruction-tuned **569** model (Llama 2-SFT) retained a high amount of **570** task-specific information for all tasks from the mid- **571** dle layers onward. Moreover, we were able to map **572** the layers of Llama 2-SFT into three groups based **573** on their functionality: shared layers (layers 1-9), **574** transition layers (10-15), and refinement layers (16- **575** 32). In addition to expanding our understanding **576** of LLMs, such mapping can greatly benefit future **577** research in the fields of PEFT, MTL, and model **578** compression. We also demonstrated that our map- **579** ping does not generalize to unseen tasks, revealing **580** that a potential additional reason for the strong gen- **581** eralization capabilities of instruction-tuned models **582** to unseen tasks can be related to their multi-task **583** nature of producing more general representations. **584**

⁵⁸⁵ Limitations

 While our study provides valuable insights into the impact of instruction tuning on the representations learned by LLMs, there are several limitations that should be considered.

 Firstly, the instruction tuning in our experiments was implemented using LoRA instead of full fine- tuning. While LoRA is computationally efficient and effective in many scenarios, it may not capture the full range of representational changes that full fine-tuning can achieve. This limitation might have influenced the depth of insights into how instruc-tion tuning affects the model representations.

 Secondly, our study exclusively used the Llama 2 model due to limited computational resources available. Although Llama 2 is a powerful and widely used LLM, relying on a single model limits the generalizability of our findings. Different mod- els may exhibit varied representational dynamics and responses to instruction tuning. Expanding our analysis to include multiple models from different architectures would provide a more comprehensive understanding of these effects.

 Additionally, we conducted our experiments on the 7B parameter version of Llama 2. While this model size is substantial, it is not the largest avail- able. Larger models, with their greater capacity and potentially different representational capabilities, might show different patterns in response to fine- tuning. Investigating multiple model sizes would help ascertain whether the observed trends hold across different scales.

 Moreover, our experiments focused solely on NLP tasks and did not explore fine-tuning on code or other specialized domains. Coding tasks of- ten involve unique representational challenges and might reveal different insights into the impact of fine-tuning. Including such tasks in future work would broaden the scope and applicability of our findings.

⁹²² A Dataset Details

 This appendix provides a detailed overview of the datasets used in this study. We followed [Wei et al.](#page-10-6) [\(2022a\)](#page-10-6) and organized all tasks into the following task clusters:

- **927** Closed-book Question Answering (QA) re-**928** quires models to answer questions about the **929** world without direct access to the answer-**930** containing information.
- **931 Commonsense Reasoning** tests the capacity **932** for physical or scientific reasoning infused **933** with common sense.
- **934** Coreference Resolution identifies expres-**935** sions referring to the same entity within a **936** given text.
- **937** Natural Language Inference (NLI) focuses **938** on the relationship between two sentences, **939** typically evaluating if the second sentence is **940** true, false, or possibly true based on the first **941** sentence.
- **942 Paraphrase Detection** involves evaluating if **943** two sentences have the same meaning. While **944** it can be considered a form of bidirectional **945** entailment, it remains distinct from NLI in **946** academic contexts.
- **947 Reading Comprehension** assesses the ability **948** to answer questions based on a given passage **949** containing the necessary information.
- **950** Reading Comprehension with Common-**951** sense merges the tasks of reading comprehen-**952** sion and commonsense reasoning.
- **953 Sentiment Analysis** is a traditional NLP task **954** that determines whether a text expresses a pos-**955** itive or negative sentiment.
- **956** Struct-to-Text involves generating natural **957** language descriptions from structured data.
- **958** Translation is the task of translating text from **959** one language to another.
- **960** Summarization involves creating concise **961** summaries from longer texts.
- **962** Unseen clusters uses the original miscella-**963** neous task cluster from [Wei et al.](#page-10-6) [\(2022a\)](#page-10-6) **964** which includes:

We provide tasks contained in each cluster in **971** Table [1.](#page-12-0) 972

B Additional Results **⁹⁷³**

B.1 Results on Model Evaluation 974

We provide the results on all control models and **975** instruction-tuned Llama 2-SFT in Table [3](#page-13-0) (for nat- **976** ural language understanding tasks) and Table [4](#page-14-0) (for **977** natural language generation tasks). To further eval- **978** uate the validness of our instruction tuning, we **979** also benchmark our models on two popular bench- **980** mark datasets: MMLU [\(Hendrycks et al.,](#page-9-16) [2021\)](#page-9-16) **981** and BBH [\(Suzgun et al.,](#page-10-13) [2022\)](#page-10-13). We provide re- **982** sults in Table [2.](#page-12-1) We can see that Llama 2-SFT **983** outperforms Llama 2 on both of these benchmarks. **984**

B.2 Results on Analysis 985

Here we provide additional results on our analysis. **986** We provide the distribution of CKA similarities for **987** all layers by tasks clusters in Figure [8](#page-15-0) and [9.](#page-16-1) We **988** also provide Pearson correlation results between **989** the CKA similarities for all tasks and their data **990** size among all layers in Figure [10.](#page-16-0) Lastly, we **991** provide the t-SNE visualizations of representations **992** in different layers of Llama 2 in Figure [11.](#page-17-0) We **993** provide the same visualizations for Llama 2-SFT **994** in Figure [12.](#page-18-0) **995**

Table 1: Dataset details grouped by task clusters. For WMT'16, we include En–De, En–Tr, En–Cs, En–Fi, En–Ro, and En–Ru translation pairs. For all details about each dataset including the data set size, please refer to [Wei et al.](#page-10-6) [\(2022a\)](#page-10-6).

Table 2: Results for Llama 2 and Llama 2-SFT on MMLU and BBH. We use a 0-shot evaluation for MMLU to assess our models. For BBH, we follow the default evaluation protocol and use a 3-shot evaluation.

Table 3: Performance metrics grouped by natural language understanding task clusters for Llama 2-SFT and control models (Llama 2 model individually fine-tuned on each task). "Read. Comp. w/ Commonsense" denotes reading comprehension with commonsense.

Table 4: Performance metrics grouped by natural language generation task clusters for Llama 2-SFT and control models (Llama 2 model individually fine-tuned on each task).

Figure 8: Distribution of CKA similarities across all layers for the pre-trained Llama 2 model and the instructiontuned Llama 2-SFT model, grouped by different task clusters.

Figure 9: Distribution of CKA similarities across all layers for the pre-trained Llama 2 model and the instructiontuned Llama 2-SFT model, grouped by different task clusters.

Figure 10: Pearson correlation results between the CKA similarities for all tasks and their data size among all layers.

Figure 11: t-SNE visualizations of the representations for each task cluster in different layers of the pre-trained Llama 2 model. Each subplot presents the t-SNE projection of the representations, color-coded by task cluster, for a specific layer of the respective model. "Reading comp." denotes reading comprehension tasks, and "reading comp. w/ c.s." denotes reading comprehension tasks with commonsense reasoning. We omit layer 10 and 15 to fit in one page and as we have provided them earlier.

Figure 12: t-SNE visualizations of the representations for each task cluster in different layers of the instruction-tuned Llama 2-SFT model. Each subplot presents the t-SNE projection of the representations, color-coded by task cluster, for a specific layer of the respective model. "Reading comp." denotes reading comprehension tasks, and "reading comp. w/ c.s." denotes reading comprehension tasks with commonsense reasoning. We omit layer 10 and 15 to fit in one page and as we have provided them earlier.
