Towards Verifiable Text Generation with Symbolic References

Anonymous ACL submission

Abstract

Large language models (LLMs) have demonstrated an impressive ability to synthesize plausible and fluent text. However they remain vul-004 nerable to hallucinations, and thus their outputs generally require manual human verification for high-stakes applications, which can be time-007 consuming and difficult. This paper proposes symbolically grounded generation (SymGen) as a simple approach for enabling easier validation of an LLM's output. SymGen prompts an LLM to interleave its regular output text with explicit symbolic references to fields present in some conditioning data (e.g., a table in JSON format). The references can be used to display the provenance of different spans of text 015 in the generation, reducing the effort required 017 for manual verification. Across data-to-text and question answering experiments, we find that LLMs are able to directly output text that makes use of symbolic references while maintaining fluency and accuracy. In a human study we further find that such annotations can streamline 022 human verification of machine-generated text.

1 Introduction

Many applications of generative AI involve generating text based on structured data (e.g, tabular data, surveys, API outputs, etc.) that is known (or assumed) to be trustworthy. For example, newspapers may be interested in generating summaries of sports games based on official match statistics, and search providers would want generative search engines to ground its output in search results. These applications require conditional text generation that is fluent, accurate, and verifiable with respect to the conditioning information. Large language models (LLMs) have advanced to the point where they can sometimes be relied upon to generate fluent- and faithful-enough summaries of text and other structured data. However they remain far from perfect (Liu et al., 2023; Yue et al., 2023), and insofar as high-stakes applications will almost certainly require a human to manually verify

Figure 1: Compare a standard LLM-generated (A) with a SymGen (B, ours) description of a basketball game, based on match statistics. SymGen imbues spans of generated text (highlighted in blue) with symbolic references to the source data, enabling easier verification: e.g., when hovering over a span, the number "30" displays a tooltip indicating the value it is referencing, alongside a link to its source (highlighted in yellow).

that an LLM's generation is accurate with respect to its conditioning information, there is a need to develop frameworks that maintain the fluent and accurate few-shot generation capabilities of LLMs while enabling streamlined human verification of the model's output.

This paper proposes *symbolically grounded generation* (SymGen) as a step towards verifiable text generation with LLMs. Given a string representation of data in a structured but human-readable format (e.g., JSON, YAML, etc.), we prompt the LLM to generate the output with explicit symbolic references into the provided data structure instead of generating the text directly. The references are then rendered using a parser, which can faithfully represent values from the original data, and can moreover be used to include visual cues that enable a user to readily verify the provenance of a particular

1 STRUCTURED DATA	JSON) Prom	pted LLM	2 SYMBOLIC GENERATION Parser 3 RENDERED TEXT	
visitor: name: Trail Bla city: Portlan wins: 33 losses: 30 pts: 115 pts_qtr1: 30 pts_qtr2: 22	ers home: name:		The [(visitor.city]) ((visitor.name)) (((visitor.wins)) - ((visitor.losses))) faced off against the ((home.city)) ((home.name)) (((thome.wins)) - ((home.losses))) in a thrilling game that ended with the Raptors winning ((home.pts)) - ((visitor.pts)). The game was a close contest throughout, with the Raptors leading by just one point at the end of the first quarter ((home.pts.qtr1)) - ((visitor.pts.qtr1)) and extending their lead slightly by halftime (((home.pts.qtr1+home.pts.qtr2))). - (((visitor.pts.qtr1+visitor.pts.qtr2))).	41 - 19) in a he Raptors as a close aptors leading by first quarter 31

Figure 2: Overview of the proposed symbolically grounded generation (SymGen) pipeline, on an example generated by GPT-4. Given the structured data input (1), we use a prompted LLM to generate a response (2) that contains symbolic references into the data (e.g., the variable visitor.city marked by (3). A parser then substitutes the symbolic references with their corresponding values in the structured data (e.g., Portland for visitor.city) to obtain the final rendered text (3). Our SymGen pipeline can implicitly leverage the input data to generate prose without any symbolic references (e.g., the span marked by (3). It can also generate transformations of existing variables (e.g., adding up two numbers, marked by (5)) to create unavailable data in the source, while preserving references to the original variables.

span of text. See Fig. 2 for an overview. In contrast to classic templated approaches for text generation (Kukich, 1983; McKeown, 1992; McRoy et al., 2000), SymGen instead offloads the template specification process to an LLM. We exploit the fact that LLMs have likely been sufficiently exposed to such kind of templated text during pretraining that they are able perform zero- and few-shot text generation with symbolic references across multiple domains.

091

Experiments on zero- and few-shot data-to-text generation and question answering indicate that LLMs can be prompted to generate fluent text that is interleaved with symbolic references which explicitly refer to data fields. Further, in a human study, we find that the annotations enabled by Sym-Gen simplify the process of post-hoc verification, both as perceived by the user and by reducing the average verification time by 20%.

2 Symbolic References for Verifiable Text Generation

Templated text is ubiquitous in the wild. In the context of software engineering, programming languages such as Python expose multiple mechanisms for the specification of templated strings,¹ and web frameworks such as Angular rely on them extensively. These templated documents allow one to combine regular prose with symbolic references that can be grounded to some (perhaps implicit) context at a later time. Thus, LLMs that have been pretrained on vast amounts of web data should in principle be capable of generating responses that include such symbolic references, at least if they are provided a schema with the fields they can reference. This paper explores the effectiveness of such symbolic generation in settings where the LLM must generate a piece of text based on some structured input. In turn, such references can help users verify whether an LLM correctly interpreted the input data structure (Fig. 1B).

Our SymGen pipeline is shown in Fig. 2, and consists of two stages:

Stage 1. In the symbolic reference generation stage, we provide the LLM with the structured data, alongside a prompt of what it should generate (e.g., "Generate a biography about a person whose description is given in JSON. [...]"). While the data may be provided in any structured format, we mainly focus on JSON due to its ubiquity.² Within the prompt, we ask that the LLM generate its response using symbolic references, i.e., snippets of inline code that refer to the provided data structure. The syntax for the resulting text in symbolic form may vary, but in preliminary experiments we found that Jinjastyle³ expressions led to robust results (in the sense that the LLM will usually not make mistakes) while also allowing the LLM to perform simple transformations on the provided data (e.g., number formatting, simple calculations; see Fig. 2).

Stage 2. In the *rendering stage*, all references are resolved by replacing them with their corresponding values using a parser. Note that these symbolic expressions may be more complex than a pointer into the data structure, e.g., they might compute a sum (see Fig. 2). In the event that an LLM generated a reference that cannot be resolved, one can resolve it to a default value, e.g., "undefined." While

²Preliminary experiments using YAML, which is more compact insofar as API token consumption is concerned, showed similarly positive results.

³https://jinja.palletsprojects.com

the final rendered text could be presented directly 127 to the user, one could also exploit the intermediate 128 symbolic representation to display an augmented 129 version of the text which shows the correspondence 130 between the rendered references and the underlying source data. One could thus see SymGen as similar 132 in spirit to citation-enabled LLMs (Liu et al., 2023; 133 Yue et al., 2023; Gao et al., 2023), except that our 134 approach focuses on providing very precise and 135 easy to validate citations with respect to some data. 136

Strategies for symbolic reference generation. We consider two possible symbolic reference generation strategies for SymGen. The first is the *direct* strategy shown in Fig. 2, which instructs the LLM to directly generate text with symbolic references given the structured input. While in principle (given the right data and appropriate templates) any response given by regular generation could also be generated using symbolic references, in practice there might be performance degradation if reasoning or writing are more unnatural for the model when working directly in "symbolic form space".

Hence, we also consider an *indirect* strategy, where we prompt the LLM to first generate the text in regular prose (i.e., without any symbolic references), and then prompt it to rewrite it using symbolic references afterwards. The advantage of the indirect approach is that it should maintain the same text quality as regular generation as long as converting regular prose into symbolicallyaugmented text is no harder than generating the regular text in the first place; the caveat is that this approach can be more costly under APIs that charge on a per-token basis, as it requires roughly twice the amount of tokens to be generated. We also found this strategy to be unreliable with weaker LLMs such as GPT-3.5,⁴ so we only employ this with GPT-4 as the base LLM. Finally, as a baseline, we also consider an approach that prompts the LLM to generate regular text without any references.

3 Evaluation

The main empirical study in this work aims to understand whether SymGen maintains the same quality as the baseline when using symbolic references; we are not necessarily interested in improving upon the baseline (although in some cases we do observe improvements), as our primary aim is to improve verifiability, which can in principle be achieved if we incorporate references without changing the content of the generation. Our analysis is conducted on five datasets, which are shown in Tab. 10 of App. F.1. We explore four settings: traditional data-to-text (§3.1), counterfactual obituary generation (§3.2), question-answering (QA) over financial information (§3.3), and arithmetic word problems (§3.4). We consider both zero- and few-shot settings for each of those tasks. 175

Depending on the nature of the task (e.g., complexity, size of the structured data, etc.), we evaluate our approach on a mix of GPT-3.5 (with 4K or 16K context windows) and GPT-4 (with 8K or 32K context windows). The full experimental setups, including the prompts, are given in App. F. Anecdotally, we found that extensive experiments with different prompts were not necessary to get LLMs to perform symbolic generation; we expect that further (perhaps task-specific) improvements are possible with more prompt engineering.

3.1 Data-to-text

SymGen is similar in spirit to data-to-text methods, where the goal is to generate some text based on structured data. Classical approaches to this problem consist of designing a template based on the schema of the data, and populating it with the values of a datapoint at runtime (Kukich, 1983; McKeown, 1992; McRoy et al., 2000). However, relying solely on the schema of the data tends to yield formulaic text. Neural approaches to data-totext generation (Wiseman et al., 2017, 2018; Wang, 2019; Yin and Wan, 2022) improve on this by generating text that is datapoint-dependent, but achieve this by training on data-to-text datasets. We revisit this setting in the context of zero- and few-shot data-to-text generation with LLMs.

Datasets. We first consider SynthBio (Yuan et al., 2021), a collection of synthetically constructed *fic-tional* entities, described in terms of a collection of key–value pairs, which has been used in prior work on templated generation with finetuned models (Zhang et al., 2022). The task is to generate a textual description of the entity. We also consider the Rotowire (Wiseman et al., 2017) dataset, where the objective is to generate a summary of a basketball game given its box (individual player statistics) and line (aggregate team statistics) scores. The Rotowire dataset presents a challenging testbed for our approach, since its data structure is substantially more complex than the previous task (i.e., there are many more fields in each datapoint) and it

⁴Specifically, we found that GPT-3.5 would often behave as in the direct SymGen strategy, despite being prompted and given examples of the desired, indirect SymGen behavior.

			BLEU	BERT F1	ER	GER
.5-4K	0-shot	Baseline Direct	$31.15 \\ 26.64$	$53.43 \\ 47.88$	$0.00 \\ 0.28$	$0.00 \\ 0.00$
GPT-3.5-4K	2-shot	Baseline Direct	$30.98 \\ 32.43$	$54.66 \\ 53.32$	$0.00 \\ 3.30$	$\begin{array}{c} 0.00\\ 0.09 \end{array}$
4-8K	0-shot	Baseline Direct Indirect	30.08 33.31 35.02	54.27 54.07 55.58	$0.00 \\ 0.00 \\ 0.00$	$0.00 \\ 0.00 \\ 0.00$
GPT-4-8K	2-shot	Baseline Direct Indirect	32.43 36.83 37.56	56.39 57.71 57.88	0.00 2.11 3.21	$0.00 \\ 0.00 \\ 0.00$

Table 1: Results on the SynthBio (Yuan et al., 2021) dataset. We report BLEU (Papineni et al., 2002) and BERTScore F1 (BERT F1; Zhang et al., 2020) against the reference biographies. We also report the (general) error rate (ER (%)) and the global error rate (GER (%)). See §3.1 for a discussion.

relies on more specific in-domain knowledge (i.e., understanding how to read basketball box scores charts). To keep LLM API costs manageable, we sample 100 examples from the test set to evaluate on. Refer to App. F for more details.

Experimental details. On SynthBio, we generate a short biography for each entity in the test set using GPT-3.5-4K and GPT-4-8K, and we evaluate against reference texts using BLEU (Papineni et al., 2002) and BERTScore F1 (Zhang et al., 2020). We consider both zero- and 2-shot learning. See App. F.2.1 for the prompts and example generations. On Rotowire, we explore both GPT-3.5-16K and GPT-4-32K (the longer context windows are needed due to the length of the JSON), and evaluate against reference texts using using BLEU and ROUGE (Lin, 2004). See App. F.2.2 for the Rotowire prompts and example outputs.

Results. Our results are shown in the respective tables for each dataset (SynthBio, Tab. 1; Rotowire, Tab. 2). The results for data-to-text generation are generally positive. For SynthBio, in the few-shot case, we find that both symbolic generation strategies we considered yield comparable or superior performance to the baseline.⁵ Interestingly, in the zero-shot GPT-3.5-4K case, direct symbolic generation underperforms the baseline, though this gap is bridged via in-context learning. This could sug-

			BLEU	ROUL	ER	GER
GPT-3.5-16K	0-shot	Baseline Direct	$5.87 \\ 5.07$	$\begin{array}{c} 19.52\\ 19.14 \end{array}$	$0.00 \\ 4.00$	$0.00 \\ 0.00$
GPT-3.	1-shot	Baseline Direct	$\begin{array}{c} 12.26\\ 9.10\end{array}$	$22.66 \\ 20.65$	$\begin{array}{c} 0.00\\ 0.00\end{array}$	$0.00 \\ 0.00$
GPT-4-32K	0-shot	Baseline Direct Indirect	$4.94 \\ 2.24 \\ 4.66$	19.91 17.88 19.61	$0.00 \\ 0.00 \\ 0.00$	$0.00 \\ 0.00 \\ 0.00$
GPT-	1-shot	Baseline Direct Indirect	9.11 7.02 8.29	22.16 21.78 21.33	$0.00 \\ 0.00 \\ 2.00$	$0.00 \\ 0.00 \\ 2.00$

Table 2: Results on the Rotowire (Wiseman et al., 2017) dataset. We report the BLEU (Papineni et al., 2002) and ROUGE (ROU.-1, ROU.-2, ROU.-L; Lin, 2004) of the generated answers against the reference generations in the dataset. We also report the regular (ER (%)) and global (GER (%)) error rates. See §3.1 for a discussion.

gest that biographical generation in symbolic space is slightly harder than regular (non-symbolic) generation for GPT-3.5-4K. 254

For Rotowire, we find that the quality of symbolic generation generally trails the baseline, though this difference is smaller when using GPT-4-32K and indirect generation. Interestingly, GPT-3.5-16K seems to outperform GPT-4-32K in this task, as evidenced by comparing the baseline results under each model, which suggests that better performance may be obtained by modifying the indirect strategy so that GPT-3.5-16K is used to generate summaries in regular prose and GPT-4-32K is used to rewrite them using symbolic references.

In many cases, we find that poor symbolic generations arise from rendering errors. To this end, we also report the percentage of outputs whose symbolic form has at least one error (a specific reference in a response failed to render locally and was instead rendered as "undefined"; ER (%) and with at least one global error (where the Jinja parser simply failed to run, causing the whole response to fail and be replaced with "The text is not available."; GER (%)). We find that (i) GPT-3.5 tends to commit more errors than GPT-4 and (ii) providing few-shot examples tends to reduce errors, both of which are expected, though we also find that the indirect SymGen strategy leads to more errors than the direct strategy. We believe this to be because adapting regular, non-symbolic text to have symbolic references can sometimes be hard if the JSON is incomplete or the original text is not written in a

226

⁵For comparison, TempLM (Zhang et al., 2022)—which finetunes a pretrained LLM on the full training set—attains 40.30 BLEU and 54.30 in BERTScore, which are comparable to our GPT-4 results.

295

way that is amenable to the insertion of references.

Occasionally, we have also found errors that are unrelated to rendering errors. For example, for one case in Rotowire, the generation failed to recognize it needed to use addition, listing the second quarter points for the half time score instead of the sum of the first and second quarter (Fig. 8A; App. E). We also found an instance of the model incorrectly incrementing the winning team's game win count when reporting on a game, despite the win count reflecting the result of the game (Fig. 8B; App. E). In these instances, the model likely misunderstood the meaning of the field in question. However, in all of these cases, it is worth noting that SymGen makes it easier to *diagnose* such issues.

3.2 Counterfactual text generation

There is evidence that LLMs are capable of memorizing their training data (Carlini et al., 2019, 2023) and that this leads to their struggling to generate *counterfactual* data that goes against their learnt priors (Hernandez et al., 2023). In this section, we explore whether SymGen can lead to faithful generations when some of the conditioning data is counterfactual in nature.

Dataset. We collect a dataset comprised of 167 famous scientists who lived between 1800 CE and 311 2000 CE (e.g., Albert Einstein, Carl Sagan, Louis 312 313 Pasteur, etc.) and further generate *counterfactual* variants of each entity. The counterfactual variant 314 is designed to test for the extent to which an LLM 315 may ignore data that contradicts the information an LLM has seen during training, which has been noted to be a common failure mode of smaller language models (Hernandez et al., 2023). For more 319 details refer to App. F.

Experimental setup. We use GPT-3.5-4K to gen-321 erate obituaries for each of these (possibly coun-323 terfactual) entities. For the few-shot experiments, we provide two examples (see App. F.2.3 for our prompts and some example generations). Unlike SynthBio, we have no reference biographies for these entities, so we devise a new evaluation pro-327 cedure that tries to measure the factuality of the summaries. Specifically, we wrote questions for 329 each property in the schema of the data, and then prompted GPT-3.5-4K to answer them using only 331 the rendered text (see App. A for details). If the 332 answer was not present in the text, we asked the 333 model to answer with "Unknown." (the percentage of questions answered in this way is reported

by the unknown rate; UR (%)). We then computed both exact match accuracy and ROUGE of the provided responses against the response specified in the JSON; we include the latter as it is provides more leeway in the exact phrasing of the response than the exact match metric.

381

Results. The counterfactual obituary results are shown in Tab. 3. We find that in the zero-shot case, SymGen slightly outperforms our baseline, whereas in the few-shot case we find that it slightly underperforms the baseline. However, when we condition on whether the model gave a response versus stating it did not know the answer (Tab. 9), we find that performance is further improved in the zero-shot case and comparable in the few-shot setting. One possible explanation for this is that symbolic generation includes slightly less information than regular generation (especially in the few-shot case, as seen by the higher unknown rate), which in turn leads to more incorrect answers, since more questions were left unanswered. That is, SymGen seems to favor precision at the expense of recall, which may be desirable in some applications.

3.3 Question answering over structured data Another possible application of symbolically grounded generation is to enhance verifiability in question-answering (QA) over structured data. This is especially motivated by recent work on toolaugmented LLMs (Schick et al., 2023; Karpas et al., 2022), which are able to condition their generation on the results of API calls, which are often given in a structured format.

Dataset. To evaluate this setting, we construct a dataset of 32 finance-related questions about particular companies (e.g., "How does the book value of NFLX compare to that of ASML?"), coupled with company information from the AlphaVantage company overview API endpoint.⁶ Details about the questions and postprocessing are shown in App. B.

Experimental setup. We prompt the LLMs to answer finance-related questions given some company information. To evaluate the answers, we had one of the authors annotate each answer as acceptable or not; in general, an answer was deemed acceptable if the final answer was correct (see App. B for more details). We considered two LLMs: GPT-3.5-16K and GPT-4-32K, due to the length of the JSON data. Our prompts and some example out-

puts are given in App. F.3.1; we used three-shot prompting for the in-context learning setting.

Results. For the financial dataset, we report the percentage of responses judged as acceptable under each approach in Tab. 4. The results suggest that GPT-3.5-16K is unsuited for symbolic generation on this task, falling substantially short of the baseline. On the other hand, for GPT-4 all models offer reasonably comparable performance across generation strategies. See App. E for a qualitative analysis of some errors.

3.4 Reasoning

Besides providing symbolic references to fields in the source data, SymGen can also be used to express *symbolic computations* over the variables, e.g., computing the half-time points of a basketball game based on the first two quarter scores (Fig. 2).
By chaining a series of such operations, it opens up the possibility of interleaving arithmetic operations within language-based chain-of-thought reasoning. We explore this capability more formally in the context of solving arithmetic word problems.

Experimental setup. Fig. 3 illustrates one ap-proach for performing reasoning via symbolic gen-eration for a math problem in GSM8K (Cobbe et al., 2021). Each generated computation step is coupled with an assignment statement in Jinja, which re-lates the natural language explanation of the com-putation with a symbolic expression. Compared to chain-of-thought reasoning (CoT; Wei et al., 2022), explicit use of symbolic computations should lead

Table 5: Comparison of SymGen reasoning with other reasoning methods on GSM8K and GSM-hard; all approaches were evaluated using GPT-4-8K. Refer to §3.4 for a discussion.

to more easily verifiable computational results of each step; compared to program-aided language models (PAL; Gao et al., 2022) and program of thoughts prompting (PoT; Chen et al., 2023), which recast problems into an program and executes it to obtain a response, SymGen relies more on natural language as a scaffold, embedding symbolic computation within regular text.

Dataset. We compare the direct SymGen strategy against CoT and PAL on two datasets: GSM8K (Cobbe et al., 2021) and GSM-hard (Gao et al., 2022). GSM8K are grade school math problems like the one illustrated in Fig. 3 that typically require multiple steps of reasoning to solve. To create a more challenging testbed for LLMs, Gao et al. (2022) construct GSM-hard by replacing, for each problem in GSM8K, a randomly selected number with a large random number of up to seven digits. We use a random subset of 200 problems in the test set of GSM8K and GSM-hard for evaluation, as recent work find that it yields similar results to testing on the full 1.3K test set (Wang et al., 2023b).

Results. Tab. 5 compares the performance on GSM8K and GSM-hard using CoT, PAL, and our approach with GPT-3.5-4K and GPT-4-8K. Notably, it seems symbolic reasoning might not be necessary for GSM8K, since both our method and PAL perform similarly to CoT. However, when the computations are more complex as in GSM-hard, symbolic generation outperforms CoT by a clear margin when using both GPT-4-8K and GPT-3.5-4K. Our method slightly underperforms PAL

1 PROBLEM DESCRIPTION

At the trip to the county-level scavenger hunt competition, 90 people were required to split into groups for the competition to begin. To break people up into smaller groups with different leaders, 9-person groups were formed. If 3/5 of the number of groups each had mer bring back 2 seashells each, how many seashells did they bring?

2 SYMBOLIC GENERATION

There were 90 people (% set total_people = 90 %) and they were split into 9-person aroups % set group_size = 9 紛). So there were {% set total_groups = total_people/group_size %} groups. If 3/5 of the groups each had members bring back 2 seashells each, then {% set seashell_groups = total_groups*3/5 %} groups brought back seashells. Each group brought back 2 seashells per person {% set seashells_per_person = 2 %}, so they brought back seashells

3 RENDERED TEX^{*}

There were 90 people and they were split into 9-person groups. So there were 10 groups. If 3/5 of the groups each had members bring back 2 seashells each, then 6.0 groups brought back seashells. Each group brought back 2 seashells per person,

Figure 3: Illustration of SymGen reasoning on GSM8K, on an example generated by GPT-4. Given a math question (1), the LLM answers via direct symbolic generation, creating variables as needed (2), which can be rendered in a user-friendly manner (3). The syntax we use (Jinja) allows the creation of variables based on the source text (e.g., setting total_people to 90, (A), and performing computation by referencing existing variables (e.g., calculating total_groups based on total_people and group_size, **B**). We can moreover explain how a computation step relates to previous ones (C).

on GPT-4-8K, with the margin being larger using GPT-3.5-4K. This is somewhat expected, given that PAL is explicitly geared towards solving such arithmetic problems and moreover makes use of richer programming elements. Inspecting our method's failures on this dataset, we found that many errors arose from sensible (but incorrect) attempts to reason symbolically about a math problem using Jinja notation. See App. E for an error analysis.

In addition to our quality-focused empirical evaluation in §3, we also conduct a human study to ascertain whether the annotations enabled by Sym-Gen actually aid users in verifying LLM generations. We use Rotowire since it is a challenging testbed for verification: summaries contain many numbers referring to an array of fields, and slight errors might be hard to spot.

Annotation data. We picked five SymGen-465 generated (Indirect, GPT-4-32K) summaries of dif-466

ferent games in the Rotowire dataset and manually verified them for correctness. We then generated three version of each document that were inconsistent with the data by picking a random symbolic reference and replacing it with another symbolic reference with a different value that was within 2 units of the original value of the field. We prevent the resulting value from being nonsensical, e.g., by restricting percentages to still be within 0 and 100. For each of these four documents, we created two versions: a version with annotations, and one without any annotations (i.e., as if it were generated by a regular LLM).

Survey overview. We ask annotators to annotate four summaries: two of them contain SymGen annotations, allowing them to inspect the provenance of different numbers in the text when hovering over a number using their cursor, and two containing no annotations (i.e., the output of a regular LLM). Each summary is equally likely to come from a pool of correct or incorrect summaries, and the first step of each annotation is for the participant to determine whether the summary is correct (i.e., there are no inconsistencies between the summary and the source table) or incorrect (i.e., there is an inconsistency between the summary and the table). Crucially, this first step is timed. Answering this question reveals two more questions, asking the annotators to rate their confidence in their answer, and how easy it was for them to reach a decision, on a Likert scale. We ask these questions in order to measure whether SymGen annotations meaningfully impact (i) human accuracy at finding errors and (ii) how easy it is to verify a summary, where both objective ease (i.e., how long did it take to reach a decision) and subjective ease (i.e., how hard did it *feel* to go through and verify the text). At the end of the study, annotators are provided an exit survey were they are asked to rate whether they prefer annotations (over no annotations) with respect to both (i) the confidence in their decisions and (ii) their ease in reaching a decision. We also reward annotators for each question answered correctly to ensure that they are spending adequate effort on the task. More details on the study design, exact questions, and interface are given in App. D.

Enrollment. We recruited 60 annotators for the study via Prolific. See App. D for more details, including selection criteria, quality filters, etc.

Results. The per-annotation results for the study are shown in Tab. 6. We find that annotators

	Acc.	Time	Conf.	Effort
SymGen		1.98	4.63	4.14
Baseline	80.00	2.50	4.44	3.63

Table 6: Results of the human study, comparing a system with SymGen annotations to one without. We report accuracy (Acc.), time taken to determine if an example is correct in minutes (Time), and perceived confidence (Conf.) and effort (Effort) on a Likert scale (i.e., 1–5). For Conf. and Effort, higher scores indicate more confidence and less effort respectively. See §4 for details.

were equally likely to identify errors regardless of 518 whether SymGen annotations were shown. How-519 ever, when annotations were displayed, they took on average 20% less time to reach a decision about 521 whether an error was present or not. This makes 522 sense, since the annotations do not change whether the text is correct or not, they should only facilitate 524 the process of verifying it. We further find that 525 annotators feel slightly more confident of their final answers when using our approach and perceive 527 the verification task to be easier. Finally, from exit survey, we have that 71.67% of participants agree that annotations made them more confident in their 530 answers, and 83.33% agree that annotations made 531 the verification task easier. In all, the results suggest that SymGen annotations enable a faster and more pleasant verification experience, with some 534 annotators reporting "The annotations help tremendously", "[t]he annotations were nice and definitely 536 helped", and "[...] I could still compare the data without annotations it just took longer to find each piece of data". 539

Data-to-text generation. Classic approaches for the data-to-text problem used handcrafted templates to generate output sentences that interleave text with placeholder tokens which refer to relevant data fields (Kukich, 1983; McKeown, 1992; McRoy et al., 2000). Carefully engineered templates can provide strict guarantees against hallucinations, but require much manual work to specify, are domain-specific, and may sound robotic.

Data-driven methods for data-to-text initially focused on inducing templates from data (Liang et al., 2009; Angeli et al., 2010; Howald et al., 2013; Konstas and Lapata, 2013) which could be pipelined with a separate generation module. More recent approaches take advantage of large-scale datasets (Wiseman et al., 2017; Parikh et al., 2020) to learn end-to-end neural networks (Wang, 2019; Li and Wan, 2018; Yin and Wan, 2022). (See Sharma et al. (2022) for a recent survey). Of particular note are methods that use template-like structures within neural generative modules to separate out the "what to say" from the "how to say it" (Wiseman et al., 2018; Ye et al., 2020; Li and Rush, 2020; Wang et al., 2021; Puduppully et al., 2022; Zhang et al., 2022). These methods typically still require a sizable training set (generally on the order of hundreds or thousands), in contrast to the zero- and few-shot settings considered in the present work. 559

Tool-augmented LLMs. Recent work has augmented LLMs with tools/APIs to enhance their capabilities (Schick et al., 2023; Paranjape et al., 2023; Liang et al., 2023; Shen et al., 2023; Khot et al., 2023; Qin et al., 2023; Lu et al., 2023). These methods enable LLMs to generate string representations of API calls whose results are fed back in as additional context. Our method can be viewed as using a templating language as a tool. Whereas this line of work is usually concerned with enhancing LLM capabilities via external modules, our work instead focuses on using structured data as "tools" to improve verifiability. Our use of arithmetic computations within generations is also closely related to works that generate code snippets along with text to combine the benefits of symbolic computations and language-based reasoning (Gao et al., 2022; Chen et al., 2023; Zhang et al., 2023).

LLM verification. LLM verification is an orthogonal improvement to the reliability of LLMs, where the output of an LLM is automatically verified. Yue et al. (2023) and Gao et al. (2023) take an LLM generated response and a reference document it cites and use a separate module to determine whether the output of the LLM is entailed from the reference document. Verify-and-edit (Zhao et al., 2023) uses self-consistency checks to discover potential mistakes, and corrects those mistakes with knowledge retrieval. Poesia et al. (2023) allow an LLM to call a logical backend as a tool, so that it can perform logically sound and certifiable deductive reasoning.

6 Conclusion

In this paper, we propose symbolically grounded generation (SymGen) as a simple approach to text generation that yields more verifiable text, by effectively linking portions of the output to the provided input data. Our evaluation suggests that symbolic generation does not substantially reduce the overall quality of the text, all the while it increases the verifiability of an LLM's generations.

609 Limitations

This paper intends to demonstrate the utility po-610 tential of a simple method. As such, it focuses on 611 a broad evaluation rather than a deep and narrow one. We also do not perform a wide ablation of 613 614 the many possible ways of imbuing an LLM with the ability to generate symbolic references. We 615 considered only Jinja-style symbolic generation because it was flexible enough to be integrated into normal text and presumably prevalent enough in 618 619 the training corpus to perform well. Future work could more thoroughly evaluate what other templating languages these LLMs have the capacity 621 to do this for. Finally, our work most focuses on settings with readily available structured data that 623 is pertinent to model generation. The GSM experiments serve as a preliminary exploration of the 625 case when such structured data is not available, and future work could try to extend our method by 627 either automatically generating structured data or retrieving relevant data. Furthermore, as we saw in §3.1 for SynthBio, even when data is available, if it is not high quality, SymGen might yield text with 631 grammatical and typographical errors.

Properties and questions. Tab. 7 lists the Wikidata properties we include in our entities alongside the questions we corresponding question we provide the LLM in the QA evaluation.

Evaluation prompt. Refer to App. F.3 for the prompt we use in our QA evaluation of generated obituaries.

B Financial QA human evaluation

We had a total of 32 questions in the financial QA evaluation; the questions are shown in Tab. 8. There are two types of question: pairwise-comparison questions (pair) and multiway-comparison questions (multi). For the pairwise comparison questions, we only include information from the two companies in question. For the multiway-comparison questions we show data from seven tickers: ORCL, ASML, TSLA, GOOG, CRM, AVGO, NFLX.

The specific structured input provided is the result the company overview endpoint from the Alpha-Vantage API.⁷ We applied some minor postprocessing to the API response to ensure that all fields that are numerical in nature (e.g., SharesOutstanding, MarketCapitalization) are actually numerical (i.e., integers or floats) in the JSON as opposed to strings. Note that all questions are answerable from the

⁷An example is shown here: https://www.alphavantage.co/query?function=OVERVIEW&symbol=IBM&apikey=demo.

Y acoulon	0040

Question

Question code	Question
pair_market-cap	Which company has the largest market capitalization, GOOG or ASML?
pair_market-cap	Which company has the largest market capitalization, ASML or ORCL?
pair_market-cap	Which company has the largest market capitalization, TSLA or CRM?
pair_pe-ratio	How do the P/E ratios of NFLX and ASML compare?
pair_pe-ratio	How do the P/E ratios of GOOG and CRM compare?
pair_pe-ratio	How do the P/E ratios of NFLX and AVGO compare?
multi_dividend	Which company has a higher dividend yield?
multi_revenue-mult	Which company has a higher revenue multiple?
pair_book-value	How does the book value of NFLX compare to that of ASML?
pair_book-value	How does the book value of ORCL compare to that of NFLX?
pair_book-value	How does the book value of CRM compare to that of TSLA?
multi_growth-yoy	Which company grew the fastest YoY in the most recent quarter?
pair_operating-margin	How do the operating margins of GOOG and CRM compare?
pair_operating-margin	How do the operating margins of NFLX and CRM compare?
pair_operating-margin	How do the operating margins of AVGO and TSLA compare?
multi_return-assets	Which company has a higher return on assets (TTM)?
pair_eps	How does the EPS (earnings per share) of ASML compare to AVGO?
pair_eps	How does the EPS (earnings per share) of TSLA compare to ORCL?
pair_eps	How does the EPS (earnings per share) of CRM compare to GOOG?
pair_beta	What are the respective market betas for CRM and GOOG?
pair_beta	What are the respective market betas for GOOG and NFLX?
pair_beta	What are the respective market betas for NFLX and AVGO?
pair_50d-avg	How do the 50-d moving averages between AVGO and GOOG compare?
pair_50d-avg	How do the 50-d moving averages between TSLA and ORCL compare?
pair_50d-avg	How do the 50-d moving averages between ORCL and GOOG compare?
pair_forward-pe-ratio	What's the difference in the forward P/E ratio between ASML and NFLX?
pair_forward-pe-ratio	What's the difference in the forward P/E ratio between AVGO and ASML?
pair_forward-pe-ratio	What's the difference in the forward P/E ratio between CRM and NFLX?
multi_quart-growth	Which company has a stronger quarterly earnings growth (YoY)?
pair_ebitda	How do ORCL and GOOG's EBITDA multiples compare?
pair_ebitda	How do ASML and TSLA's EBITDA multiples compare?
pair_ebitda	How do ASML and GOOG's EBITDA multiples compare?

Table 8: The 32 questions that were considered for the financial QA evaluation.

		C-EM (%)	C-ROU1	C-ROU2	C-ROUL
0-shot	Baseline Direct	$80.35 \\ 84.07$	$87.56 \\ 89.59$	$\begin{array}{c} 62.55\\ 63.09 \end{array}$	$87.50 \\ 89.57$

Table 9: GPT-3.5-4K results of the automated question–answering evaluation on the obituary dataset, when we condition of the model not having abstained from giving an answer, i.e., when the answer given by the model was not "Unknown." We report the conditioned exact match accuracy (C-EM (%)) and ROUGE (C-ROU.-1, C-ROU.-2, C-ROU.-L; Lin, 2004) of the inferred answers from the generated text against the corresponding true answers given by the source data. Refer to §3.2 for a discussion.

data provided data (e.g., there is a field MarketCapitalization in the structured data that allows the pair_market-cap questions to be answered).

To evaluate the generations, we had one of the authors in the paper annotate each of the responses according to whether the answer was acceptable or not. We adopted a loose criteria for acceptability:

- 1. If the question had an objective answer (e.g., the answer to "Which company has a largest market capitalization, GOOG os ASML?" is ultimately either GOOG or ASML) then the generation was acceptable as long as the final answer given by the question was acceptable. Note that if the *reasoning* given for the answer was incorrect but the final answer was correct, the answer was still treated as acceptable. This choice is deliberate, since in certain cases it can be hard to gauge whether the reasoning is correct despite the answer being correct. To reduce subjectivity as much as possible, we adopted the loosest possible interpretation of acceptability for questions with objective answers.
- 2. If the answer did not have an objective answer (e.g., there are multiple sensible answers to "How do ORCL and GOOG's EBIDTA multiples compare?"), then we deem an answer acceptable if the reasoning in the answer is sensible and correct.
- 3. If the model failed to generate an answer (e.g., rendering error, or did not answer the question) then the answer was not acceptable.

C Conditioned obituary results

In Tab. 9, we include the results on the obituary dataset when we condition on the QA model not having abstained from answering.

D Details on human study

We include further details on the human study below.

D.1 Detailed breakdown of summary steps

The following are the different pages the annotators see:

- 1. **Instruction page**: They first see a page that gives them an overview of the study and the interface, a description of the questions they will answer, the structure of the study (with the approximate times to complete each section, alongside information about compensation), and a section with further notes. We make it clear here that they are being timed, and that the first three annotations will be practice examples and the next four are the actual examples they need to annotate. For simplicity, we use System A to refer to generations without annotations, and System B to refer to the system with annotations.
- Practice round 1: Gives an example of a document without annotations and without errors. Specifically, we say: "The following example, which could have been generated by system A, contains

nothing that directly contradicts the table on the left (we have checked it ourselves by going through 924 the different numbers mentioned in the text, but you will have to do it yourself for future examples). 925 For this reason, you should say that the text is consistent with the source data below (this is an 926 attention check). For these practice questions, it doesn't matter what you write down for confidence 927 and ease, but after the practice rounds are finished, you should start answering those." 928 3. **Practice round 2**: Gives an example document without annotation but with an error. Specifically, 929 we say: "The following is an example, that also could have been generated by System A, is identical 930 except that it now contains an error. Specifically, the text says that number of rebounds by Andrew 931 Bogut made was 7, but the number in the table says it is actually 6 (you have to scroll down the table 932 to see Andrew Boguts's statistics). For this reason, you should state that the text is inconsistent with 933 the source data below (this is an attention check). Again, since this is a practice question, it doesn't 934 matter what you answer for your confidence and ease of finding the answer." 935 4. **Practice round 3**: Gives an example of a document with annotations, and with an error. Specifically, 936 we say: "The example shown below, which illustrates system B's annotations, is very similar but also 937 contains an error: The text says that the number of rebounds that Stephen Curry made 38 points, but 938 in reality he scored 37 points. If you hover your cursor over the number 38, a tooltip will show up, 939 showing that the 38 actually refers to the Golden State Warrior's 3Pt Field Goal Percentage. For this 940 reason, you should state that the text is inconsistent with the source data below (this is an attention 941 check). Again, since this is a practice run, it doesn't matter what you answer for your confidence and 942 ease of finding the answer, but you should start answering them properly from now on." 943 5. Annotation 1: First example they need to annotate. 944 6. Annotation 2: Second example they need to annotate. 945 7. Annotation 3: Third example they need to annotate. 946 8. Annotation 4: Fourth example they need to annotate. 947 **Quality checks.** We request a participant return their submission if they get two of the practice rounds 948 wrong. In our opinion, our instructions for those rounds are clear as to what they should do (i.e., they give 949 the correct answer), so participants that are reading the instructions should get these correct. If they get 950 only one wrong, we allow them to complete the study and compensate them as other participants, but do 951 not use their results in our analysis. 952 **Sampling of annotations.** When the user passes the practice round, we show them four documents to 953 annotate. Our sampling process obeys the following properties: 954 1. Each of the underlying documents is unique (i.e., we pick 4 out of the 5 documents to show the 955 annotator) 956 2. Exactly 2 of the documents are shown with annotations, and two are shown without annotations. 957 These may appear in any order. 958 3. Each document has a 50% chance of being consistent with the text. If a document is sampled to 959 be inconsistent, then we sample one of the three possible incorrect variants to show, uniformly at 960 random. 961 **D.2 Ouestions asked to annotators** 962 For each document, the annotators are asked: 963 1. Is the text consistent or inconsistent with the source data? 964 · Possible answers: Consistent or Inconsistent 965

966 967	• Note: Answering this question stops a timer that begins running when the page is loaded. This is the annotation time we report.
968	2. How confident are you in your answer? [1 means least confidence (completely unsure), 5 means
969	most confidence (absolutely certain)]
970	• Possible answers: 1, 2, 3, 4, 5
971	3. How easy was it reach your decision? [1 is hardest, 5 is easiest]
972	• Possible answers: 1, 2, 3, 4, 5
973 974	After annotating all documents, the exit survey asked them "Please rate the degree to which you agree with the following statement:"
975 976	1. System B (i.e., with annotations) gave me more confidence in my answers that System A (i.e., no annotations).
977	• Possible answers: Strongly disagree, Disagree, Neutral, Agree, Strongly agree
978 979	2. System B (i.e., with annotations) made it easier for me to do the task than System A (i.e., no annotations).
980	• Possible answers: Strongly disagree, Disagree, Neutral, Agree, Strongly agree
981 982	And finally there we added "Optionally, you can leave some comments about the study below." alongside a textbox for comments.
983	D.3 Interface
984	The following images illustrate the annotation interface:
985	1. Fig. 4 depicts the instruction page shown to each annotator.
986	2. Fig. 5 illustrates the full annotation interface for a document, after it has been filled out.
987	3. Fig. 6 illustrates the the exit survey, after it has been filled out.
988 989 990 991	4. Fig. 7 illustrates how the interface changes when you hover over an annotation with your cursor. Specifically, a tooltip appears (describing the provenance for the field) and the respective field gets highlighted on the left. The tooltips and the table are both human readable (the values are manually written based on the schema of the data, which is known).
992	E Qualitative error analysis
993 994	Fig. 8 shows some example errors in SymGen generations. Below we include further qualitative comments on the errors produced by the systems we analysed.

GSM error anlaysis. We inspected GPT-3.5-4K failures by our model. In one case the model generates
{% set initial_marbles = 'x' %}, in an attempt to effectively create a variable, as one would do
when reasoning about a problem algebraically. In another case, the statement {% set red_paint =
white_paint = purple_paint %} was generated in response to "There are equal amounts of red, white,
and purple paint in the mural," which is incorrect Jinja despite making sense conceptually.

Financial error analysis. During our analysis, we found that GPT-3.5-16K struggled with CoT-like (Wei 1000 et al., 2022) behavior in symbolic form, e.g., when it required comparing a set of numbers and determining 1001 the largest one, it would generate references to the numbers involved in the comparison (as is standard 1002 with CoT), but it would not determine the largest one correctly (e.g., Fig. 8C). We also found evidence 1003 of the models struggling with plausible but syntactically incorrect Jinja generations. In fact, most errors 1004 in the symbolic form of the output were because of incorrectly referencing one particular variable, 1005 viz., 50DayMovingAverage (e.g., Fig. 8D). This suggests that techniques for constrained decoding with 1006 LLMs (Shin et al., 2021; Scholak et al., 2021; Poesia et al., 2022, 2023; Wang et al., 2023a) could be 1007 employed to curtail syntax errors. 1008

F Experimental details

Unless otherwise specified, we run all experiments using the Azure API and use the model version 0613. 1010 We state the specific version of the model we use in the main text. We use the SacreBLEU, ROUGE and 1011

Figure 7: Effect of hovering over an annotation in a document that has annotations. A tooltip shows up containing a short description of the field, and the corresponding entry in the table is highlighted.

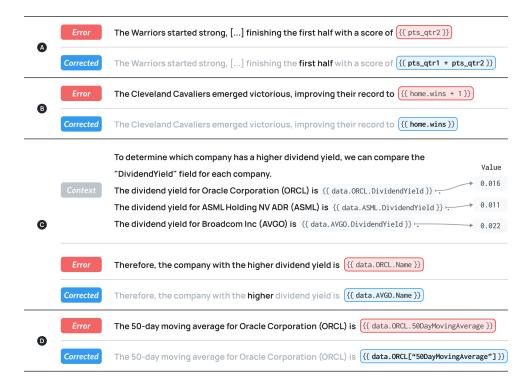

Figure 8: SymGen makes the identification of hallucinations easier. In A SymGen makes an error (indicated with dark red background) when the model needs to add up two values; in **B**, the model incorrectly increments the values by one. In **O** the model generates a correct chain-of-thought, but fails, likely because the symbolic references make it harder to check which value is actually highest. Finally, in **D**, we see a sensible but syntactically incorrect Jinja expression, which causes the whole generation to become unrenderable. Note how even when there are errors, symbolic generation provides a glimpse into the models' internal reasoning, making it easier to understand the motive for such errors (e.g., generating +1 in **B**).

Table 10: Comparison of the four datasets we consider in our study. We note the domain of the dataset (Domain), the number of datapoints we evaluate on (Eval #), the types of the fields of the data, the average number of fields in each example's data (Field #), and whether there is a reference generation for each datapoint in the dataset (Ref?).

take each entity's attribute and progressively corrupt a subset of its properties,¹⁰ by sampling a different value from the empirical distribution of that property's values from the collected data. For each entity, we create copies that have 50% and 100% of the selected properties corrupted.

We then constructed a dictionary for each entity containing a value for each one of 27 manually selected 1032 Wikidata properties, e.g., country of citizenship, place of birth, etc. (see App. A for a complete listing). If 1033 an entity did not possess such a property in its Wikidata page, we do not add it to the entity's dictionary; 1034 if the entity possessed multiple values associated with that property, we selected the first one that was 1035 returned by the Wikidata API. This results in one dictionary of property-value attributes for each scientist. To construct the counterfactual variants of each entity, we take each entity's dictionary and progressively 1037 corrupt a subset of its properties,¹¹ by sampling a different value from the empirical distribution of that 1038 property's values from the collected data. For each entity, we create copies that have 50% and 100% of 1039 the selected properties corrupted. All of these are added back to obtain the final dataset.

F.2 Prompts

We provide the prompts we use in the sections below.

F.2.1 SynthBio prompts

```
SynthBio prompt (Baseline)
```

System prompt:

Your task is to write a biography about a person whose description is given in JSON. You must mention and be faithful about every property of the person in your biography.

Few shot examples (optional):

```

LLM generates Synthbio summary without symbolic references.

EXAMPLE OUTPUT (GPT-4-8K)

Helmut Kaiser was a renowned German philosopher and theologian, born on August 17, 1863, in Nuremberg, Germany. He completed his Ph.D. in Philosoph from the Philosophical University of Erlangen-Nuemberg in 1886. His most notable work was "Philosophical Problems of Theism". He was awarded the Honorary Member of the Lutheran Liturgical Institute at the University of Chicago and received the University Grant of the City of Frankfurt am Main in 1911. He was married to Frieda Schoenlein and they had five children: Rudolf, Kurt, Gertraud, Marianne, and Rosemarie. Kaiser passed away from heart disease and artery sclerosis on October 17, 1947, in Frankfurt am Main, Germany, where he was also laid to rest.

SynthBio prompt (Direct)

System prompt:

Your task is to write a biography about a person whose description is given in JSON. You must mention and be faithful about every property of the person in your biography.

Instead of responding directly with the text, you must generate Jinja-style expressions in the text with references to fields in the provided JSON, e.g., given JSON that says:

```
```json
{
 "data": {
 "place_of_birth": "Ohio"
 }
}
```

- - -

then instead of generating "... was born in Ohio" you should generate "... was born in {{ data.place\_of\_birth }}". Note that you can only reference fields that exist in the JSON. The user will be displayed a version of this message that has the references filled in, and you should ALWAYS try to use such references instead of copying the text directly when possible.

```
Few shot examples (optional):
```

```

Write a summary of the game described above.

### Assistant:

The Miami Heat (7-6) took down the Orlando Magic (6-9) 99-92 on Saturday night at the Amway Center in Orlando. The Heat were just too much for the Magic when all was said and done, as they made a nice run in the fourth to get a seven-point win. What makes the win even more impressive is that Miami did it without guard Dwyane Wade (hamstring). The Heat got plenty of production from some key players to help get the job done though. They were led in scoring by Chris Bosh, who put up 32 points (13-20 FG, 4-6 3Pt, 2-2 FT) to go with 10 rebounds. Mario Chalmers had a huge night also, scoring 24 points (10-16 FG, 2-5 3Pt, 2-4 FT) to go with eight assists and five rebounds. Miami fans have to be happy to see rookie Shabazz Napier stepping up big, as he played extended minutes (28), and scored 12 points (4-8 FG, 2-5 3Pt, 2-4 FT) to go with two rebounds, two steals and one assist. Miami has a quick turnaround, as they take on the Charlotte Hornets at home Sunday night.

The Magic just couldn't get enough production to outscore the Heat on this night, as only three players hit double digits, with Nikola Vucevic having a monster night, scoring 33 points (12-24 FG, 9-11 FT), with 17 rebounds. Vucevic was just dominate, and grabbed 11 offensive boards on the night. The other production came from Victor Oladipo, who had 14 points (5-11 FG, 1-4 3Pt, 3-5 FT), with four rebounds, two assist and two steals, as well as Evan Fournier, who scored 11 points (5-15 FG, 1-5 3PT) with six assists and six rebounds. The Magic get a night off now, before taking on the Cleveland Cavaliers on Monday.

LLM generates game summary without symbolic references

#### EXAMPLE OUTPUT (GPT-4-32K)

The Atlanta Hawks (46-12) secured a victory against the Orlando Magic (19-41) with a final score of 95-88. The Hawks started strong with a 28-point first quarter and maintained their lead throughout the game, despite a slight dip in the second quarter. They managed to shoot 44% from the field and 45% from the three-point line. The Hawks also outrebounded the Magic 42-40 and had more assists (27-22).

The Hawks' top performers were Paul Millsap with 20 points, Al Horford with 17 points and 13 rebounds, and DeMarre Carroll with 15 points. Jeff Teague also contributed significantly with 17 points and 7 assists. On the other side, the Magic struggled with their free throws, making only 54% of them. However, they managed to shoot 45% from the field and 35% from beyond the arc. The Magic's standout player was Nikola Vucevic, who scored 21 points and grabbed 15 rebounds. Victor Oladipo also had a solid performance with 19 points, while Tobias Harris added 15 points.

Despite their efforts, the Magic couldn't overcome the Hawks' strong performance, resulting in their 41st loss of the season. The Hawks, on the other hand, continued their impressive run, securing their 46th win.

## **Rotowire prompt (Direct)**

### System prompt:

Your task is to write a summary of a basketball game whose statistics are given in JSON. You must remain faithful to the provided statistics in your summary.

Instead of responding directly with the text, you must generate Jinja-style expressions in the text with references to fields in the provided JSON, e.g., given JSON that says:

```
···json
{
 "data": {
 "place_of_birth": "Ohio"
}
```

then instead of generating "... was born in Ohio" you should generate "... was born in {{ data.place\_of\_birth }}". Note that you can only reference fields that exist in the JSON. The user will be displayed a version of this message that has the references filled in, and you should ALWAYS try to use such references instead of copying the text directly when possible.

Write a summary of the game described above.

### Assistant:

The Miami Heat (7-6) took down the Orlando Magic (6-9) 99-92 on Saturday night at the Amway Center in Orlando. The Heat were just too much for the Magic when all was said and done, as they made a nice run in the fourth to get a seven-point win. What makes the win even more impressive is that Miami did it without guard Dwyane Wade (hamstring). The Heat got plenty of production from some key players to help get the job done though. They were led in scoring by Chris Bosh, who put up 32 points (13-20 FG, 4-6 3Pt, 2-2 FT) to go with 10 rebounds. Mario Chalmers had a huge night also, scoring 24 points (10-16 FG, 2-5 3Pt, 2-4 FT) to go with eight assists and five rebounds. Miami fans have to be happy to see rookie Shabazz Napier stepping up big, as he played extended minutes (28), and scored 12 points (4-8 FG, 2-5 3Pt, 2-4 FT) to go with two rebounds, two steals and one assist. Miami has a quick turnaround, as they take on the Charlotte Hornets at home Sunday night. The Magic just couldn't get enough production to outscore the Heat on this night, as only three players hit double digits, with Nikola Vucevic having a monster night, scoring 33 points (12-24 FG, 9-11 FT), with 17 rebounds. Vucevic was just dominate, and grabbed 11 offensive boards on the night. The other production came from Victor Oladipo, who had 14 points (5-11 FG, 1-4 3Pt, 3-5 FT), with four rebounds, two assist and two steals, as well as Evan Fournier, who scored 11 points (5-15 FG, 1-5 3PT) with six assists and six rebounds. The Magic get a night off now, before taking on the Cleveland Cavaliers on Monday.

### User:

Your job is to now rewrite the answer you provided above, but instead of responding directly with the text, you must generate Jinja-style expressions in the text with references to fields in the provided JSON, e.g., given JSON that says:

```
```json
{
    "data": {
        "place_of_birth": "Ohio"
    }
}
```

then instead of generating "... was born in Ohio" you should generate "... was born in {{ data.place_of_birth }}". Note that you can only reference fields that exist in the JSON. The user will be displayed a version of this message that has the references filled in, and you should ALWAYS try to use such references instead of copying the text directly when possible. Remember, you MUST make sure you ONLY use fields that exist in the JSON. You must NOT make up fields.

EXAMPLE OUTPUT (GPT-4-32K)

The Atlanta Hawks (46-12) defeated the Orlando Magic (19-41) 95-88 at home. The Hawks had a strong performance in the third quarter, scoring 34 points, which helped them secure the victory. The Hawks were led by Paul Millsap, who scored 20 points, and Al Horford, who added 17 points and grabbed 13 rebounds. Jeff Teague also contributed with 17 points and 7 assists. On the other hand, the Magic were led by Nikola Vucevic, who had a strong performance with 21 points and 15 rebounds. Victor Oladipo also contributed with 19 points, while Tobias Harris added 15 points. Despite the loss, the Magic outperformed the Hawks in the second quarter, scoring 29 points.

       }
   }
```

Niels Henrik Abel, a renowned mathematician, passed away at the young age of 27 in Froland, Norway. Born in Nedstrand, Abel was a proud Norwegian citizen and a devoted Lutheran. He was educated at the University of Oslo, where he later worked as a professor. Abel made significant contributions to the field of calculus, most notably the concept of the abelian group. He was a member of the Royal Norwegian Society of Sciences and Letters and received the prestigious Grand prix des sciences mathematiques. Sadly, Abel's life was cut short due to tuberculosis. He will be remembered for his remarkable achievements and dedication to the world of mathematics.

Generate untemplated obituary. LLM generates obituary without symbolic references

EXAMPLE OUTPUT (GPT-3.5-4K)

Herbert Spencer, a distinguished writer and botanist, has passed away at the age of 83 in Brighton. Born in Derby to William George Spencer, he was a citizen of the United Kingdom of Great Britain and Ireland. Spencer made significant contributions to the field of botany and worked as a writer for The Economist. He was a member of the Athenaeum Club and was known for his notable work, "Social Statics." Spencer was a proponent of agnosticism and was fluent in English. Although not awarded, he was nominated for the Nobel Peace Prize. Spencer will be laid to rest at Highgate Cemetery, leaving behind a legacy of intellectual pursuits and contributions to the scientific community.

"ExDividendDate": "None"
```

LLM generates answer without symbolic references.

EXAMPLE OUTPUT (GPT-4-32K) The company with the largest market capitalization is Alphabet Inc Class C (GOOG) with a market capitalization of 1,536,753,926,000 USD.

Financial prompt (Direct)

System prompt:

Your task is to answer a finance-related question based on some company information given in JSON. You must remain remain faithful to the provided information in your answer.

Instead of responding directly with the text, you must generate Jinja-style expressions in the text with references to fields in the provided JSON, e.g., given JSON that says:

```json

```
{
 "data": {
 "place_of_birth": "Ohio"
 }
}
```

then instead of generating "... was born in Ohio" you should generate "... was born in {{ data.place\_of\_birth }}". Note that you can only reference fields that exist in the JSON. The user will be displayed a version of this message that has the references filled in, and you should ALWAYS try to use such references instead of copying the text directly when possible.

```

 "RevenuePerShareTTM": 52.56,
 "ProfitMargin": 0.0243,
 "OperatingMarginTTM": 0.0572,
"ReturnOnAssetsTTM": 0.0247,
 "ReturnOnEquityTTM": 0.0872,
 "RevenueTTM": 538046005000,
 "GrossProfitTTM": 225152000000,
"DilutedEPSTTM": 1.26,
 "QuarterlyEarningsGrowthYOY": -0.986,
 "QuarterlyRevenueGrowthYOY": 0.108,
 "AnalystTargetPrice": 160.61,
 "TrailingPE": 94.9,
 "ForwardPE": 43.86
 "PriceToSalesRatioTTM": 1.797,
 "PriceToBookRatio": 6.61,
 "EVToRevenue": 1.948,
"EVToEBITDA": 19.3,
 "Beta": 1.188,
"52WeekHigh": 145.86,
 "52WeekLow": 81.43,
 "50DayMovingAverage": 132.31,
 "200DayMovingAverage": 117.12
 "SharesOutstanding": 10317800000,
 "DividendDate": "None"
 "ExDividendDate": "None"
 'TSM": {
 "Symbol": "TSM",
 "AssetType": "Common Stock",
 . . .
```

```
"DividendDate": "2024-01-11",
"ExDividendDate": "2023-12-14"
}
}
```

}

The 50-day moving average for Amazon.com Inc (AMZN) is 132.31 USD, while for Taiwan Semiconductor Manufacturing (TSM) it is 90.20 USD. Therefore, AMZN's 50-day moving average is higher than TSM's.

# 👩 User:

Your job is to now rewrite the answer you provided above, but instead of responding directly with the text, you must generate Jinja-style expressions in the text with references to fields in the provided JSON, e.g., given JSON that says:

```
``json
{
 "data": {
 "place_of_birth": "Ohio"
 }
}
```

then instead of generating "... was born in Ohio" you should generate "... was born in {{ data.place\_of\_birth }}". Note that you can only reference fields that exist in the JSON. The user will be displayed a version of this message that has the references filled in, and you should ALWAYS try to use such references instead of copying the text directly when possible. Remember, you MUST make sure you ONLY use fields that exist in the JSON. You must NOT make up fields.

# Assistant:

```
The 50-day moving average for {{ data.AMZN.Name }} ({{ data.AMZN.Symbol }}) is
{{ data.AMZN['50DayMovingAverage'] }} USD, while for {{ data.TSM.Name }}
({{ data.TSM.Symbol }}) it is {{ data.TSM['50DayMovingAverage'] }} USD. Therefore,
{{ data.AMZN.Symbol }}'s 50-day moving average is higher than {{ data.TSM.Symbol }}'s.
```

# F.3.2 GSM8K prompts

**GSM8K prompt (Direct)** 

### System prompt:

You are a helpful assistant.

### Few shot examples (optional):

### 🧑 User:

We are working on solving a math question. We want to generate the computation steps in jinja templating format along the way. We allow using  $\{ \ ad \ \} \ to$  quote variables, and  $\{ \ set \ variable=value \ \} \ to$  set variables. We do NOT allow using setting unknown variables (e.g., X) to a value, and the computation should be as simple as possible. Let's do a practice round.

# Assistant:

Sounds great!

### User:

Question: There are 15 trees in the grove. Grove workers will plant trees in the grove today. After they are done, there will be 21 trees. How many trees did the grove workers plant today?

### Assistant:

```
There are 15 trees originally{% set initial_trees = 15 %}. Then there were 21 trees after some more were planted{% set final_trees = 21 %}. Therefore, there are {% set trees_planted = final_trees - initial_trees %}{{ trees_planted }} trees planted today. Answer: {{ trees_planted }}
```

## 👩 User:

Question: If there are 3 cars in the parking lot and 2 more cars arrive, how many cars are in the parking lot?

# Assistant:

```
There are originally 3 cars{% set initial_cars = 3 %}. 2 more cars arrive{% set arrived_cars = 2 %}.
The total car in the parking lot is
{% set final_cars = initial_cars + arrived_cars %}{{ final_cars }}.
Answer: {{ final_cars }}
```

# J User:

Question: Leah had 32 chocolates and her sister had 42. If they ate 35, how many pieces do they have left in total?

# Assistant:

```
Originally, Leah had 32 chocolates{% set leah_chocolates = 32 %}, and her sister had 42{% set sister_chocolates = 42 %}. In total, they had {% set total_chocolates = leah_chocolates + sister_chocolates %}{{ total_chocolates }}
```

chocolates. After eating 35{% set chocolates\_eaten = 35 %}, they had
{% set chocolates\_left = total\_chocolates - chocolates\_eaten %}{{ chocolates\_left }} left.
Answer: {{ chocolates\_left }}

# 🧑 User:

Question: Jason had 20 lollipops. He gave Denny some lollipops. Now Jason has 12 lollipops. How many lollipops did Jason give to Denny?

#### Assistant:

Jason started with 20 lollipops{% set initial\_lollipops = 20 %}. Then he had 12 after giving some to
Denny. Now Jason has 12 lollipops{% set final\_lollipops = 12 %}. So he gave Denny
{% set lollipops\_given = initial\_lollipops - final\_lollipops %}{{ lollipops\_given }}.
Answer: {{ lollipops\_given }}

### 👩 User:

Question: Shawn has five toys. For Christmas, he got two toys each from his mom and dad. How many toys does he have now?

# Assistant:

Shawn started with 5 toys{% set initial\_toys = 5 %}. He got 2 toys each from his mom and dad, that's
{% set new\_toys = 2 + 2 %}{{ new\_toys }} more toys. So he have
{% set toys\_now = initial\_toys + new\_toys %}{{ toys\_now }} toys.
Answer: {{ toys\_now }}

# 🧑 User:

Question: There were nine computers in the server room. Five more computers were installed each day, from monday to thursday. How many computers are now in the server room?

### Assistant:

There were originally 9 computers{% set initial\_computers = 9 %}. For monday to
thursday{% set days = 4 %}, 5 more computers were added{% set daily\_added\_computers = 5 %}.
Therefore, a total of {% set total\_added\_computers = daily\_added\_computers \* days %}{{
 total\_added\_computers }} is added. There are
{% set total\_computers = total\_added\_computers + initial\_computers %}{{ total\_computers }}
in the server room?

Answer: {{ total\_computers }}

#### 👩 User:

Question: Michael had 58 golf balls. On tuesday, he lost 23 golf balls. On wednesday, he lost 2 more. How many golf balls did he have at the end of wednesday?

#### Assistant:

```
Michael started with 58 golf balls{% set initial_golf_balls = 58 %}. After losing 23 on
tuesday{% set lost_tuesday = 23 %}, he had
{% set golf_balls_left = initial_golf_balls - lost_tuesday %}{{ golf_balls_left }}. He
lost 2 more on wednesday{% set lost_wednesday = 2 %}, so he has
{% set final_golf_balls = golf_balls_left - lost_wednesday %}{{ final_golf_balls }} golf
balls.
Answer: {{ final_golf_balls }}
```

### 👩 User:

Question: Olivia has \$23. She bought five bagels for \$3 each. How much money does she have left?

### Assistant:

```
Olivia had 23 dollars{% set initial_money = 23 %}. 5 bagels{% set bagel_count = 5 %} for 3 dollars
each{% set bagel_price = 3 %} will be
{% set bagel_cost = bagel_price * bagel_count %}{{ total_bagel_cost }} dollars. So she has
{% set money_left = initial_money - bagel_cost %}{{ money_left }} dollars.
Answer: {{ money_left }}
```

### User:

Question we want an answer for

# EXAMPLE INPUT

Here is another one: Question: Janet's ducks lay 16 eggs per day. She eats three for breakfast every morning and bakes muffins for her friends every day with four. She sells the remainder at the farmers' market daily for \$2 per fresh duck egg. How much in dollars does she make every day at the farmers' market?

# Assistant:

LLM generates answer with symbolic references

EXAMPLE OUTPUT (GPT-4-8K)

LAAMPLE OUTPOT (GF14-36K)
Janet's ducks lay 16 eggs per day(% set total\_eggs = 16 %). She eats 3 for breakfast{% set breakfast\_eggs = 3 %) and uses 4 for
muffins{% set muffin\_eggs = 4 %). So she uses {% set used\_eggs = breakfast\_eggs + muffin\_eggs %){{ used\_eggs }} eggs. The remainder is
{% set market\_eggs = total\_eggs - used\_eggs %}{{ market\_eggs }} eggs. She sells these at the farmers' market for \$2 per egg(% set egg\_price = 2 %),
so she makes {% set market\_income = market\_eggs \* egg\_price %}{{ market\_income }} dollars every day.
Answer: {{ market\_income }}
