

Graph Convolutional Networks and Text Integration for Recommender Systems

Anonymous ACL submission

Abstract

We present a new model KeywordSage which consists of integration in text data and Graph Convolutional Networks for recommender systems. This model extracts keyword in most efficient way from user reviews text using language model based on Transformer and then Graph Convolutaionl Networks is efficiently trained to learn about user-item interactions by utilizing extracted keywords. This makes it possible to reflect meaningful information from users and utilize it for representing the user-item interaction. We prove that our model is more efficient showing that KeywordSage result in better performance even with significantly fewer learning steps compared to existing models. Our approach is to be a meaningful contribution in that it proposes a new recommender systems by combining Natural Language Processing and a graph-based neural networks, suggesting a direction for covering research in both fields.

1 Introduction

In the field of recommender systems, Collaborative Filtering, Content-based filtering, and Matrix Factorization have been studied actively as traditional methodologies. These trends show that recommendation systems have been recognized as a very important task in many real-worlds. Recently, as deep learning has been revolutionizing dramatically in the overall field of society, the research on personalized recommender systems based on artificial neural networks has also been actively studied (Sun et al., 2019; He et al., 2017; Sarwar et al., 2001; Hidasi et al., 2015). In this study, we propose a new recommender systems model using artificial neural networks that can provide personalized recommendation services by accurately understanding users and items characteristics, and complex interactions.

KeywordSage, which we propose, effectively extracts meaningful keywords from user review text

through language model based on Transformer. Afterwards, the extracted keywords and interactions between users and items are learned using an artificial neural network based on Graph Convolutional Neural Networks. With this structure, our model learned meaningful interactions between users and item characteristics, which resulted in providing more accurate and faster personalized recommendation services.

Graph Convolutional Networks (GCN), based on graph structure, is one of the key research areas that has recently attracted attention in the field of artificial neural networks. Hamilton et al. (2017b) presented that expressing data with a complex connection structure in a graph structure consist of nodes and edges, and learning this with a Graph Neural Network (GNN), is a effective methodology for learning the representation. And this increases the applicability of GNNs in various fields such as social networks, molecular structure prediction, etc. Monti et al. (2017) present the potential of graph structured artificial neural network showing that multi-graph neural networks can effectively model the geometric characteristics of data. Berg et al. (2017) deal with the Matrix Completion using a graph structure and show the results of effectively solving the problem in the recommender systems by implementing a system that predicts the rating a user gives to an item. These research show the potential for development of Graph Neural Network for recommendder systems and suggest directions for implementing better recommendation algorithms and personalized services.

The field of Natural Language Processing (NLP) is also one of the areas that has recently attracted attention in the field of artificial neural networks. The possibilities of language models are attracting more attention appearing Large Language Models such as GPT (Radford et al., 2018), LLAMA (Touvron et al., 2023). From the traditional methodology, Term Frequency-Inverse Document Frequency

(TF-IDF), to the artificial neural network models Word2Vec (Mikolov et al., 2013) and FastText (Bojanowski et al., 2017) models, previous methodologies mainly consider only the frequency of words or only the context around words when they learn the representation. On the other hand, a language model based on Transformer (Vaswani et al., 2017) understands the entire context and learns representation much more effectively through Attention mechanism. Therefore, in this paper, we seek to extract meaningful keyword information from user review through a Transformer-based language model and implement a recommendation system using this.

The contributions of this study are as follows:

- Proposal of new model for recommender systems based on keyword-centered and graph structure: Effectively extracts keywords from user review through Transformer-based methodology and uses this to propose a model for recommender systems that learns user-item interaction through Graph Convolutional Neural Networks.
- Combining various research fields: This methodology, developed by combining the latest research in natural language processing and graph neural networks in the field of recommender systems, suggests the possibility of convergence between various research fields and suggests a new direction for recommendation algorithms.
- Establishing a research foundation for recommender systems based on text: By proposing a method to approach a recommender systems using text, it can serve as a cornerstone for future research on recommender systems using text.

In Section 2, we review previous research on recommender systems and Transformer-based language model. In Section 3, we explain in detail the overall structure and pipeline of our proposed model. In Section 4, we discuss experiments and results and, In Section 5, we discuss future research.

2 Related Works

In this part, we will briefly review previous studies. Topics related to this study include general recommender systems, Graph Convolutional Networks for recommender systems, and Transformer-based language model.

2.1 General Recommender Systems

Collaborative Filtering, Content-based Filtering, and Matrix Factorization have traditionally been studied as methodologies in the field of recommender systems. Collaborative Filtering analyzes user behavior records to group users with similar preferences and provides recommendations based on group preferences. Content-based filtering analyzes the characteristics of items and recommends new items based on the user's previous preferences. Matrix Factorization decomposes the user-item matrix to discover hidden factors and provide recommendations to the user. These traditional methodology mainly analyzes existing data and models it using statistical methodology.

Artificial neural network-based methodologies have attracted attention because they can increase non-linearity and model more complex interactions. Hidasi et al. (2015) present Recurrent Neural Networks (RNN) model using the online session data of users to model the user's session in chronological order and uses this to recommend items. He et al. (2017) propose that by combining matrix decomposition techniques and neural network models in a collaborative filtering-based recommendation system, recommendation accuracy has improved and a personalized recommendation system can be implemented. Therefore, recommender systems based on artificial neural network have overcome the limitations and limitations of traditional recommendation systems and presented new perspectives and possibilities to provide more personalized recommendations to users.

2.2 Graph Convolutional Networks for Recommender System

As proven in numerous studies, Graph Convolutional Networks show excellent performance in efficiently extracting and representing information using convolutional operations in a graph structure.

Hamilton et al. (2017b) present study focusing on efficient representation learning of GNN using graph structure and applicability in various fields, and Monti et al. (2017) has proven to effectively model data geometric characteristics through multiple neural networks. Chen et al. (2018) announce the FastGCN model, a model based on Graph Convolutional Networks that introduce the Importance Sampling method, which is a graph synthesis tool that achieves high computational efficiency at a faster speed by selectively selecting the nodes nec-

181 essary for neural network learning.

182 GraphSAGE (Hamilton et al., 2017a) and Pin-
183 Sage (Ying et al., 2018) models are notable studies
184 that implemented a personalized recommendation
185 system considering user-item interactions using
186 Graph Convolutional Neural Networks. PinSage
187 follows the basic structure of GraphSAGE and pro-
188 poses a method of learning large-scale graph struc-
189 tures and optimize GPU using effective sampling
190 and learning techniques such as Importance Sam-
191 pling and Curriculum Training.

192 LightGCN (He et al., 2020) is a model that made
193 meaningful contributions by proposing a graph-
194 structured recommendation system with good per-
195 formance while simplifying the graph convolu-
196 tional neural networks. By using a single layer to
197 consider only user-item interaction and implement-
198 ing an embedding learning method without scaling,
199 LightGCN simplified the model and showed simi-
200 lar performance to other complex models. Also the
201 self-connection effect is derived through an embed-
202 ding parameter learning method and the possibility
203 of improving the over-smoothing problem is pre-
204 sented.

205 The model proposed in this paper follows a basic
206 structure to the Graph Convolutional Networks of
207 the GraphSage and PinSage models.

208 2.3 Transformer in Natural Language 209 Processing

210 Language models based on Transformer (Vaswani
211 et al., 2017) have brought innovation to the field
212 of Natural Language Processing (NLP). Starting
213 with Bidirectional Encoder Representations from
214 Transformers (BERT) (Devlin et al., 2018), vari-
215 ous Transformer-based language models such as
216 DistilBert (Sanh et al., 2019), Roberta (Liu et al.,
217 2019), and sentence-Bert (??) have emerged. The
218 efficiency and accuracy of the language model have
219 been proven through a lot of research. These mod-
220 els effectively calculate word embedding within
221 sentences through Token Embedding, Segment Em-
222 bedding, and Positioning Embedding that take con-
223 text into account. Additionally, through Attention
224 mechanism, interactions between words within a
225 sequence of sentence are understood and important
226 information is extracted. Therefore, in this paper,
227 Sentence-Bert, which is a Transformer-based lan-
228 guage model, is used to calculate keywords from
229 text.

3 Method 230

231 In this Section, we introduce the overall structure
232 and pipeline of the KeywordSage model, which we
233 suggest. The structure of KeywordSage consists of
234 a total of two stages. Keyword extraction based on
235 Transformer is preformed in Stage-I, and Graph
236 Convolutional Networks is trained based on the
237 bipartite graph structure of the data reflecting the
238 extracted keyword in Stage-II.

3.1 Keyword Extraction (Stage-I) 239

240 The Stage-I of the KeywordSage model which is
241 the first stage of the methodology is described in
242 this section. This includes the process of efficiently
243 extracting keywords from customer review text
244 data.

245 In order to extract meaningful keywords from
246 text data, keywords are selected by considering the
247 similarity between words in a sentence. Based on
248 the N-gram, trigram is set as the basic unit of text
249 and the most frequent trigram in the review text
250 is calculated. It is assumed that frequently appear-
251 ing keywords are representative of whole review.
252 One set is created with the most frequent keywords,
253 and another set is created by dividing the entire
254 text review into trigram units. These two sets are
255 used as encoder input values for Sentence-Bert,
256 and the similarity is compared. Sentence-Bert has a
257 Siamese Network structure and it help that allows
258 different sentences A and B to pass through each
259 encoder layer and then calculates the similarity of
260 the results. The output of the encoder layers pass
261 through the mean pooling layer to calculate sen-
262 tence embedding, and the similarity is calculated
263 using cosine similarity for each of these values u
264 and v . Cosine Similarity is defined as the following
265 equation (1) and Table 1 shows sample keyword
266 extraction for a customer review.

$$267 \text{CosineSimilarity} = \frac{u \cdot v}{\|u\| \|v\|} \quad (1)$$

3.2 Graph Convolutional Networks (Stage-II) 268

269 In Stage-II, The structure and learning process of
270 Graph Convolutional Networks is explained.

271 The Stage-II begins by importing the keywords
272 finally output in the previous Stage-I as attributes
273 of the user node. This forms a complete bipartite
274 graph structure to be used as input to the convo-
275 lution layer. The formed graph passes through the
276 projection layer and becomes the input of the Graph
277 Convolutional Layer.

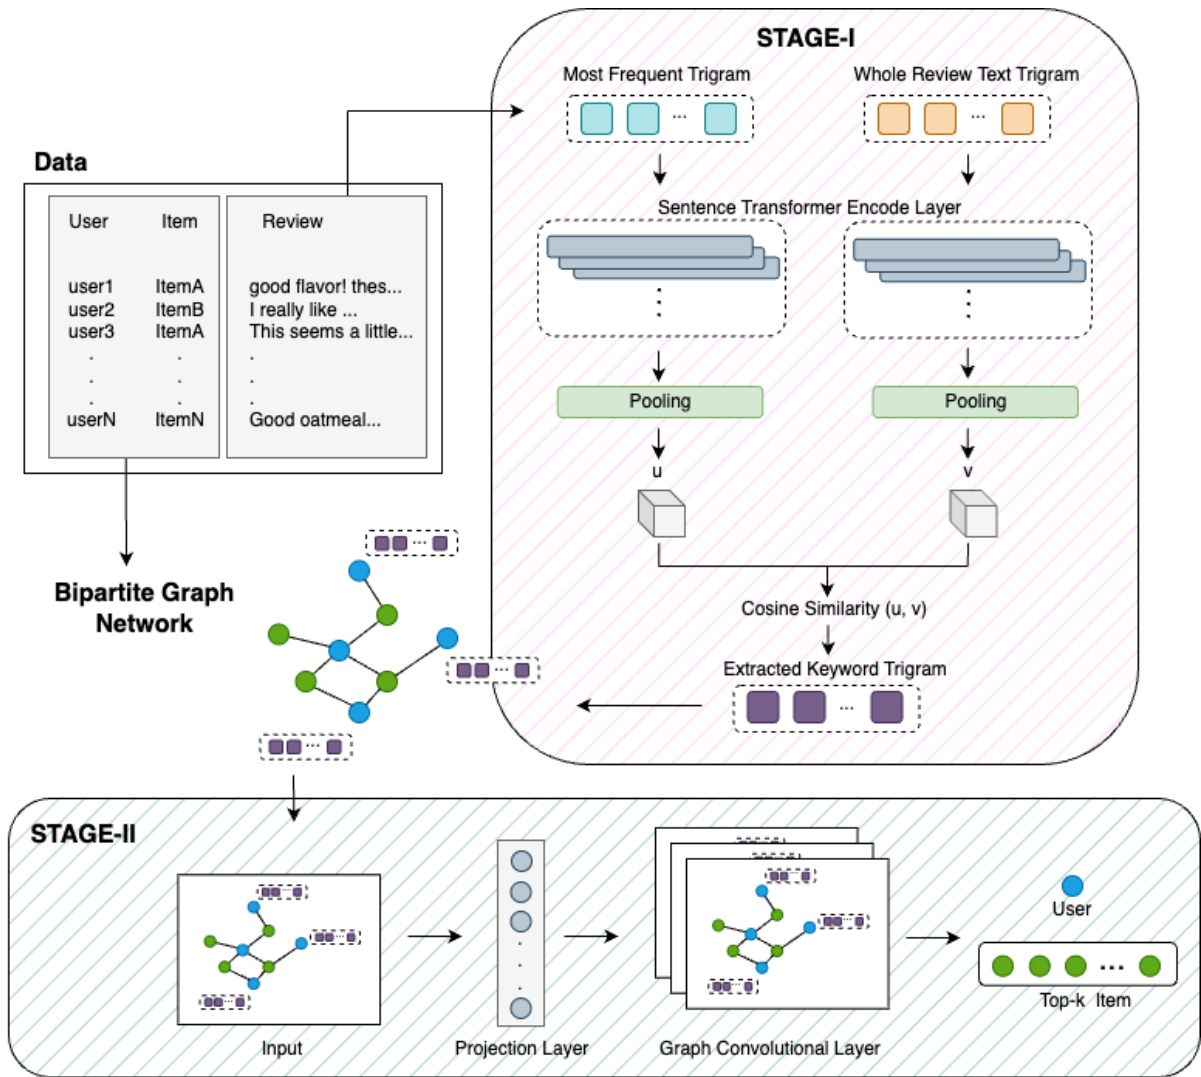

Figure 1: This is the first figure.

Review	I simply fell in love with these chips and refused to share them with my friends :) My experience with a lot of cheese-favored chips has been too salty and a little over the greasy side. But these NY cheddar from Kettle really changed my mind. Thanks to Amazon for great discounts and I don't have to buy them from the store anymore.
Extracted Keyword	'amazon great discounts', 'experience lot cheese', 'greasy ny cheddar'

Table 1: This shows the examples extracted keyword from review. we use three keywords in trigram units for each review in our experiment.

The purpose of Graph Convolutional Networks is to produce high-quality embedding results for users and items and to use them in recommendation systems. The graph structure is consisted as a bipartite graph with the user node set U and item node set I . An interaction edge exists only between two different types of nodes u and i . The node set of entire graph is denoted as $V = U \cup I$.

Graph Convolutional Networks is trained about node embedding by repeatedly aggregating feature information from each node's neighbors. By stacking multiple convolution layers, it becomes possible to expand the receptor field to extract wider neighborhood information and reflect the structural information of the graph. The input of each convolution layer depends on the representation output from the previous layer. The first layer has the same characteristics as the input node. Model parameters are shared between nodes, but the values

297 have different values for each layer. The output
 298 of the last k-th convolution layer passes through
 299 a fully-connected neural network to generate the
 300 final embedding.

301 For sampling process, the on-the-fly convolu-
 302 tion method is used to sample neighboring nodes,
 303 and the Importance-Based Neighborhoods tech-
 304 nique is used to sample them using distance in-
 305 formation. On-the-fly convolution technique helps
 306 the graph structure learn quickly by implement-
 307 ing localized graph convolution that samples lo-
 308 cally nearby nodes rather than processing the en-
 309 tire graph node at once. The Importance-Based
 310 Neighborhoods, which samples important neigh-
 311 bors by considering connectivity and weights be-
 312 tween nodes, helps select and learn items that users
 313 interact with or meaningful neighbors of those
 314 items.

315 4 Experiments

316 In this chapter, we describe the experiments per-
 317 formed to verify our research. We will explain the
 318 datasets used in the experiment, the experimental
 319 environment, and the experimental results.

320 4.1 Datasets

321 The Amazon Product Review datasets(He and
 322 McAuley, 2016; McAuley et al., 2015) is used for
 323 this experiments. This datasets categorizes prod-
 324 ucts into 29 detailed categories, and the data from
 325 the Grocery and Gourmet category is used for this
 326 study. This data consists of user information, in-
 327 formation about the items the user purchased, text
 328 reviews written by the user, product ratings, and
 329 information about the time the review was written.
 330 We only use the data when the user interacted with
 331 at least 10 items.

332 When this datasets is converted to a bipartite
 333 graph, there are 7,323 user nodes, 27,251 item
 334 nodes, and a total of 137,696 interactions between
 335 users and items.

336 4.2 Settings Evaluation Metrics

337 The Max-Margin Ranking Loss is used as loss func-
 338 tion for training. This is learned to minimize the
 339 inner product of query q and positive samples, and
 340 maximize the inner Positive sample(z_i)refers to the
 341 interaction with an item that has a purchase record
 342 from an actual user, negative sample(z_n) refers to
 343 interactions with items for which the actual user
 344 has no purchase record. Max-Margin Ranking Loss

345 for the query vector $q(z_q)$ to be predicted is de-
 346 fined as the following equation (2). In this study,
 347 we follow the loss function proposed in PinSage
 348 model.

$$349 \begin{aligned} JG(z_q, z_i) = E_{n_k \sim P_{n(q)}} \max \{ & 0, z_q \cdot z_{n_k} \\ & - z_q \cdot z_i + \Delta \} \end{aligned} \quad (2)$$

350 To efficiently perform Graph Convolutional Net-
 351 works training, a producer-consumer mini-batch
 352 construction distributed processing pipeline is built
 353 in the experiments. Training is performed in a mini-
 354 batch using a predefined computational graph to
 355 efficiently perform SGD learning. In addition, train-
 356 ing is performed using the Efficient MapReduce
 357 method and the curriculum training is used during
 358 the learning process to enable progressively more
 359 difficult learning data to be trained. These tech-
 360 niques help improve the computational efficiency
 361 and performance of learning.

362 4.3 Results

363 To evaluate the experimental results, we use the
 364 evaluation metrics Recall, Precision, and Hit-ratio
 365 which are widely used in recommender system re-
 366 search. Recall is indicator of how well the model
 367 recommended items are included among actual re-
 368 lated items. Precision measures the proportion of
 369 actually relevant items among the items recom-
 370 mended by the model. Hit-ratio is an indicator
 371 that measures how many items a user actually pur-
 372 chased are included in a specific recommendation
 373 list. These three evaluation indicators can comple-
 374 ment each other to evaluate the model’s perfor-
 375 mance. For example, Recall can identify whether
 376 the model found many related items, but there is
 377 a lot of noise among them, also when precision
 378 is high, most of the items recommended by the
 379 model are highly relevant, but in reality, there are
 380 items missed. In this study, we use these indicators
 381 to evaluate and analyze the performance of model
 382 which we proposed.

383 4.4 Implementation Details

384 The experiment is run in an NVIDIA Telsa K80
 385 GPU and Cuda 11.4 version. ADAM Optimizer is
 386 set as the optimization. To prevent over-smoothing,
 387 where the embedding vector excessively converges
 388 to the average of local information when multi-
 389 ple convolution layers are stacked, dropout is set
 390 to 0.5. The experimental results introduced in the

Model	Recall@20	Precision@20	Recall@30	Precision@30
PinSage	0.605	0.448	0.676	0.344
KeywordSage*	0.624	0.462	0.677	0.345

Table 2: Comparison table of experiment results. Our proposed model KeywordSage is marked with *.

next section are the results of staking two Graph Convolutional Layers.

Table 2 shows a comparison of the results of the PinSage model and our proposed model, the KeywordSage model. What is important in this table is that the results of the PinSage model proposed in existing research took a much longer learning period. The results of the PinSage model were achieved by running more than 20,000 learning epochs, and the results of the KeywordSage model were achieved by running the learning epochs 3000 times. This verifies that the model we propose is showing better results by significantly reducing the learning time. Additionally, when comparing the evaluation metrics, it can be seen that there is an improvement of 0.019 in Recall@20, 0.014 in Precision@20, and 0.003 in HR@20 of KeywordSage model. In particular, it is figured out that the performance difference between the two models widens in the Recall score.

5 Conclusion and Future Work

In this study, we propose a model called KeywordSage that provides recommender services using text data based on Graph Convolutional Networks. This successfully models user-item interaction by utilizing Transformer-based keyword extraction and Graph Convolutional Networks. Our experimental results show that this model leads to improved results at a faster rate compared to the existing model PinSage.

Additionally, this study proposes the convergence of various fields such as recommender systems, natural language processing, and graph neural networks. Therefore, we expect that research on the convergence of Natural Language Processing and Graph Neural Networks will be able to expand into broader and more effective collaborative research in the future based on this study. Future research will especially need to study recommendation systems based on text data. With the emergence of Large Language Models(LLM), the speed of language model development is growing rapidly, and the potential to utilize text data and expand application areas in line with these changes

is endless. Many industries currently have an enormous amount of text data accumulated. This data exists in many forms, such as consumer reviews, product descriptions, social media opinions, and more. In comparison, the amount of data we currently use is just fragments of a vast amount of information. Therefore, in the future, we expect to be able to propose a model that can increase the accuracy and quality of personalized services by focusing on research that can maximize the value of such data and the application potential of language models.
