

PUTNAM-AXIOM: A FUNCTIONAL & STATIC BENCHMARK FOR MEASURING HIGHER LEVEL MATHEMATICAL REASONING IN LLMs

Anonymous authors

Paper under double-blind review

ABSTRACT

As large language models (LLMs) continue to advance, many existing benchmarks designed to evaluate their reasoning capabilities are becoming saturated. Therefore, we present the Putnam-AXIOM Original benchmark consisting of 236 mathematical problems from the William Lowell Putnam Mathematical Competition, along with detailed step-by-step solutions. To preserve the Putnam-AXIOM benchmark’s validity and mitigate potential data contamination, we created the Putnam-AXIOM Variation benchmark with functional variations of 52 problems. By programmatically altering problem elements like variables and constants, we can generate unlimited novel, equally challenging problems not found online. We see that almost all models have significantly lower accuracy in the variations than the original problems. Our results reveal that OpenAI’s o1-preview, the best performing model, achieves merely 41.95% accuracy on the Putnam-AXIOM Original but experiences around a 30% reduction in accuracy on the variations’ dataset when compared to corresponding original problems. Moreover, we explore metrics beyond boxed accuracy to assess models on complex tasks like natural language theorem proving, crucial for evaluating reasoning capabilities in depth, opening the possibility for open-ended evaluation of reasoning strings. The data and the evaluation code are available at <https://anonymous.4open.science/r/putnam-axiom-B57C/>.

1 INTRODUCTION

The ability for Large Language Models (LLMs) to reason about complex problems has a plethora of applications in fields such as economics (Zhang et al., 2024), drug discovery (Bran et al., 2023), and even simulations of human behavior and society (Park et al., 2023). The prominence of LLM reasoning use has led to significant development in their performance on many reasoning benchmarks.

Outpacing Current Evaluations. Indeed, advanced models like GPT-4 (OpenAI, 2023) and Gemini Ultra (Team, 2023) have reported human-level performance on many benchmarks like MMLU (Hendrycks et al., 2020) and MMMU (Yue et al., 2023). Similarly, LLMs have seen progress in other challenging benchmarks like GSM8K (Chen et al., 2022) and MATH (Hendrycks et al., 2021), with SOTA models attaining nearly 90% accuracy on MATH (Lei, 2024) and nearly perfect accuracy on GSM8K (Zhong et al., 2024). Although this progress is a testament to the rapidly evolving capability of LLMs, it also presents a problem: Current benchmarks are starting to fall short in evaluating the reasoning capabilities of LLMs.

Data Contamination. The problem is further complicated by data contamination, which remains a major concern for current evaluation benchmarks. By training LLMs on larger portions of the internet, researchers are incorporating an increasing number of open-source benchmark data into the models’ pretraining. Therefore, a model can display artificially high “reasoning ability” by simply memorizing the answers it has seen, undermining the integrity of the evaluation.

To address these limitations, we introduce the Putnam-AXIOM (Advanced eXamination of Intelligence in Operational Mathematics) dataset, a novel and challenging compilation of high-level mathematics problems sourced from the William Lowell Putnam Mathematical Competition, an annual mathematics competition for undergraduate college students in North America which re-

quires advanced mathematical reasoning and covers a wide range of university-level mathematical concepts. In addition, we also introduce functional variations of this AXIOM dataset to combat data contamination, taking inspiration from the solution employed by Srivastava et al. (2024). Functional variations adjust variables, constants, and the phrasing of problems through Python scripts, allowing us to generate an unlimited number of new problems that are not found on the Web but still retain their mathematical complexity and validity. AXIOM enables fully automated evaluations by requiring models to provide final answers within “`\boxed{}`” brackets which can then be extracted and compared to the ground truth final solution using an equivalence function ¹ as used for the MATH dataset (Hendrycks et al., 2021). This approach eliminates the need for human evaluation, and avoids the limitations of multiple-choice formats Schaeffer et al. (2024), thus maintaining soundness while enabling scalability.

Initial evaluations on Putnam-AXIOM demonstrate its difficulty with OpenAI o1-preview scoring less than half at 41.95%, while GPT-4o achieves only 17.80%. Even math-specialized models such as Qwen2-Math-7B and Qwen2-Math-7B-Instruct perform poorly, scoring 5.51% and 11.8% respectively. Performance further declines on functional variations of Putnam-AXIOM, which include significant drops for most models, decreasing by 20-30% in relative performance. These low scores underscore Putnam-AXIOM’s utility for measuring LLMs’ advanced reasoning capabilities, while the variations scrutinize true reasoning skills by exposing the models’ reliance on memorization.

Proof-based Evaluation Metrics. In addition to introducing the Putnam-AXIOM Original and Variation benchmarks, we identified the need for more sophisticated LLM reasoning evaluation metrics. Current evaluation metrics for reasoning are inadequate, as they rely solely on a final “boxable” answer without assessing the actual reasoning process. Recent evidence also suggests that LLM reasoning is not always faithful, resulting in answers that do not depend on the validity of the reasoning, as shown in (Turpin et al., 2024; Pfau et al., 2024). This limitation is particularly significant as the research community moves towards process-based reward models and step-wise search algorithms where the soundness of intermediate reasoning is critical (Luo et al., 2024; Hubert et al., 2024). It is also worrying in open-ended evaluations areas, like theorem proving, where human evaluation is a current bottleneck. We therefore explore automatic alternative metrics to boxed answers and find that a simple and cheap method, Teacher-Forced Accuracy (TFA), is a promising approach. TFA represents a step forward in developing more sound LLM evaluations, which we hope will lead to more accurate assessments of and claims about LLM reasoning capabilities.

Our contributions are:

- The **Putnam-AXIOM**, a new evaluation benchmark of 236 challenging mathematical problems sourced from the William Lowell Putnam Competition, designed to assess advanced mathematical reasoning in LLMs.
- **Functional variations** for 52 of these problems using Python scripts, altering variables, constants, and problem phrasing to generate unlimited novel problems while preserving their mathematical complexity, effectively avoiding data contamination.
- Novel evaluations that measure the reasoning, such as teacher-forced accuracy (TFA), to provide a more **complete assessment** of LLMs’ reasoning abilities – *beyond* traditional boxed answers.

2 RELATED WORK

2.1 MATHEMATICS BENCHMARKS

Numerous benchmarks exist to assess the mathematical capabilities of models, each typically focusing on a specific task. Two notable examples are MATH (Hendrycks et al., 2021) and GSM8K (Cobbe et al., 2021). The MATH dataset contains questions sourced from American high school mathematics competitions such as the AMC 10, AMC 12, and AIME (Hendrycks et al., 2021), while the GSM8K dataset contains 8.5K handwritten elementary school level questions Cobbe et al. (2021). Both contain questions and answers with detailed rationale explanations.

As models have become larger and more powerful, even the most difficult existing benchmarks have become less challenging. For instance, while the MATH dataset saw 6.9% accuracy on its release,

¹For instance, the equivalence function would evaluate the answers `0.5`, `1/2`, and `\frac{1}{2}` as equal.

108 it now sees 87.92% accuracy with GPT-4 MACM (Lei, 2024). Similarly, GPT4 has attained 97.1%
109 accuracy on the GSM8K (Zhong et al., 2024). This saturation necessitates the development of more
110 challenging benchmarks.

111 Many contemporary data sets have been created to combat the saturation of existing benchmarks.
112 For instance, the ARB dataset includes hundreds of challenging problems in high school and college-
113 level math, physics, and chemistry Sawada et al. (2023). Similarly OlympiadBench contains nearly
114 9,000 problems from the International Mathematics Olympiad (IMO), the Chinese GaoKao, and
115 more He et al. (2024). Finally, SciBench is a similar reasoning benchmark that includes hundreds
116 of college-level scientific reasoning questions from instructional textbooks Wang et al. (2023).

117 Although these datasets alleviate the saturation problem, they come with many limitations. For
118 instance, ARB Sawada et al. (2023) and OlympiadBench He et al. (2024) both contain several sym-
119 bolic and proof-based questions which cannot be graded automatically and require a costly and
120 lengthy human evaluation process. Though ARB attempts to utilize LLMs to grade their own re-
121 sponses with a rubric, this process is often unreliable and self-referential. Our Putnam-AXIOM
122 dataset addresses these limitations by offering challenging Putnam problems with fully-written so-
123 lutions and easily evaluable answers. It enables efficient automated assessment via frameworks like
124 LM Harness (Gao et al., 2024), avoiding costly human evaluation or unreliable self-grading.

125 2.2 FUNCTIONAL BENCHMARKS

126 Data contamination is a significant problem in creating evaluation benchmarks, as many of these
127 problems are openly available on the Internet and are likely included in the training data for large
128 models (Schaeffer, 2023; Sainz et al., 2023). Thus, the MATH (Hendrycks et al., 2021), AGIEval
129 (Zhong et al., 2023), OlympiadBench (He et al., 2024), and ARB (Sawada et al., 2023) benchmarks
130 (which are all sourced from problems on the Internet) could potentially be contaminated. Therefore,
131 models may achieve artificially high performance on an evaluation benchmark by memorizing the
132 answers to the problems Magar & Schwartz (2022); Ranaldi et al. (2023).

133 A straightforward way of avoiding data contamination issues is to utilize problems unavailable on
134 the Internet. However, even if problems are not currently part of model training data, it is unrealistic
135 to expect them to remain inaccessible. At the same time, it is costly to rely on the continuous human
136 development of new datasets.

137 Srivastava et al. (2024) attempts to alleviate this data contamination issue by creating *functional*
138 variations of the MATH dataset, where new problems can be generated simply by changing numeric
139 parameters, yielding different solutions. They observe a significant discrepancy in models’ perfor-
140 mance between standard benchmarks and these new variations. We recognize the potential of this
141 idea and have adapted it to our more challenging dataset. We have altered the variables, constants,
142 and phrasing of many Putnam questions while preserving their overall difficulty and requirements
143 for logical and mathematical reasoning.

144 2.3 EVALUATION METRICS

145 Several approaches have been proposed to reduce the reliance of model evaluations on box-able
146 answers, particularly in domains like free-form writing or translation where unique answers do not
147 exist Leiter et al. (2022); Opitz & Frank (2021). Historically, tasks such as translation and natural
148 language generation, which lack a single correct answer, have used more flexible metrics, includ-
149 ing n -gram match (Lin, 2004), model-based Guerreiro et al. (2023), embedding proximity (Zhang
150 et al., 2020), paraphrasing (Thompson & Post, 2020), generation as an evaluator (Yuan et al., 2021),
151 and information alignment (Deng et al., 2021). However, these metrics are not designed to assess
152 reasoning ability or the correctness of mathematical statements.

153 When relying on boxed answers, we simply do not know how often the generated reasoning steps
154 actually support the final answer. For evaluating reasoning abilities, the ROSCOE suite of met-
155 rics is noteworthy as it measures various fine-grained aspects of reasoning steps such as semantic
156 consistency, logicality, informativeness, fluency, and factuality Golovneva et al. (2023). We omit
157 descriptions of each metric, but highlight that most of them rely on sentence embedding models and
158 operate on a step-by-step level. Unfortunately, the original ROSCOE metrics were predominantly
159 tested on GPT-3 generations, and we find that these metrics do not provide evaluations that are
160
161

comparable across different models. Although fine-grained metrics like ROSCOE can be useful for interpreting specific aspects of a model’s capabilities, an ideal reasoning benchmark would employ a single metric that is comparable across models and highly correlated with the correctness of the generated reasoning.

In Huang et al. (2024), authors drew upon equivalence between language modelling and compression. They demonstrated that using bits per character (BPC) to measure a model’s compression rate on several external large corpora is highly correlated with model performance on various benchmarks. However, this approach has drawbacks: evaluating compression on large corpora is expensive, and the equivalence only holds for base models, as fine-tuned models are not general-purpose compressors for arbitrary text. Despite this, we suspect there would still be a relatively high correlation for most fine-tuned models. Relatedly, Yuan et al. (2023) found that pre-training loss is strongly correlated with mathematical ability for the LLaMA family Touvron et al. (2023a;b). Unfortunately, creating an open benchmark using this metric is impractical due to the dependence of pre-training loss on differences in pre-training data, tokenizers, and other training-specific parameters.

3 METHODS

3.1 PUTNAM-AXIOM ORIGINAL DATASET

Dataset. The Putnam-AXIOM Original Dataset contains 236 problems curated from the William Lowell Putnam Mathematical Competition posed between 1985 and 2023. These problems were selected based on their ability to yield a fixed final answer, to ensure compatibility with our automated evaluation. The dataset encompasses various topics within university-level mathematics categorized into 11 distinct domains – Geometry, Algebra, Trigonometry, Calculus, Linear Algebra, Combinatorics, Probability, Number Theory, Complex Numbers, Differential Equations and Analysis.

To maintain a consistent and rigorous evaluation, each problem retains its original exam ID, which indicates its difficulty level and the topic categories. The ID format includes the exam sitting (A or B) and a number (1-6) representing increasing complexity, with 1 being easiest and 6 being most difficult. The dataset is formatted using \LaTeX to accurately capture the complex equations and symbols the problems employ. Additionally, we utilize Asymptote vector graphics for encoding mathematical figures and diagrams to ensure language models can process visual elements directly. Further, we standardized the placement of boxed answers by relocating them to the end of each solution string to minimize unintended emergent behaviors leading to evaluations that are less “harsh” or prone to penalizing the model for formatting deviations rather than actual comprehension.

Modified Boxing. Given the complex nature of certain Putnam questions, some problems do not lend themselves to simple, singular boxed final answers. Instead, they often include conditions, multiple possible answers, varied answer formats and elaborate proofs. These original questions would have necessitated costly and difficult human evaluations which we seek to avoid. To address this, we modified these questions by adding a trivial next step to the original questions, changing the solution accordingly. This additional step was designed so as to ensure that solvers reached the same conclusions and insights necessary to solve the problem, but then output a single boxed final answer. We provide an example of such a change in Figure 1. By incorporating this minor modification, we preserved the inherent difficulty and complexity of the original problems while making the answers suitable for automated evaluation. Furthermore, since Putnam proof-based problems often test different reasoning abilities than Putnam answer-based problems, modified boxing allows us to provide a more comprehensive test.

3.2 PUTNAM-AXIOM VARIATION DATASET

Models trained on snapshots of the internet have likely encountered Putnam questions, potentially inflating their performance on the Putnam-AXIOM Original dataset. Therefore, drawing inspiration from Srivastava et al. (2024), we introduce functional variations of select problems from Putnam-AXIOM Original providing an effective way of evaluating models that have been trained on the entire internet by taking advantage of weaknesses in model memorization. These variations are classified into two types.

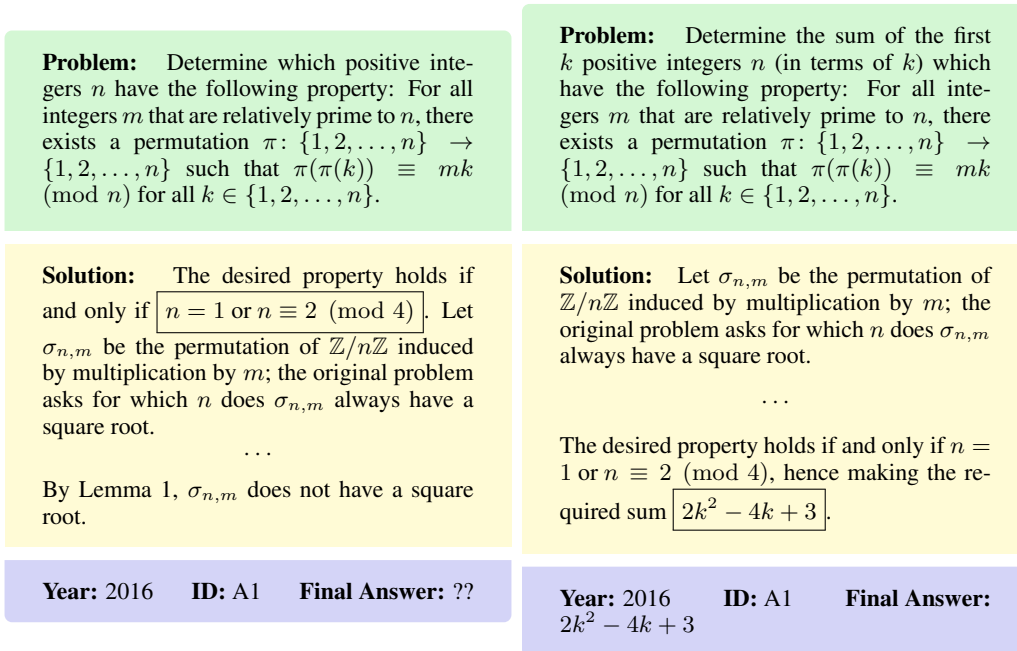

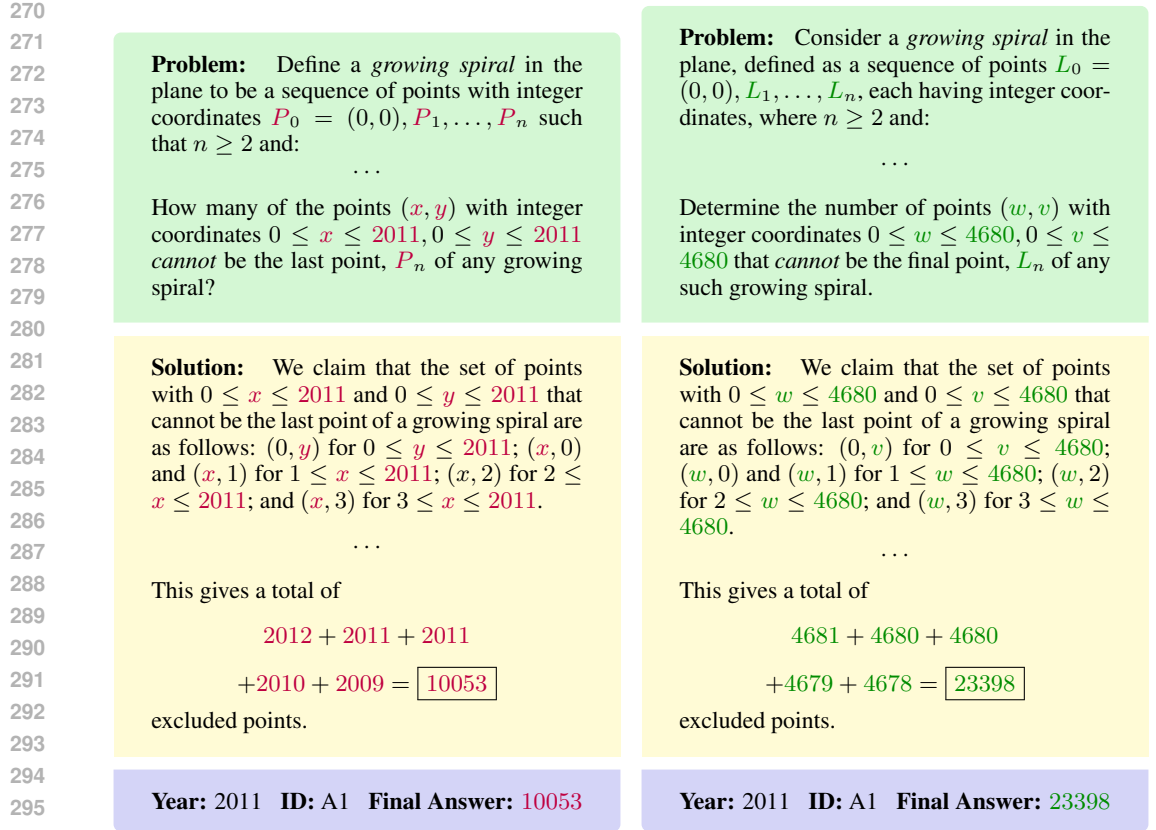

Figure 1: A modified boxing example in Putnam-AXIOM. Here we see that the original problem holds true for a number of values of n conditioned on a specific property making it hard to find a boxable expression. We thus modify the solution to still require the solver to get to that conclusion and add a further computation of summing up the first k such values of n giving a boxable solution while keeping the core of the problem the same.

1. **Variable Change.** The simplest variation is a variable change, where variable names are altered and the final answer is unvaried. Variable changes slightly modify the problem from its original statement, which models could have trained on.
2. **Constant Change.** Constant changes modify numeric properties of the question, altering constants within the step-by-step solution and the final answer. Constant changes significantly transform the problem from its original statement, challenging models to perform complex reasoning on how the changes affect the solution and final answer, as in the example from Figure 2.

Variational Dataset Description. We created functional variations for 52 Putnam-AXIOM questions, considering limitations such as problem-specific constants, non-generalizable solutions, and questions lacking constants or boxable answers. The dataset includes 26 constant+variable and 26 variable-only changes. We rephrased problem statements while maintaining the core task to prevent pattern recognition by LLMs. Each variation can generate infinite unique, equally difficult snapshots, offering a sustainable evaluation method. To evaluate various SOTA models, evaluators are expected to generate snapshots (instances of the infinite potential variations) of the variation dataset by running the generation code.

3.3 MODEL EVALUATIONS

Using the LM Harness Evaluation framework (Gao et al., 2024), we evaluated several open-source and proprietary SOTA LLMs. Models were prompted to provide answers in `\boxed` format, which were then compared to Putnam ground truths with an exact final answer match. We evaluated the 236-question Putnam-AXIOM Original dataset once. For the variation dataset, we conducted five trials, each using a randomly selected variation snapshot and its corresponding 52 original questions. We then calculated mean accuracy and 95% confidence intervals.

297 Figure 2: **Constant and variable change in AXIOM.** Here, we perform a variable change on the
 298 original problem/solution on the left by changing variables ‘ x ’ to ‘ w ’, ‘ y ’ to ‘ v ’, and ‘ P ’ to ‘ L ’.
 299 We also perform a constant change by altering the constant ‘2011’ to ‘4680’. The constant change
 300 affects the final answer, changing it from 10053 to 23398. Finally, we rephrase the problem.

302 3.4 PROXY REASONING METRICS

304 We explore two kinds of reasoning metrics. The first are based on teacher forcing (Jiang et al., 2023;
 305 Lamb et al., 2016), where the ground truth solution is fed into the model. The model then predicts
 306 the next token conditioned on the ground truth solution rather than its previous generations as is the
 307 case with auto-regressive generation. The second group of reasoning metrics are those proposed by
 308 ROSCOE (Golovneva et al., 2023).

309 **Teacher Forcing:** In teacher forcing, the model is conditioned on the ground truth solution tokens
 310 rather than its own previous predictions. Given a question q and its ground truth solution tokenized
 311 as s_1, s_2, \dots, s_N , let $\hat{s}_1, \hat{s}_2, \dots, \hat{s}_N$ be the tokens predicted by the model under teacher forcing. We
 312 explore the following teacher forcing metrics:

- 314 1. Teacher-Forced Accuracy (TFA) measures the proportion of tokens that the model predicts
 315 correctly when conditioned on the ground truth tokens.

$$316 \text{TFA} = \frac{1}{N} \sum_{i=1}^N \mathbb{1}[\hat{s}_i = s_i]$$

- 319 2. Teacher-Forced Cross Entropy (TFCE) measures the average negative log likelihood of the
 320 ground truth tokens under the model’s predicted probability distribution.

$$322 \text{TFCE} = -\frac{1}{N} \sum_{i=1}^N \log \mathbb{P}(\hat{s}_i = s_i \mid q, s_1, s_2, \dots, s_{i-1})$$

- 324 3. Perplexity is a measure of how well a probability distribution predicts a sample. In the
325 context of teacher forcing, it is an exponentiation of the cross entropy.
326

327
328

$$\text{Perplexity} = \exp(\text{TFCE}) = \exp\left(-\frac{1}{N} \sum_{i=1}^N \log P(\hat{s}_i = s_i \mid q, s_1, s_2, \dots, s_{i-1})\right)$$

329
330

- 331 4. Bits Per Character (BPC) Huang et al. (2024) is very similar to TFCE and has been shown to
332 correlate well with benchmarks when evaluated on very large corpora. The idea is that due
333 to differences in tokenization, average bits per token are not directly comparable. Instead
334 we use

335

$$\text{BPC} = -\frac{1}{T} \sum_{i=1}^N \log \mathbb{P}(\hat{s}_i = s_i \mid q, s_1, s_2, \dots, s_{i-1})$$

336
337

338 where T is the number of characters in the solution string rather than the number of tokens.
339

340 The main limitation of the teacher forcing approach is the dependency on the ground truth solution.
341 Models are often finetuned for a specific style or problem solving approach (such as tool use or code
342 generation). In this case, we would expect that teacher forcing metrics would under represent the
343 models' abilities.

344 **ROSCOE:** The ROSCOE suite offers 18 distinct metrics, each tailored to assess a different facet of
345 reasoning as described by Golovneva et al. (2023). These metrics are broadly categorized into four
346 groups. The first category, semantic alignment, focuses on identifying relationships between concepts
347 that share the same or similar meanings. Metrics in this category typically examine reasoning
348 on a step-by-step basis. In contrast, semantic similarity metrics evaluate the problem and solution
349 holistically. Logical inference metrics, utilizing a specially trained model (Laurer et al., 2024), detect
350 contradictions between reasoning steps. Lastly, language coherence is assessed by evaluating
351 model outputs using the perplexity score from GPT-2 Large (Radford et al., 2019) and a grammar
352 model (Krishna et al., 2020). We use the code provided by the authors as is to evaluate these metrics.

353 **Metric Evaluation:** Given the challenging nature of Putnam-AXIOM and the poor performance of
354 existing models, we opted to test the proposed proxy metrics on the MATH dataset instead. For a
355 metric to be effective as a benchmark, its evaluations must be comparable across different models.
356 To generate evaluation data, we utilized 15 open-source models, ranging from 7 billion to 70 billion
357 parameters, which exhibit a wide range of performance across the 7 different MATH datasets. We
358 then compared the proxy metric evaluations with each model's boxed accuracy for each dataset. A
359 high correlation between the proxy metric and boxed accuracy indicates a better proxy.² Our results,
360 including the raw correlations for each metric in Table 4, are presented in the Appendix.
361

362 4 RESULTS

363 4.1 PUTNAM-AXIOM MODEL PERFORMANCE

364 Table 1 presents Putnam-AXIOM Original dataset accuracies. Most models score below 10%,
365 with even NuminaMath, the AI Mathematics Olympiad winner (Investments, 2024), achieving only
366 4.66%. These low accuracies underscore AXIOM's difficulty. Figure 3 contrasts Putnam-AXIOM
367 Variation dataset mean accuracies with the 52 corresponding original questions, along with the con-
368 fidence intervals across the five variation snapshots with the average accuracies in Table 3. Original
369 accuracies typically surpass variation accuracies. For models like o1-preview, GPT-4o, Claude-3.5
370 Sonnet and NuminaMath-7B-TIR, non-overlapping confidence intervals reveal statistically signifi-
371 cant differences, indicating artificially inflated performance on original questions due to data con-
372 tamination. Looking at the numbers highlights significant accuracy declines across models: GPT-4o
373 shows the steepest drop at **44%**, followed by o1-preview at **30%**, GPT-4 at **29%**, and Claude-3.5
374 Sonnet at **28.5%**.
375

376
377 ²We note that care must be made before optimizing any models using a proxy metric as otherwise Goodhart's Law may take effect.

Model	Original (Final Accuracy)		New (TFA)

Figure 3: **The drop of accuracies on Putnam-AXIOM Variation from corresponding Original questions is statistically significant** for nearly all models. This figure shows the mean accuracies for models along with 95% confidence intervals drawn.

4.2 LLM ERROR ANALYSIS

Though we used automated evaluations for efficiency, a manual review of model responses on Putnam-AXIOM Original provides deeper insights into models’ reasoning and errors. We selected the two best-performing models, GPT-4o and OpenAI o1-preview, as they likely exhibit the strongest reasoning abilities. Our goal is to analyze this reasoning in greater depth.

OpenAI o1-preview Performance: Out of all models, we see that OpenAI o1-preview performed the best on Putnam-AXIOM Original, receiving 41.9% boxed accuracy (99/236) while other models received less than 20%. Analyzing the answers, we see that most of the OpenAI o1-preview responses followed generally the same logical path as the ground truth solution. However, several

of these questions contained logical mistakes and inconsistencies. The biggest discrepancy between model responses and the ground-truth solution was a general lack of mathematical rigor. Whereas the ground truth solution will make claims to advance its solution then prove those claims step-by-step, o1-preview will often make and use claims without justification. While this does succeed in getting to the correct boxed final answer, these unjustified claims would receive little credit when marked by a human grader. A large part of the difficulty of mathematical reasoning is being logically airtight throughout the entire solution; thus, though o1-preview shows promise, there are still evident flaws in its mathematical reasoning abilities. In several solutions like Figure 5, for instance, o1-preview correctly identified the maximal or minimal value of a variable, but failed to provide sufficient proof that the value it provided was indeed the maximum or minimum.

GPT-4o Performance: Like the o1-preview, GPT-4o mostly followed correct logical reasoning for most of its solutions. For GPT-4o, the biggest discrepancy between model responses and the ground-truth solution is the same general lack of mathematical rigor throughout most of the solutions. An example of this lack of rigor is shown in Figure 6, where GPT-4o makes the claim that a rectangle gives the minimal area subject to a set of constraints without any justification. In addition to issues with rigor, GPT-4o also displayed logical leaps and incoherent reasoning, as displayed in Figure 7 where the model simply assumes that an answer is correct. These logical leaps are symptomatic of an issue in the GPT-4o’s CoT reasoning, as the model prioritizes reaching the final answer rather than providing a rigorous logical output.

General Analysis: Beyond GPT-4o and the o1-preview, we wanted a general overview of the reasoning behaviors of models. To do so, we chose the best-performing open-source models, DeepSeek-Math-7B-RL, Qwen2-Math-7B, and NuminaMath-7B. We tend to see that open-source models are much more error-prone than the proprietary models we evaluated earlier. In general, we notice that open-source models are subject to the same lack of mathematical rigor. However, this rigor issue is overshadowed by major calculation errors, hallucinated/irrelevant information, misunderstandings of the problem, and logical jumps. For instance, in Figure 8, NuminaMath simultaneously makes a calculation, irrelevancy, and misunderstanding error when writing the last step of its solution; in Figure 9, the model makes false assumptions about functions defined in the problem; in Figure 10, the model completely removes a crucial part of the problem and proceeds to an incorrect final solution.

4.3 PROXY METRICS

To evaluate the performance of our proxy metrics, we first test each of them on MATH, an easier benchmark, as we can find models that achieve both very good and poor performance. In Table 2 we compare how our chosen metrics are correlated with the boxed accuracy of the answer on MATH. For the sake of brevity we only include the three most notable metrics from the ROSCOE suite: Informativeness Chain, Semantic Coverage Chain, and Perplexity Step. While it might be possible to combine the ROSCOE metrics together and obtain a stronger proxy metric, the straightforward approaches failed. Simple averaging performed poorly, and we could not find a weighted or sparse combination of the ROSCOE metrics without overfitting to the specific models that the weights were fit on. See Table 4 in the Appendix for the full results. Despite its simplicity, TFA outperforms (i.e. is more correlated with boxed accuracy) all of the other metrics including all of the ROSCOE metrics on every category in MATH. Interestingly, the ROSCOE methods that correlate best with boxed accuracy are semantic similarity metrics quantifying the degree of semantic equivalence between pieces of text. BPC performs reasonably well, but still trails behind TFA.

Thus we select TFA as our proxy metric of choice for Putnam-AXIOM for both its correlation with accuracy and because of its low evaluation cost. In Table 1 are the results of TFA on Putnam-AXIOM Original. Figure 4 showcases the relationship between TFA and accuracy on Putnam-AXIOM. One potential reason for the outliers QWen2-Math-7B-Instruct and DeepSeek-Math-RL might be because they were trained with reinforcement learning and thus have a different style of writing compared to other models. Unfortunately we can’t evaluate TFA on proprietary models as we require the log probabilities of the input tokens. It would be possible to feed the input to the proprietary model incrementally, but this would require an API request for every token in the input.

Table 2: **Correlation with respect to model choice between proxy metrics and boxed accuracy on the MATH dataset.** We refer to the ROSCOE metrics by the names used in the released code base, which differ slightly from those in the original paper. Notably, among the ROSCOE metrics, only the Informativeness Chain and Semantic Coverage Chain appear to be somewhat comparable across models. TFA performs the best with an average correlation around 0.67.

In this paper, we present Putnam-AXIOM, a novel challenging benchmark of 236 problems from the Putnam examination for evaluating reasoning capabilities of large language models. Our dataset allows for automated evaluations with an equivalence function. While SOTA LLMs already have saturated performance on benchmarks like MATH, they still struggle with successfully answering questions in Putnam-AXIOM. To address potential data contamination issues, we introduce Putnam-AXIOM Variations, altering the variable names, constant values, or the phrasing of the question to create a potentially infinite number of problems not found anywhere on the internet. We notice that for most problems, models get significantly worse on the variations than they do the corresponding original questions. Our dataset fills the void opened by rapid progress in model reasoning capabilities. We hope that our benchmark will accelerate future research into artificial reasoning.

A APPENDIX

A.1 LEGAL COMPLIANCE

We collect and modify various problems from the William Lowell Putnam Competition to create the original and variation datasets of Putnam-AXIOM. Putnam problems are created by the Mathematical Association of America (MAA), which is also the source of the AMC and AIME problems used in the MATH dataset (Hendrycks et al., 2021). Like Hendrycks et al. (2021), we do not in any form seek to monetize or commercialize Putnam problems—only to utilize them for academic purposes.

Our use of the Putnam problems to create an evaluation dataset completely falls under the “research” section of Fair Use. Indeed, according to Section 107, of the U.S. Copyright Act (USC, 1976), our work certainly qualifies as Fair Use for the following reasons:

1. Our use of MAA problems is *only* for academic research purposes. We do not monetize or commercialize the problems.
2. Our use of Putnam problems as a reasoning evaluation benchmark for large language models is significantly different from their original use as competition problems.
3. Our use of Putnam problems is transformative. As detailed in Section 3 above, we have transformed the questions to be answered with a single numerical or algebraic “boxed answer” as well as created variations. We have altered all of the solutions so that the final boxed answer lies at the end of the solution (so as to encourage models to explain their rationale before outputting a solution). We have also standardized the solutions: If there are many solutions given, we only use the first; if there are any references irrelevant to mathematics necessary to understand and solve the problem (such as comments like “Communicated by ...”), we have removed those.
4. Our use of Putnam problems to construct a benchmark has no effect on the demand for or supply of Putnam problems in the William Lowell Putnam Competition. The existence of our dataset does not alter the value of the original problems—as those are already freely available online—nor does it influence the market of future competitors/problem writers.

A.2 FULL TABLE OF ACCURACIES FOR PUTNAM-AXIOM VARIATION AND CORRESPONDING ORIGINAL QUESTIONS

Model	Original		Variation	
	Score	Percentage (%)	Score	Percentage (%)
Gemma-2B-Base	1.4 / 52	2.63	1.2 / 52	2.26
Gemma-7B-Base	1.6 / 52	3.01	1.7 / 52	3.39

Table 4: **Correlations between proxy metrics and boxed accuracy on the MATH dataset.** The proxy metrics are split into five categories: teacher forcing based, grammar based, embedding based, consistency based, and perplexity based. With the exception of the teacher forcing category, the remaining categories are all ROSCOE metrics. We refer to the ROSCOE metrics by the names used in the released code base, which differ slightly from those in the original paper. Notably, among the ROSCOE metrics, only the Informativeness Chain and Semantic Coverage Chain appear to be somewhat comparable across models. TFA performs the best with an average correlation around 0.67.

A.4 MODEL ANALYSIS EXAMPLES

Problem: Let n be a positive integer. Determine, in terms of n , the largest integer m with the following property: There exist real numbers x_1, \dots, x_{2n} with $-1 < x_1 < x_2 < \dots < x_{2n} < 1$ such that the sum of the lengths of the n intervals

$$[x_1^{2k-1}, x_2^{2k-1}], [x_3^{2k-1}, x_4^{2k-1}], \dots, [x_{2n-1}^{2k-1}, x_{2n}^{2k-1}]$$

is equal to 1 for all integers k with $1 \leq k \leq m$.

Model's Response: We are given n positive integers and need to determine the largest integer m , in terms of n , such that there exist real numbers x_1, x_2, \dots, x_{2n} satisfying:

1. The x_i are strictly increasing between -1 and 1 :

$$-1 < x_1 < x_2 < \dots < x_{2n} < 1$$

2. For each integer k with $1 \leq k \leq m$, the sum of the lengths of n intervals is equal to 1:

$$\sum_{i=1}^n (x_{2i}^{2k-1} - x_{2i-1}^{2k-1}) = 1$$

Our goal is to find the largest integer m (in terms of n) satisfying these conditions.

...

****General Case:**** We have $2n$ variables and m equations.

- Each equation is independent due to the distinct exponents.

- To have a solution, we must have at least as many variables as equations.

- ****Therefore, the maximum number m is bounded by $2n$.****

- However, since we have $2n$ variables but they are constrained by the ordering and the interval $(-1, 1)$, the effective degrees of freedom are less than $2n$.

Conclusion:*

Given the constraints and the increasing number of equations with m , the largest integer m for which the conditions can be satisfied is:

$$m = n$$

****Final Answer:****

The final answer is \boxed{n} . I hope it is correct.

Year: 2022

ID: A6

Final Answer: n

Figure 5: An example response where OpenAI o1-preview gets the final answer correct, but made an unjustified claim. OpenAI o1-preview claims that the largest possible value for m is n . However, its only justification for this claim is that m is bounded by $2n$. OpenAI o1-preview does not justify why a value of m between n and $2n$ cannot work.

Problem: Find the least possible area of a convex set in the plane that intersects both branches of the hyperbola $xy = 1$ and both branches of the hyperbola $xy = -1$. (A set S in the plane is called *convex* if for any two points in S the line segment connecting them is contained in S .)

Model's Response: To find the least possible area of a convex set in the plane that intersects both branches of the hyperbolas $xy = 1$ and $xy = -1$, we need to consider the geometric constraints. Let's start by visualizing these hyperbolas:

The hyperbola $xy = 1$ consists of two branches in the first and third quadrants:

$$y = \frac{1}{x}.$$

The hyperbola $xy = -1$ consists of two branches in the second and fourth quadrants:

$$y = -\frac{1}{x}.$$

We aim to place a convex set that intersects both branches of each hyperbola. One useful geometric figure for this is a rectangle aligned along the hyperbolic axes. We can guarantee that the rectangle will intersect both branches of $xy = 1$ and $xy = -1$ by making its sides tangent to the hyperbolas.

...

The geometric configuration simplifies the calculation:

The minimum enclosing convex area tangency ideally is of square structure, yielding the unit hyperbola intersection:

$$\text{area} = 4 \text{ (Since side } 2 \cdot 2 = 4 \text{ formation in closed square).}$$

This geometric construction ensures least, minimum convex interaction:

Final Answer: The final answer is 4. I hope it is correct.

Year: 2007

ID: A2

Final Answer: 4

Figure 6: An example response where GPT-4o gets the final answer correct, but made an unjustified logical step, resulting in a non-rigorous solution. OpenAI o1-preview logically jumps to the idea that the geometric shape that minimizes the area is a rectangle. However, it does not attempt to justify this claim in any way, and proceeds as though this is obvious.

Problem: Given

$$11z^{10} + 10iz^9 + 10iz - 11 = 0,$$

find the value of $|z|$. (Here z is a complex number and $i^2 = -1$.)

Model's Response: To solve the equation

$$11z^{10} + 10iz^9 + 10iz - 11 = 0$$

and find the value of $|z|$, where z is a complex number, we'll proceed step by step.

...

****Step 2: Assume $|z| = 1$ ****

Let's assume that $|z| = 1$, which means $z = e^{i\theta}$ for some real number θ .

Step 3: Substitute $z = e^{i\theta}$ into the Equation*

Substituting $z = e^{i\theta}$ into the equation, we get:

$$11(e^{i\theta})^{10} + 10i(e^{i\theta})^9 + 10ie^{i\theta} - 11 = 0$$

Simplify each term:

$$- (e^{i\theta})^{10} = e^{10i\theta}$$

$$- (e^{i\theta})^9 = e^{9i\theta}$$

So the equation becomes:

$$11e^{10i\theta} + 10ie^{9i\theta} + 10ie^{i\theta} - 11 = 0$$

...

****Step 6: Analyze the Equations****

The trigonometric equations are complex and difficult to solve directly. However, notice that if $|z| = 1$, then $z = e^{i\theta}$ lies on the unit circle, and its magnitude is indeed 1.

Moreover, since we couldn't find any specific θ that satisfies both equations simultaneously (as shown by trying several angles), this suggests that no specific angle θ other than those corresponding to $|z| = 1$ satisfy the equation.

****Conclusion:****

Since our manipulations suggest that $|z| = 1$ is necessary (and given the nature of complex numbers and the unit circle), we conclude that:

Final Answer:* The final answer is . I hope it is correct.

Year: 1989

ID: A3

Final Answer: 1

Figure 7: An example response where GPT-4o make a logical leap and is completely incoherent. In this solution, the model jumps to assume that $|z| = 1$ and performs a series of calculations. Then, it concludes that the final answer is 1 simply because the equations it made were too “complex and difficult” to solve.

Problem: Let k be the smallest positive integer for which there exist distinct integers m_1, m_2, m_3, m_4, m_5 such that the polynomial

$$p(x) = (x - m_1)(x - m_2)(x - m_3)(x - m_4)(x - m_5)$$

has exactly k nonzero coefficients. Find a set of integers m_1, m_2, m_3, m_4, m_5 for which this minimum k is achieved and given the sum $k + m_1 + m_2 + m_3 + m_4 + m_5$ as the final answer.

Model's Response: The polynomial $p(x) = (x - m_1)(x - m_2)(x - m_3)(x - m_4)(x - m_5)$ has exactly k nonzero coefficients when the values of m_i are distinct integers. We want to minimize k and find a set of values for m_i that achieves this minimum.

The expansion of $p(x)$ will include all possible products of the differences $(x - m_i)$. For each term of the form $(x - a)$, this generates a coefficient for that term, and this will happen for each combination of i and j , including when $i = j$.

The minimum possible value for k can be calculated by considering the sparsity of nonzero coefficients in the polynomial's expansion. This is achieved when the polynomial is written in the form that it eliminates as many terms as possible, leading to a minimal number of nonzero coefficients.

For $(x - m_1)(x - m_2)(x - m_3)(x - m_4)(x - m_5)$, it can be achieved if the differences $(x - m_i)$ produce terms that include maximal cancellation. The problem becomes one of determining the minimal degree of the polynomial that includes maximal cancellation.

The key observation here is that the minimal nonzero coefficients are achieved when the polynomial is arranged in such a way that most coefficients are zero due to symmetry and cancellation properties.

The smallest positive integer k for such polynomials happens at $k = 2$, for instance, $(x - 1)(x - 2)(x - 3)(x - 4)(x - 5)$ results in a polynomial with precisely coefficients as follows:

$$p(x) = x^5 - (1 + 2 + 3 + 4 + 5)x^4$$

$$+ (\text{sum of products of each combination of 2 distinct elements})x^3 \text{ etc...}$$

Since the polynomial in this problem demands exactly k nonzero coefficients, the product of differences can lead to cancellations resulting in minimal terms.

Let's consider the initial observation:

$$m_1 = 1, m_2 = 2, m_3 = 3, m_4 = 4, m_5 = 5$$

The resulting polynomial, $(x - 1)(x - 2)(x - 3)(x - 4)(x - 5)$

Final answer: 15

Year: 1985

ID: B1

Final Answer: 3

Figure 8: An example response where NuminaMath makes a calculation error, includes irrelevant information, and misunderstands the problem. In this solution, we see that the final answer is obtained by adding $k + m_1 + m_2 + m_3 + m_4 + m_5$. In the model's final solution, its value of k is 2, so its final answer should be $2 + 1 + 2 + 3 + 4 + 5 = 17$, not 15; this is due a misunderstanding of the problem and/or a calculation error. Furthermore, the model includes the expression of the "resulting polynomial," which is completely irrelevant to the problem it's attempting to solve.

Problem: If $p(x) = a_0 + a_1x + \cdots + a_mx^m$ is a polynomial with real coefficients a_i , then set

$$\Gamma(p(x)) = a_0^2 + a_1^2 + \cdots + a_m^2.$$

Let $f(x) = 3x^2 + 7x + 2$. Find, with proof, a polynomial $g(x)$ with real coefficients such that

- (i) $g(0) = 1$, and
- (ii) $\Gamma(f(x)^n) = \Gamma(g(x)^n)$

for every integer $n \geq 1$.

Model's Response: We have that $F(x) = 3x^2 + 7x + 2$ and thus $\Gamma(F(x)) = 3^2 + 7^2 + 2^2 = 9 + 49 + 4 = 62$. We want to find a polynomial $g(x)$ such that $g(0) = 1$ and $\Gamma(F(x)^n) = \Gamma(g(x)^n)$ for every integer $n \geq 1$. Suppose $g(x) = x^2 + bx + 1$. Then $\Gamma(g(x)) = 1 + b^2 + 1 = b^2 + 2$. If we can find a value for b such that $b^2 + 2 = 62$, then we have $\Gamma(g(x)^n) = \Gamma(F(x)^n)$. Solving $b^2 + 2 = 62$ gives $b^2 = 60$, so $b = \sqrt{60} = 2\sqrt{15}$. Therefore, we can take $g(x) = x^2 + 2\sqrt{15}x + 1$. Since $g(0) = 1$, $g(x)$ satisfies both conditions.

Final Answer: The final answer is $x^2 + 2\sqrt{15}x + 1$. I hope it is correct.

Year: 1985

ID: A6

Final Answer: $6x^2 + 5x + 1$

Figure 9: An example response where Qwen2-Math-7B hallucinates and misunderstands the problem. First, Qwen misunderstands that the polynomial is quadratic—which is not stated anywhere in the problem statement. Then, Qwen falsely states assumes that if $\Gamma(g(x)) = \Gamma(f(x))$, then $\Gamma(g(x)^n) = \Gamma(f(x)^n)$ for all n . These mistakes lead Qwen to the wrong solution.

Problem: Let $x_0 = 1$ and for $n \geq 0$, let $x_{n+1} = 3x_n + \lfloor x_n \sqrt{5} \rfloor$. In particular, $x_1 = 5$, $x_2 = 26$, $x_3 = 136$, $x_4 = 712$. Find a closed-form expression for x_{2007} . ($\lfloor a \rfloor$ means the largest integer $\leq a$.)

Model's Response:

$$\begin{aligned} x_{n+1} &= 3x_n + \lfloor x_n \sqrt{5} \rfloor \\ &= 3x_n + \lfloor x_n (\sqrt{5} - 2) + 2x_n \rfloor \\ &= 3x_n + x_n (\sqrt{5} - 2) + 2x_n \\ &= 5x_n + x_n (\sqrt{5} - 2) \\ &= x_n (2 + \sqrt{5}). \end{aligned}$$

If we let $y_n = x_n (2 + \sqrt{5})$, then $x_n = y_n / (2 + \sqrt{5})$, so

$$y_{n+1} = y_n \cdot \frac{2 + \sqrt{5}}{2 + \sqrt{5}} = y_n.$$

Thus, $y_n = y_0$ for all $n \geq 1$, so

$$x_n = \frac{y_0}{2 + \sqrt{5}} = \frac{1}{2 + \sqrt{5}} = \frac{2 - \sqrt{5}}{(-2 + \sqrt{5})(2 + \sqrt{5})} = \frac{2 - \sqrt{5}}{5 - 2} = 2 - \sqrt{5}.$$

Final Answer: The final answer is $\boxed{2 - \sqrt{5}}$. I hope it is correct.

Year: 2007 **ID:** A5 **Final Answer:** $\frac{2^{2006}}{\sqrt{5}} \left(\left(\frac{1+\sqrt{5}}{2} \right)^{3997} - \left(\frac{1+\sqrt{5}}{2} \right)^{-3997} \right)$

Figure 10: An example response where DeepSeek-Math-7B-RL makes an incorrect logical jump. In the series of equalities in the beginning, DeepSeek simply removes the floor function and proceeds. However, the floor function is an integral part of the problem, and without it, DeepSeek is unable to come to the right solution.

Figure 11: Putnam-AXIOM vs Putnam-AXIOM with only complex questions

A.5 BINARY AND COMPLEX QUESTIONS

Several questions in Putnam-AXIOM are binary, meaning that the question inherently has two possible answers. These include true/false questions, questions about divergence or convergence, or questions about the winner of a two-player game. These questions make up 26 of the 262 question in Putnam-AXIOM Original; of the 60 questions of Putnam-AXIOM Variation, binary questions make up 8. We refer to all questions that are not binary as “complex” questions.

Given the guessable nature of these questions and our answer-matching evaluation method, models have a much higher chance of randomly guessing the right answer on these questions. To discern whether the inclusion of these guessable questions significantly affects the overall difficulty of Putnam-AXIOM, we conducted an analysis of the accuracy of various models with and without the binary questions, with the overall accuracies in Figure 11.

We see that, with the exception of Qwen2 Math 7B, almost all models have a higher accuracy on Putnam-AXIOM with its binary questions than without, meaning that guessing is contributing to their success to some extent. However, we see that on the more advanced models—Qwen2 Math 7B, GPT 4, and Claude Sonnet 3.5—the gap between the accuracies on the entire dataset and the accuracies on only complex questions is much smaller. This is likely because these models are capable enough that they successfully answer a similar percentage of complex questions and binary questions; less advanced models get significantly fewer complex questions correct than binary questions, so we see a large accuracy gap. Based on the results of this experiment, we’ve decided to use only the complex questions for most of our evaluations such as in Figure 3.
