Query-based Cross-Modal Projector Bolstering Mamba Multimodal LLM

Anonymous ACL submission

⁰⁰¹ Abstract

 The Transformer's quadratic complexity with input length imposes an unsustainable compu- tational load on large language models (LLMs). In contrast, the Selective Scan Structured State- Space Model, or Mamba, addresses this com- putational challenge effectively. This paper ex- plores a query-based cross-modal projector de- signed to bolster Mamba's efficiency for vision- language modeling by compressing visual to- kens based on input through the cross-attention mechanism. This innovative projector also re- moves the need for manually designing the 2D scan order of original image features when converting them into an input sequence for Mamba LLM. Experimental results across vari- ous vision-language understanding benchmarks show that the proposed cross-modal projec- tor enhances Mamba-based multimodal LLMs, boosting both performance and throughput.

⁰²¹ 1 Introduction

 Multimodal Large Language Models (MLLMs) aim to extend the capabilities of Large Language Models (LLMs) to various modalities, including text and images. By fusing visual information **into the textual domain, MLLMs effectively lever-** age the powerful language generation and logical reasoning abilities of text-only pre-trained LLMs. This integration has demonstrated significant poten- tial in solving real-world vision-language problems, with diverse applications such as visual question an- swering (VQA) and multimodal dialogue response generation.

 The core element behind this advancement lies in the Transformer [\(Vaswani et al.,](#page-9-0) [2017\)](#page-9-0), an archi- tecture defined by stacked layers of attention mech- anisms capable of scaling up to over 100 billion parameters. Due to its capability and flexibility to capture long-term dependencies, the Transformer can better represent different modalities, serving as a foundational model for MLLMs. Unfortunately, the Transformer also inherits intrinsic bot- **042** tlenecks due to its defining attention mechanism. **043** The computational and memory complexities of **044** self-attention increase quadratically with sequence **045** length, imposing a limit on the input sequence **046** length. Recent efforts have focused on extending **047** the Transformer's context window to overcome this **048** limitation, but the challenge of computational bur- **049** den remains. **050**

To address this issue, the state-space model **051** (SSM) [\(Gu et al.,](#page-8-0) [2021,](#page-8-0) [2022a,](#page-7-0)[b;](#page-8-1) [Fu et al.,](#page-7-1) [2023\)](#page-7-1) **052** has been studied as an alternative architecture for **053** efficiently capturing long-range dependencies. The **054** SSM can be viewed as combining Convolutional **055** Neural Networks (CNNs) and Recurrent Neural **056** Networks (RNNs), enabling parallelizable training **057** and fast inference. The latest advancement in SSMs **058** is Mamba [\(Gu and Dao,](#page-7-2) [2023\)](#page-7-2), which incorporates **059** an input-dependent gating mechanism that enables **060** selective scanning, along with a hardware-aware al- **061** gorithm for efficient computation. Mamba matches **062** or even surpasses the performance of advanced **063** Transformers while achieving faster training and **064** inference speeds, leading to applications in vari- **065** ous domains, including image [\(Zhu et al.,](#page-9-1) [2024;](#page-9-1) **066** [Liu et al.,](#page-8-2) [2024b\)](#page-8-2), speech [\(Jiang et al.,](#page-8-3) [2024;](#page-8-3) [Li](#page-8-4) **067** [and Guo,](#page-8-4) [2024\)](#page-8-4), and video processing [\(Li et al.,](#page-8-5) **068** [2024\)](#page-8-5). The utilization of Mamba architecture for **069** MLLM foundation models has been considered **070** [\(Qiao et al.,](#page-9-2) [2024;](#page-9-2) [Zhao et al.,](#page-9-3) [2024\)](#page-9-3) but not exten- **071** sively explored. Moreover, there remains a limited 072 understanding of the most effective methods for **073** aligning visual information within the textual do- **074** main using Mamba. **075**

Building upon the previous architecture, we in- **076** troduce a non-trivial Mamba-based architecture for **077** cross-modal projection to connect the pre-trained **078** vision encoder and Mamba-based LLM. Inspired **079** by Querying Transformer (Q-Former) [\(Li et al.,](#page-8-6) **080** [2023a\)](#page-8-6), we utilize learnable queries to project **081** vision information from image features into 1D **082**

Figure 1: Model comparison between (a) LLaVA [\(Liu et al.,](#page-8-7) [2023\)](#page-8-7), (b) BLIP-2 [\(Li et al.,](#page-8-6) [2023a\)](#page-8-6), (c) Cobra [\(Zhao](#page-9-3) [et al.,](#page-9-3) [2024\)](#page-9-3), (d) VL-Mamba [\(Qiao et al.,](#page-9-2) [2024\)](#page-9-2), and (e) ours. The key differences stem from the choice of LLM backbone architecture, the design of the projector architecture, and the incorporation of learnable queries for flexibility.

 causal tokens by interleaving the Mamba sequence modeling layer and cross-modal attention. Our architectural design is motivated by three key ob- jectives: (1) eliminating the heuristic choice of 2D visual scan order, (2) effectively and dynami- cally downsampling the projected visual feature se- quence length, and (3) enhancing text-image align- ment by adopting a structure tailored for Mamba- based multimodal modeling. We further propose MLLM with a pre-trained Mamba LLM backbone connected to the vision encoder using the proposed projector. The overall comparison between the pre-vious models and ours is depicted in Figure [1.](#page-1-0)

096 Our contributions can be summarized as follows:

- **097** We propose Querying Mamba, the multimodal **098** connector based on the Mamba module, and **099** the cross-modal attention for adaptive flexibil-**100** ity in downsampling the visual token lengths.
- **101** We propose MLLM based on Querying **102** Mamba and pre-trained Mamba LLM. We **103** meticulously explore a range of choices re-**104** garding the components that integrate these **105** models to boost Mamba's effectiveness in mul-**106** timodal modeling.
- **107** We carry out comprehensive experimental **108** evaluations using multimodal comprehension **109** benchmarks to assess the performance and **110** robustness of our proposed models.

112 2.1 State-Space Models (SSMs) and Mamba

113 Current state-space models are inspired by classi-**114** cal state-space models, which represent continuous

systems that map a 1-dimensional function or se- **115** quence through an implicit latent state. The Linear **116** State Space Layer (LSSL) [\(Gu et al.,](#page-8-0) [2021\)](#page-8-0) was one **117** of the earliest attempts at deep SSMs, aiming to **118** enhance sequence modeling performance by stack- **119** ing multiple SSM layers. Although LSSL demon- **120** strated the potential of deep SSMs for addressing **121** long-range dependencies, its high computational **122** and memory costs rendered it impractical. **123**

The Structured State-Space Model (S4) [\(Gu](#page-7-0) **124** [et al.,](#page-7-0) [2022a\)](#page-7-0) tackled this bottleneck by re- **125** parameterizing the latent matrix through decom- **126** position into low-rank and normal terms. This in- **127** novation led to several variant architectures, such as **128** the Diagonalized State-Space (DSS) [\(Gupta et al.,](#page-8-8) **129** [2022\)](#page-8-8) and S4D [\(Gu et al.,](#page-8-1) [2022b\)](#page-8-1), which enabled **130** more efficient and simplified computation via diag- **131** onalization. However, S4 and its variants can not **132** remember specific past tokens or compare tokens **133** across the sequence—capabilities crucial for lan- **134** [g](#page-7-1)uage modeling. Hungry Hungry Hippos (H3) [\(Fu](#page-7-1) **135** [et al.,](#page-7-1) [2023\)](#page-7-1) aimed to overcome these shortcomings **136** of S4 by incorporating 1-dimensional convolution **137** along the sequence, allowing SSMs to compare **138** and remember past tokens by shifting the input **139** sequence. **140**

The latest work, Mamba [\(Gu and Dao,](#page-7-2) [2023\)](#page-7-2), **141** further refines S4 by introducing a selective mech- **142** anism that utilizes input-dependent latent state pa- **143** rameters, making the model content-aware and **144** enabling it to selectively focus on relevant infor- **145** mation. Mamba also incorporates 1-dimensional **146** convolution shifting from H3 and a gating mecha- **147** nism similar to Long Short-Term Memory (LSTM) **148** [\(Hochreiter and Schmidhuber,](#page-8-9) [1997\)](#page-8-9), which en- **149** hances its ability to handle long sequences with **150**

 increased robustness and flexibility. With parallel associative scanning and a hardware-aware imple- mentation, Mamba achieves efficient training and inference, matching or surpassing the capabilities of advanced Transformers.

 The success of Mamba has led to various adap- tations across different domains. For instance, sev- eral attempts have been made to apply Mamba [i](#page-8-3)n speech separation [\(Li and Guo,](#page-8-4) [2024;](#page-8-4) [Jiang](#page-8-3) [et al.,](#page-8-3) [2024\)](#page-8-3). In computer vision, Vision Mamba (Vim) [\(Zhu et al.,](#page-9-1) [2024\)](#page-9-1) and V-Mamba [\(Liu et al.,](#page-8-2) [2024b\)](#page-8-2) employ bidirectional SSMs to process two- dimensional image data with one-dimensional se- [q](#page-8-10)uence modeling in Mamba. SiMBA [\(Patro and](#page-8-10) [Agneeswaran,](#page-8-10) [2024\)](#page-8-10) further enhances this by incor- porating a channel-mixing layer into the Mamba block, analogous to the role of the feedforward network in the Transformer block.

169 2.2 Multimodal Large Language Models

 With the introduction of ChatGPT [\(Ouyang et al.,](#page-8-11) [2022\)](#page-8-11), also referred to as InstructGPT, Large Lan- guage Models (LLMs) have emerged as a domi- nant approach for real-world natural language pro- cessing tasks. These models, typically featuring billions of parameters and trained on extensive cor- pora, are not only proficient in generating language responses but also in tasks requiring logical com- prehension and reasoning. Although InstructGPT has not been publicly released, the research com- munity has been actively developing open-source LLMs [\(Touvron et al.,](#page-9-4) [2023;](#page-9-4) [Gunasekar et al.,](#page-8-12) [2024;](#page-8-12) [Li et al.,](#page-8-13) [2023c;](#page-8-13) [Zhang et al.,](#page-9-5) [2022\)](#page-9-5), which have shown performance on par with InstructGPT. This progress has led to various adaptations and modi- fications of pre-trained LLMs for diverse applica-**186** tions.

 A notable advancement is the development of Multimodal Large Language Models (MLLMs), which leverage pre-trained LLMs to process multi- modal data. This extends beyond the original text- only domain, integrating capabilities to understand both textual and visual inputs. Models like LLaVA [\(Liu et al.,](#page-8-7) [2023\)](#page-8-7), BLIP[\(Li et al.,](#page-8-14) [2022,](#page-8-14) [2023a\)](#page-8-6), and GPT-4[\(OpenAI,](#page-8-15) [2024\)](#page-8-15) have shown robust perfor- mance in tasks requiring nuanced vision-language integration. These models utilize transformer- based frameworks known for handling long-range dependencies effectively. However, the innate char- acteristic of high computational demands and slow inference rates of these transformer-based frame-works have started to become a target for recent research, leading to the adoption of the more efficient **202** Mamba architecture in MLLMs. This initiative has **203** given rise to models like Cobra[\(Zhao et al.,](#page-9-3) [2024\)](#page-9-3) **204** and VL-Mamba[\(Qiao et al.,](#page-9-2) [2024\)](#page-9-2), which demon- **205** strate promising pathways for enhanced efficiency **206** in MLLM deployment. **207**

Cobra [\(Zhao et al.,](#page-9-3) [2024\)](#page-9-3) employs a state-space **208** model for multimodal tasks, leveraging the linear **209** scalability of the Mamba architecture. It introduces **210** an innovative approach to vision encoding by merg- **211** ing outputs from DINOv2 [\(Oquab et al.,](#page-8-16) [2024\)](#page-8-16) and **212** SigLIP [\(Zhai et al.,](#page-9-6) [2023\)](#page-9-6), thereby generating vi- **213** sual representations that capture both spatial and **214** semantic properties effectively. These outputs are **215** then processed through a learnable projector mod- **216** ule, which aligns the visual and textual features **217** by adjusting the dimensions of the visual represen- **218** tations to match those of the Mamba LLM via a **219** multi-layer perceptron. This approach enables Co- **220** bra to deliver the same volume of output tokens **221** in just 30% of the time required by comparable **222** 3B transformer-based LLMs, such as TinyLLaVA **223** [\(Zhou et al.,](#page-9-7) [2024\)](#page-9-7) or MobileVLM v2 [\(Chu et al.,](#page-7-3) **224** [2024\)](#page-7-3). **225**

Similarly, VL-Mamba [\(Qiao et al.,](#page-9-2) [2024\)](#page-9-2) builds **226** upon a pretrained Mamba framework and intro- **227** duces a novel MultiModal Connector (MMC) ar- **228** chitecture. This connector features a Vision Se- **229** lective Scan (VSS) module and two linear layers, **230** which enhance the causal relationships among image blocks from the vision encoder. Furthermore, **232** this paper assesses the performance difference be- **233** tween the Bidirectional-Scan Mechanism (BSM), **234** which scans the image blocks in both forward and 235 backward directions, and the Cross-Scan Mecha- **236** nism (CSM), which scans both from forward to **237** backward and top to bottom. This paper suggests a **238** preference for the simple BSM, as the two scanning **239** methods show comparable efficacy. **240**

However, the previous projector modules used **241** in Cobra and VL-Mamba have limitations in that **242** these connectors have no flexibility in vision token **243** number, causing longer vision token input, and require manual scan mechanisms that grant causality **245** between image blocks. **246**

3 Method **²⁴⁷**

In this section, we first review the preliminary con- **248** cepts of structured state-space models and Mamba **249** (Sec. [3.1\)](#page-3-0). Then, we describe the details of **250** the Cross-modal Mamba projector, which extracts **251**

Figure 2: Overall architecture of Querying Mamba (left) and the Multimodal Mamba LLM (right) based on the proposed design. Querying Mamba projects the visual information, which is encoded by a pre-trained vision encoder with an additional bidirectional Mamba layer, into the learnable queries with causal Mamba prior via cross attention. The projected vision features work as vision token inputs for pre-trained Mamba LLM.

 the 2-dimensional vision information into a 1- dimensional causal token sequence (Sec. [3.2\)](#page-3-1). Lastly, we describe the two-stage fine-tuning of the multimodal Mamba with our proposed Q-Mamba (Sec. [3.3\)](#page-4-0).

257 3.1 Preliminaries

 State-Space Models (SSMs) [\(Gu et al.,](#page-8-0) [2021,](#page-8-0) [2022a;](#page-7-0) [Smith et al.,](#page-9-8) [2023\)](#page-9-8) represent linear time- invariant systems that map a continuous 1- 261 dimensional function or a sequence $x(t) \in \mathbb{R}$ to **a corresponding response** $y(t) \in \mathbb{R}$, via a hid-263 den state $h(t) \in \mathbb{R}^N$ with N latent dimensions. These systems are characterized by four parameters (A, B, C, D), which define the system dynamics and outputs as follows:

$$
h'(t) = \mathbf{A}h(t) + \mathbf{B}x(t)
$$

267

$$
y(t) = \mathbf{C}h(t) + \mathbf{D}x(t)
$$
 (1)

268 Typically, the parameter D is omitted as it can be **269** interpreted as a skip connection, which is computa-**270** tionally straightforward to implement.

 In practice, to deal with discrete-time input se-**quences, SSMs** are discretized with matrices \overline{A} **and** \overline{B} **. One common discretization method is the** Zero-Order Hold (ZOH) method, outlined as:

$$
\overline{\mathbf{A}} = \exp(\Delta \mathbf{A})
$$

275

$$
\overline{\mathbf{B}} = (\Delta \mathbf{A})^{-1}(\exp(\Delta \mathbf{A}) - \mathbf{I}) \cdot (\Delta \mathbf{B})
$$
 (2)

where the parameter Δ specifies the discretization 276 step size. The reformulated discretized system is **277** given by: **278**

$$
h_t = \overline{\mathbf{A}} h_{t-1} + \overline{\mathbf{B}} x_t
$$

$$
y_t = \mathbf{C} h_t
$$
 (3)

(3) **²⁷⁹**

Structured State-Space Model (S4) [\(Gu et al.,](#page-7-0) **280** [2022a\)](#page-7-0) operates as a time-invariant system, mean- **281** ing its defining parameters (A, B, C, Δ) remain 282 [c](#page-7-2)onstant across all time-steps. Mamba [\(Gu and](#page-7-2) **283** [Dao,](#page-7-2) [2023\)](#page-7-2) addresses this constraint by making B, **284** C, and Δ input-dependent, enabling a dynamic gat- 285 ing mechanism based on the input sequence. This **286** allows Mamba to selectively focus on pertinent **287** information, significantly enhancing its language **288** modeling capabilities. 289

3.2 Cross-Modal Mamba Projector **290**

We propose the cross-modal projector, named Q- **291** Mamba, which integrates the Mamba architecture **292** with cross-attention. The architecture of Q-Mamba **293** is shown in the left side of Figure [2.](#page-3-2) Q-Mamba **294** comprises stacked Q-Mamba blocks, each contain- **295** ing a Mamba layer, cross-attention, and a feedfor- **296** ward network. The Mamba layer functions as a se- **297** quence mixer, while the feedforward network func- **298** tions as a channel mixer. The set of learnable query **299** embeddings is utilized as the input sequence of the **300** Q-Mamba. The queries form causal dependencies **301**

Figure 3: Example of local attention mask applied in the cross-attention layer inside Querying Mamba with 4 queries (Q) and 9 keys (K) . Each query attends exclusively to K/Q keys, enabling the focused extraction of information from distinct visual components.

 through the sequential Mamba layers, then inter- act with vision features from the frozen pre-trained vision encoder through cross-attention layers. For the cross-attention, we found that applying local attention mask as in Figure [3](#page-4-1) empirically enhances the model performance.

 This design offers three key advantages for cross- modal projection. The first advantage is its inde- pendence from visual scan order. Previous Mamba- based vision encoders relied on heuristic choices of visual scan order, such as bidirectional or cross- directional scans [\(Qiao et al.,](#page-9-2) [2024;](#page-9-2) [Zhu et al.,](#page-9-1) [2024;](#page-9-1) [Liu et al.,](#page-8-2) [2024b\)](#page-8-2). Q-Mamba eliminates this dependency by using cross-attention to project vi- sion information from arbitrarily ordered image fea- tures onto a one-dimensional query sequence. The second advantage is the flexible choice of query sequence length. Direct application of Mamba on vision feature sequences typically yields pro- jected features of equivalent length, which may be too extensive even for Mamba LLM. Our design, however, facilitates effective downsampling of the vision feature length. Finally, the architecture's re- semblance to the Q-Former [\(Li et al.,](#page-8-6) [2023a\)](#page-8-6) from transformer-based MLLMs ensures proper align-ment of text-image features.

 We explore several architectural variants to identify the optimal configuration for Q-Mamba. Our investigation includes the use of bidirectional Mamba for preprocessing visual features, the in- corporation of a feedforward network for channel mixing, and determining the optimal length of the learnable query sequence. The findings are detailed in Section [4.3.](#page-6-0)

3.3 Multimodal Mamba Language Model **336**

We introduce the MLLM based on our querying 337 cross-modal projector (Q-Mamba). As shown in **338** Figure [3.2,](#page-3-1) the overall architecture consists of a pre- **339** trained vision encoder, our cross-modal projector, **340** and a pre-trained Mamba LLM. Initially, visual fea- **341** tures are extracted from the input image using the **342** vision encoder. These features are then processed **343** by our projector, which outputs queries embedded **344** with projected visual information. Subsequently, 345 this output sequence is combined with a tokenized **346** text prompt and fed into the Mamba LLM, which **347** generates the corresponding text response. **348**

Training We adopt a two-stage training scheme 349 from LLaVA [\(Liu et al.,](#page-8-7) [2023\)](#page-8-7), where the ini- **350** tial stage involves aligning the projected features **351** within the frozen LLM using a filtered visual **352** instruction-following dataset. The subsequent **353** stage entails end-to-end fine-tuning of both the **354** projector and the LLM using an extensive visual **355** instruction-following dataset. **356**

4 Experiments **³⁵⁷**

4.1 Settings 358

Datasets For the fine-tuning stage, we follow the **359** existing two-stage training paradigm and dataset **360** based on LLaVA [\(Liu et al.,](#page-8-7) [2023\)](#page-8-7) with additional **361** datasets. For the alignment stage, we use a filtered **362** dataset from CC3M with 595K image-text pairs. **363** For the end-to-end fine-tuning stage, we use the 364 combined dataset consisting of LLaVA v1.5 mixed **365** dataset [\(Liu et al.,](#page-8-7) [2023\)](#page-8-7) with 655K visual con- **366** versations, LVIS-Instruct-4V [\(Wang et al.,](#page-9-9) [2023\)](#page-9-9) **367** dataset with 220K context-aware visual instruction **368** pairs, and LRV-Instruct dataset [\(Liu et al.,](#page-8-17) [2024a\)](#page-8-17) **369** with 400K visual instruction pairs aimed for hallu- **370** cination mitigation. **371**

Models For the pre-trained vision encoder, we **372** employ pre-trained SigLIP [\(Zhai et al.,](#page-9-6) [2023\)](#page-9-6), **373** which encodes vision features for each patched 374 image. We utilize a ViT structure with 400 mil- **375** lion parameters. The input image resolution is **376** configured at 384×384 , and the total number of 377 visual features is 729. We also attached a bidi- **378** rectional multimodal connector from trained VL- **379** Mamba [\(Qiao et al.,](#page-9-2) [2024\)](#page-9-2) to the vision encoder. **380** The output of the multimodal connector is used as **381** a vision feature input for the Q-Mamba projector. **382**

The backbone of our model is the pre-trained **383** Mamba [\(Gu and Dao,](#page-7-2) [2023\)](#page-7-2) LLM, which consists **384**

Table 1: Comparison with Multimodal Mamba LLMs on 6 benchmarks: VQA^{v2} [\(Goyal et al.,](#page-7-4) [2017\)](#page-7-4), GQA [\(Hudson](#page-8-18) [and Manning,](#page-8-18) [2019\)](#page-9-10), VizWiz [\(Gurari et al.,](#page-8-19) [2018\)](#page-8-19), VQA^T (TextVQA) [\(Singh et al.,](#page-9-10) 2019), POPE [\(Li et al.,](#page-8-20) [2023b\)](#page-8-20), and MMB (MMBench) [\(Yuan Liu,](#page-9-11) [2023\)](#page-9-11). * indicates the results were reproduced. We also examined variants of the previous Multimodal Mamba LLMs: + forward scan only and + backward scan only indicate the visual scanning order of multimodal connector inside VL-Mamba [\(Qiao et al.,](#page-9-2) [2024\)](#page-9-2). We also report the time consumed per fine-tuning iteration in seconds.

 of 2.8 billion parameters. This model was initially [p](#page-9-12)re-trained on the SlimPajama datasets [\(Soboleva](#page-9-12) [et al.,](#page-9-12) [2023\)](#page-9-12) for 600 billion tokens, instruction- tuned on the UltraChat 200K dataset [\(Ding et al.,](#page-7-5) [2023\)](#page-7-5), and then fine-tuned on the UltraFeedback dataset [\(Cui et al.,](#page-7-6) [2023\)](#page-7-6) using Direct Preference Optimization (DPO) [\(Rafailov et al.,](#page-9-13) [2023\)](#page-9-13).

 For the Q-Mamba projector, we stack 24 blocks with an inner dimension of 768. This choice of hyperparameter is to copy the pre-trained weights of Mamba [\(Gu and Dao,](#page-7-2) [2023\)](#page-7-2) with the size of 130M parameters.

 Training We train the model using four NVIDIA A100 80GB GPUs. During training, we leverage [t](#page-9-14)he PyTorch Fully Sharded Data Parallel [\(Zhao](#page-9-14) [et al.,](#page-9-14) [2023\)](#page-9-14) framework, utilizing automatic mixed- precision with FP32 and BF16 for efficient dis- tributed training. The batch sizes are set to 256 for the alignment stage and 128 for the end-to-end fine-tuning stage. We employ the Rectified Adam (RAdam) optimizer [\(Liu et al.,](#page-8-21) [2020\)](#page-8-21), coupled with a cosine decay learning rate scheduler. The learn-**ing rates are set at** 1×10^{-4} for the alignment stage **and** 2×10^{-5} for the end-to-end fine-tuning, both with a warmup ratio of 0.03. Each training stage is conducted in a single epoch.

 Evaluation To validate the performance of our model, we benchmarked it against five different [d](#page-8-18)atasets: VQA-v2 [\(Goyal et al.,](#page-7-4) [2017\)](#page-7-4), GQA [\(Hud-](#page-8-18) [son and Manning,](#page-8-18) [2019\)](#page-8-18), VizWiz [\(Gurari et al.,](#page-8-19) [2018\)](#page-8-19), Text-VQA [\(Singh et al.,](#page-9-10) [2019\)](#page-9-10), POPE [\(Li](#page-8-20) [et al.,](#page-8-20) [2023b\)](#page-8-20) and MMBench [\(Yuan Liu,](#page-9-11) [2023\)](#page-9-11). Each dataset offers unique challenges and measures

different aspects of the model's capabilities: **418**

- VQA-v2 [\(Goyal et al.,](#page-7-4) [2017\)](#page-7-4) evaluates the **419** model's general ability to reason over Vision- **420** Question pairs. **421**
- GQA [\(Hudson and Manning,](#page-8-18) [2019\)](#page-8-18) extends **422** VQA-v2 by testing the model's reasoning **423** skills across a broader spectrum, incorporat- **424** ing spatial understanding and multi-step infer- **425** ence along with various reasoning skills. **426**
- VizWiz [\(Gurari et al.,](#page-8-19) [2018\)](#page-8-19), similar to VQA- **427** v2, includes unanswerable questions, thereby **428** assessing the model's ability to identify when **429** a question cannot be answered. **430**
- Text-VQA [\(Singh et al.,](#page-9-10) [2019\)](#page-9-10) specifically **431** measures the model's proficiency in recogniz- **432** ing text within images and answering related **433** questions. **434**
- POPE [\(Li et al.,](#page-8-20) [2023b\)](#page-8-20) differentiates itself **435** by focusing on the model's susceptibility to **436** hallucination problems. It provides a score 437 based on the probability of the given answer, **438** hence evaluating the likelihood that the model **439** avoids generating incorrect information. **440**
- MMBench [\(Yuan Liu,](#page-9-11) [2023\)](#page-9-11) evaluates the **441** multi-modal capabilities of vision-language **442** models across 20 distinct abilities, including **443** object localization, social reasoning, and fine- **444** grained perception. It introduces a novel Cir- **445** cularEval strategy, ensuring comprehensive **446** evaluation through multiple passes of QA to **447** reduce biases and improve reliability. **448**

Table 3: Comparison between using bidirectional multimodal connector inside vision encoder from scratch or from trained VL-Mamba [\(Qiao et al.,](#page-9-2) [2024\)](#page-9-2). We used 256 learned queries and local attention for both models.

Table 4: Comparison between using raster scan only or bidirectional multimodal connector inside vision encoder from trained VL-Mamba [\(Qiao et al.,](#page-9-2) [2024\)](#page-9-2). We used 729 learned queries and local attention for both models.

449 4.2 Results

 As presented in Table 1, our model consistently out- performs previous state-of-the-art Mamba-based multimodal models across all benchmarks. Specifi- cally, the Q-Mamba with 729 queries achieves the highest overall performance, demonstrating signif- icant improvements in tasks that require nuanced vision-language integration. Notably, our model shows remarkable gains in the VizWiz and Text- VQA datasets, which assess the model's ability to understand and interpret textual information within **460** images.

 The results indicate that increasing the number of queries generally improves performance. For instance, moving from 128 to 256 queries results in substantial performance gains across all bench- marks, highlighting the importance of having a sufficient number of queries to capture detailed vi- sual information. Further increasing the number of queries to 512 and 729 continues to improve performance, though the gains are less pronounced compared to the initial increase. This suggests that while more queries help in capturing more informa- tion, there is a point of diminishing returns where additional queries contribute less to overall perfor-**474** mance.

475 Compared to Cobra and VL-Mamba, the Q-**476** Mamba design proves to be more effective in dynamically downsampling visual token sequences **477** and eliminating the need for manual visual scan **478** orders, contributing to higher throughput and better **479** alignment of visual and textual information. The **480** flexibility in choosing the query sequence length **481** allows for a tailored balance between computa- **482** tional efficiency and model performance, making **483** Q-Mamba adaptable to various application require- **484** ments. 485

4.3 Ablation Studies **486**

In our ablation study, we meticulously analyzed **487** various configurations to determine how different **488** components within Q-Mamba affect model per- **489** formance. Our initial investigations focused on **490** the type of cross-attention mechanism employed, **491** with results detailed in Table [2.](#page-6-1) These findings 492 demonstrate that local attention significantly out- **493** performs global attention in enhancing model per- **494** formance. We then evaluated the effect of utilizing **495** pre-trained weights for the bidirectional Mamba **496** connector within the vision encoder, with outcomes **497** presented in Table [3.](#page-6-2) The results confirm that lever- **498** aging weights from a trained VL-Mamba model **499** leads to performance improvements. Finally, we **500** explored the influence of the visual scan order in 501 the bidirectional Mamba connector, as shown in **502** Table [4.](#page-6-3) Interestingly, our data indicate that al- **503**

 though the model is trained with a bidirectional scan setting, employing only a forward Mamba for inference does not decrease performance and can even enhance it.

⁵⁰⁸ 5 Conclusion

 This paper presents a query-based cross-modal pro- jector designed to enhance Mamba's efficiency in multimodal vision-language modeling. By using the cross-attention mechanism between the learn- able queries and the outputs of the visual encoder within a Mamba architecture, the proposed mul- timodal projector dynamically compresses visual tokens based on an input image context, eliminat- ing the need for manually designing of the 2D scan order of image features. Experimental results on diverse vision-language understanding benchmarks demonstrate that the proposed cross-modal pro- jector boosts the effectiveness of Mamba-based **522** MLLMs.

⁵²³ Limitations

 Despite the promising results, our approach has several limitations that need to be addressed in future work. The primary limitation is related to the amount and quality of the dataset used for training and fine-tuning the model.

 For the alignment process, we used the LLaVA- LLVIS dataset, and for the fine-tuning process, we used the LLaVA-1.5 dataset. Both of these datasets are filtered and curated to ensure quality, but their limited size compared to the vast datasets typically used in training large language models (LLMs) can restrict the model's ability to generalize across di- verse vision-language tasks. Specifically, we ran one epoch for each stage of our training process, whereas other models in the same domain were fine-tuned for two epochs instead of one. This dif- ference in training duration can result in less robust model performance, as the additional epochs in other models allow for more comprehensive learn-ing and fine-tuning of the parameters.

 Additionally, the Mamba architecture are liable to "forget." The hidden states of the Mamba model take input and output sequentially, similar to how hidden states within the RNN would, where the cur- rent state depends on the previous inputs and hid- den state outputs. This sequential dependency can potentially result in forgetting issues that plagued the RNN/LSTM-based models, if the input would be long enough.

It would be also necessary to pretrain the pro- **553** posed Q-Mamba more thoroughly including con- **554** trastive learning as used in Q-Former based on **555** image-text pair datasets. In addition, the param- **556** eters of Q-Mamba can be initialized by the pre- **557** trained compact Mamba LLM. Also, it would be **558** helpful to perform more in-depth analysis on the **559** resulting attention map for each query according to **560** different input images. 561

Potential Risk **⁵⁶²**

This paper presents a new architecture of a Large **563** Language Model with over a billion parameters, **564** which can cause potential discrimination in the use 565 of these methods due to the disparity in access to **566** computational resources. Also, the hallucination **567** of Large Language Model can cause potential bias **568** or harm when generating response. **569**
